Background: Relebactam (REL) is a diazabicyclooctane inhibitor of class A and C β-lactamases, including Klebsiella pneumoniae carbapenemase (KPC), approved in the United States (US) in combination with imipenem (IMI) and cilastatin for treatment of complicated intra-abdominal and urinary tract infections. First reported in 1996, KPC is an important mechanism of carbapenem nonsusceptibility in hospital-acquired infections. An analysis of IMI/REL in vitro efficacy for KPC encoding Enterobacterales was undertaken.

Materials/methods: The Study for Monitoring Antibacterial Resistance Trends (SMART) is an ongoing worldwide surveillance study that has evaluated consecutive clinical isolates from intraabdominal, urinary, and lower respiratory tract sources since 2002. A total of 1696 sequenced Enterobacterales KPC isolates were studied from SMART and additional referred clinical isolates. MICs to IMI and IMI/REL (fixed 4 mg/L) were determined by broth microdilution and interpreted using CLSI breakpoints, with the exception of IMI/REL, for which US Food and Drug Administration (FDA) breakpoints were used. The KPC sequence subtype was determined by PCR and sequencing.

Results: The percent IMI and IMI/REL susceptibility for all KPC isolates (N=1696) was 1.9% and 95.4% while that for KPC-2 was 1.9% and 95.0% and for KPC-3 was 0.6% and 96.4%. Of 1684 sequenced KPC-encoding Enterobacterales the most frequent sub-types were KPC-2 (67.2%) and KPC-3 (31%); all other sub-types combined were 1.8%. The geometric mean (GEOMEAN) MIC (mg/L) for IMI and IMI/REL for sub-types with N>10 isolates were: KPC-2 (N=113), 1.70 and 0.31, respectively; KPC-3 (N=522), 18.5 and 0.26, respectively; KPC-17 (N=12), 8.1 and 0.30, respectively. The co-carriage of KPC and OXA-48-like genes in Enterobacterales was rare accounting for just under 1% of the total in 2015, 2017, and 2018. Of 11 isolates encoding KPC and OXA-48-family enzymes, susceptibility was 0% to IMI and 63.6% to IMI/REL. The co-carriage of KPC and metallo-β-lactamase genes has increased, from 0 in 2015/2016 to 1.6% of KPC-encoding Enterobacterales in 2018.

Conclusions: IMI/REL could provide an important treatment option for patients with infections caused by KPC-expressing Enterobacterales. There was little difference in GEOMEAN MIC for KPC allele sub-types. Percent susceptibility remained high when OXA-48-like enzymes were co-carried with KPC.

Abstract 4146

Optimised positioning of carbapenem-sparing options for treatment of UTIs by molecular antibiotic susceptibility testing

Nicholas Adomakoh¹, Norhan Mahfouz², Patrick Harris³, François Franceschi⁴, Andrew Henderson¹, Stephan Beisken², Eva Littringer¹, Andreas Posch*²

¹Sandoz International GmbH, Holzkirchen, Germany, ²Ares Genetics GmbH, Vienna, Austria, ³University of Queensland, Brisbane, Australia, ⁴GARDP – Global Antibiotic Research & Development Partnership, Genève, Switzerland

Background: Escherichia coli and Klebsiella pneumoniae account for approximately 75% of all urinary tract infections (UTI) globally. Due to increasing rates of antimicrobial resistance (AMR) against first-line treatment options as well as carbapenems, the use of “old” antibiotics such as fosfomycin or drug-combinations has been identified as a promising alternative.

Materials/methods: 91 Escherichia coli and 107 Klebsiella pneumoniae from the FDA-CDC AR isolate bank were subjected to fosfomycin susceptibility testing via agar dilution. Antibiotic susceptibility profiles were additionally downloaded from the FDA-CDC AR collection as well as genetically derived by interpretation of whole-genome sequencing data via ARESdb, a unique AI-powered knowledgebase of genetic AMR prediction models trained on next-generation sequencing (NGS) data for 35,000+ isolates and susceptibility data for 100+ drugs.

Results: Fosfomycin was found to be superior over carbapenems in both multi-drug resistant target pathogens. Optimizing for negative correlation between AMR phenotypes for fosfomycin and potential combination options, amikacin was identified as promising combination candidate with the combination showing 98% and 75% efficacy in multi-drug resistant Escherichia coli and Klebsiella pneumoniae respectively (Fig. 1). Using genetic AMR prediction facilitated by ARESdb, we further show that molecular antibiotic susceptibility testing is feasible with high accuracy for common UTI treatment options exceeding 90% categorical agreement with culture-based antibiotic susceptibility testing (AST) across various antibiotic drug classes in this proof-of-concept study.

Conclusions: We here describe fosfomycin either alone or in combination with amikacin as promising carbapenem-sparing option for treatment of UTIs and show that molecular drug response detection for clinical isolates is feasible by combining NGS with AI-powered data interpretation. As a multi-disciplinary consortium, we further aim at developing a molecular test for the accurate drug response detection in UTIs. The underlying molecular marker panels will be applicable to rapid testing of native patient samples, enabling patient stratification for clinical trials and informed empirical therapy.

Fig. 1: Fosfomycin outperforms carbapenems and shows high efficacy with amikacin in multi-drug resistant Escherichia coli and Klebsiella pneumoniae. Only the last-line treatment option tigecycline was found to have higher efficacy in both major UTI pathogens, with the combination of fosfomycin and amikacin outperforming colistin in Escherichia coli.

Subtyping of adenovirus strains isolated from pre-diagnosed patients with keratoconjunctivitis

Ayfer Güner1, Aysegul Karahasan1, Rabia Can Sarıoğlu1, Fahri Onur Aydin2, Ebru Toker2, Semra Akkaya Turhan2

1Marmara University Pendik Training and Research Hospital, Medical Microbiology, Istanbul, Turkey, 2Marmara University Pendik Training and Research Hospital, Ophthalmology Clinic, Istanbul, Turkey

Background: We investigated the presence and subtypes of human adenovirus (hAdV) in conjunctival swab samples taken from patients clinically diagnosed as keratoconjunctivitis and to evaluate the efficacy of infection control measures in the polyclinics.

Materials/methods: Samples (n=113) were sent to clinical microbiology laboratory in January 2018 to November 2019. The nucleic acid extraction and amplification were performed by ELIte InGeniusTM instrument (ELITechGroup, Italy) using quantitative real-time PCR method. Sequencing primers were targeted the conserved segments of the ‘Hypervariable Region 7’ (HVR-7) of the hexon gene. DNA sequence analysis was performed with ABI PRISM® 3100 Genetic Analyzer (Applied Biosystems, USA). The obtained hAdV DNA sequences were typed by BLAST analysis and the genotypes were identified by using the reference hAdV sequences of the NCBI.

Environmental swab samples were also collected from ophthalmoscopy device, patient seat, physician desk, sink, door knob of the rooms to evaluate the efficacy of disinfection and the risk of cross-contamination. Training on disinfection procedures was given to the personnel.

Results: Of 113 conjunctivitis cases, 82 (72.5%) were HAdV positive with the median (IQR): 7,1 (4,7-7,4) log 10 copies/mL viral load. Three genotypes were identified from 72 hexon gene positive samples and the most common genotypes were hAdV-8 (n: 69, 95.8%), followed by hAdV-4 (n: 2, 2.8%) and hAdV-19 (n: 1, 1.4%). As seen in phylogenetic tree, there was no predominant genetic relatedness between strains.

Conclusions: Very high hAdV positivity rate (72.5%) in our study was related with detailed clinical examination and proved once more the importance of physician-microbiologist collaboration. Even during summer outbreaks, strains were not related with each other and probably the source was not common. We screened the environment in ophthalmology polyclinics and trained the personnel to overcome cross contamination and these precautions prevented HAdV transmission between patients.

**Impact of hypoalbuminemia and augmented renal clearance on flucloxacillin plasma concentrations: a real-life retrospective study**

Deborah Marriott*1, Andrew Duckworth2, Graham Jones3, Cindy Lau3, Dario Cattaneo4

1Sydney, St. Vincent’s Hospital, Darlinghurst, Australia, 2Liverpool, The Liverpool Hospital, Sydney, Australia, 3Sydney, St. Vincent’s Hospital, Sydney, Australia, 4ASST FBF Sacco University Hospital, Milan, Italy

**Background:** S. aureus is the ‘consummate pathogen’ with significant morbidity and 20-30% mortality overall whilst S. aureus endocarditis is associated with mortality rates up to 70% despite the availability of highly active anti-staphylococcal antibiotics. Flucloxacillin is the antibiotic of choice for treatment of methicillin-sensitive S. aureus in many countries. This drug is characterized by a >95% binding to plasma protein (mainly albumin) and renal excretion. Here we aimed to characterize the pharmacokinetics of flucloxacillin in patients with hypoalbuminemia or altered renal function.

**Materials/methods:** Flucloxacillin therapeutic drug monitoring (TDM) was undertaken using a validated LC/MS-MS assay. Contemporaneous renal function (glomerular filtration rate estimated using the CKD-EPI formula, eGFR) and albumin were measured in the routine chemistry laboratory. A flucloxacillin trough target range (total drug) of 20-80 mg/L was recommended in local hospital guidelines.

**Results:** 505 patients had flucloxacillin concentrations measured over a 4-year period. Overall 55% fell within the target range. 335/505 had albumin measured and 352/505 had an eGFR calculated at the time of the first flucloxacillin TDM. Whilst the average flucloxacillin concentration rose as albumin fell there was no clear relationship between serum albumin levels and flucloxacillin concentration (R=0.137, P>0.05). Conversely, a significant inverse association was found between eGFR and flucloxacillin concentration (r=-0.459, p=0.033) with augmented renal clearance (eGFR 120-180 mL/min/1.73m²) resulting in a mean flucloxacillin trough concentration of 21.3 mg/L versus 79.1 mg/L for eGFR 0-30 mL/min/1.73m² (p=0.015). 42% of patients with eGFR 0-30 mL/min/1.73m² had a concentration>80 mg/L.

**Conclusions:** Despite being highly protein bound serum albumin concentrations did not affect the mean flucloxacillin concentration. Therefore the serum albumin at the time of presentation is not an indication to alter the standard flucloxacillin dosing regimen. Conversely the eGFR was a strong predictor of flucloxacillin concentrations. Patients with augmented renal clearance require enhanced dosing regimens to achieve therapeutic concentrations whilst patients with impaired renal function may need a dose reduction to avoid drug toxicity.

Abstract 4152

Variations in categorical agreement between fosfomycin agar dilution and disk diffusion using standard and high inoculum protocols for Klebsiella pneumoniae testing
Amanda Krueger¹, Hunter Brigman¹, Jadyn Anderson¹, Elizabeth Smith¹, Elizabeth B. Hirsch*¹
¹University of Minnesota College of Pharmacy, Minneapolis, United States

Background: FOF has been used in the treatment of multidrug-resistant K. pneumoniae (KP) infections despite established susceptibility breakpoints. Using disk diffusion (DD) susceptibility testing, it has been observed that inner colonies (IC) are frequent in KP testing. Furthermore, recent discussions surrounding interpretation of DD have highlighted the differences in Clinical and Laboratory Standards Institute (CLSI) and European Committee on Antimicrobial Susceptibility Testing (EUCAST) guidelines, with CLSI stating to measure from the inner-most colonies, and EUCAST stating to ignore inner colonies and measure from the edge of the full coverage zone. We sought to assess the categorical agreement between FOF agar dilution (AD) and DD susceptibility testing methods against KP isolates and to assess the presence of IC.

Materials/methods: Minimal inhibitory concentration (MIC) values were determined for a convenience collection of 55 KP isolates from 2 US institutions. MIC testing was conducted in duplicate on separate days using AD and DD methods. Fifteen isolates were also analyzed using AD at a higher inoculum of 10⁵-10⁶ CFU/mL, similar to the broth microdilution method. MIC values were categorized using CLSI interpretive criteria for E. coli (≤64 mg/L, susceptible). The frequency of IC was determined, and DD was measured in accordance with EUCAST guidelines for FOF against E. coli.

Results: MIC values varied widely, ranging from 4->256 μg/mL for AD, with zone diameters of 6-24mm for DD. AD MIC₅₀/MIC₉₀ values were 32/256 mg/L. Using E. coli criteria, susceptible/intermediate/resistant rates were 85.4%/3.6/10.9 (AD) and 87.3%/9.1/3.6 (DD). Categorical agreement was 80%. IC were present in 82% of isolates, with 22% having ≥5 IC. When using the high-inoculum AD, MIC values were on average 3-fold higher compared to standard inoculum AD. Categorical agreement with DD dropped to 28.9%, with S/I/R rates of 14.2%/42.9/42.9 for the high-inoculum AD.

Conclusions: Categorical agreement between AD and DD was low for the KP isolates resistant by AD and also significantly decreased when a higher inoculum was used. In addition, IC were frequently observed and were ignored, according to EUCAST guidelines. Based on these results, we recommend further investigation of the DD reading methods, and the susceptibility breakpoints for KP.

Abstract 4156

30-day mortality among neonates with candidaemia in a high azole resistance setting, South Africa, 2012-2017

Liliwe Shuping1, Nelesh P. Govender1

1Centre for HAI, AMR, and Mycoses, National Institute for Communicable Diseases, a Division of National Health Laboratory Service, Johannesburg, South Africa

Background: Candida parapsilosis is the leading cause of candidaemia among neonates in South Africa. In this setting, a large proportion of C. parapsilosis strains are resistant to fluconazole, a widely used antifungal agent. We hypothesised that, owing to inappropriate treatment, neonates with C. parapsilosis candidaemia would have a higher risk of death compared to those with bloodstream infections caused by other species.

Materials/methods: We conducted laboratory-based surveillance for neonatal candidaemia over six years (2012–2017). A case was defined as a neonate aged ≤28 days with a single-species Candida bloodstream infection. Identification and antifungal susceptibility testing of viable isolates was performed at a reference laboratory. Clinical information was collected for participants admitted to sentinel hospitals. We used multivariable logistic regression to determine if C. parapsilosis candidaemia was associated with an increased 30-day mortality.

Results: Of 1494 neonates, 1176 (78.7%) had single-species infections. The median age was 14 days (interquartile range, 9-19) and 53% (766/1445) were male. C. parapsilosis accounted for 45% (532/1176) of all cases and 68% (354/523) of C. parapsilosis isolates were fluconazole-resistant compared to 1% (5/493) of other Candida species. Among 859 neonates with treatment data, most were treated with amphotericin B deoxycholate (43%, 366), amphotericin B deoxycholate plus fluconazole (34%, 292) or fluconazole (22%, 191). Of 514 neonates with a central venous catheter (CVC) in-situ, 420 (82%) had this removed after candidaemia diagnosis. Of 620 neonates with available outcome, the crude 30-day mortality was 42% (260/620): 37% (98/262) for C. parapsilosis versus 45% (162/358) for other species (unadjusted odds ratio [OR] 0.72, 95% confidence interval [CI]: 0.52–1.49, p-value=0.05). After adjusting for sex, birth weight, type of feeding, abdominal pathology, mechanical ventilation, any surgery, CVC removal, and prior antibiotic treatment, mortality among neonates with C. parapsilosis candidaemia (versus other species) was reduced by 29% [adjusted OR 0.71, 95% CI: 0.33–1.48, p-value=0.36] though the 95% CI crossed 1.

Conclusions: Despite a very high prevalence of fluconazole resistance, the risk of death was not increased among neonates with C. parapsilosis candidaemia. This may be related to amphotericin B deoxycholate treatment and CVC removal in a majority of cases.

Emergence of another truly multidrug-resistant yeast pathogen, Candida kefyr, in Kuwait
Suhail Ahmad1, Ziauddin Khan2, Noura Al-Sweih2, Wadha Alfouzan3, Leena Joseph1, Mohammad Asadzadeh2
1Faculty of Medicine, Kuwait University, Jabiya, Kuwait, 2Faculty of Medicine, Kuwait University, Jabiya, Kuwait, 3Farwaniya Hospital, laboratory department-Microbiology Unit, Kuwait, Kuwait

Abstract third-party references: Supported by Kuwait University Research Sector grant MI01/1S

Background: Invasive fungal infections (IFI) usually affect immunocompromised and/or immunosuppressed hospitalized patients with or without other co-morbidities. Recent emergence of multidrug-resistant Candida auris, Candida glabrata and few other yeast pathogens is a matter of serious concern due to limited number of antifungal drugs and antifungal drug classes that are available to treat patients with IFI. Candida kefyr, an emerging multidrug-resistant yeast, causes invasive candidiasis in susceptible patients. This study determined the prevalence of C. kefyr among yeast isolates collected during 2011-2018 in Kuwait. Antifungal susceptibility testing (AST), genotypic heterogeneity and molecular basis of resistance to fluconazole and echinocandins among C. kefyr were also determined.

Materials/methods: C. kefyr isolates were identified by CHROMagar Candida, Vitek 2 and PCR amplification of rDNA. Genotypic heterogeneity was determined with microsatellite-/minisatellite-based primers and by PCR-sequencing of IGS1 region of rDNA. AST was performed by Etest. Molecular basis of resistance to fluconazole and echinocandins was studied by PCR-sequencing of ERG11 and FKS1 genes, respectively.

Results: Among 8257 yeast strains, 69 C. kefyr (including four bloodstream and seven other invasive) isolates were detected by phenotypic and molecular methods. Isolation from urine and respiratory samples from female and male patients was significantly different (P=0.001). Fingerprinting with microsatellite-/minisatellite-based primers identified only three types. IGS1 sequencing identified seven (A-F) haplotypes among 27 selected isolates including 18 Haplotype D isolates. Four isolates showed reduced susceptibility to amphotericin B (AMB) and one isolate to all (AMB, fluconazole, voriconazole and caspofungin/micafungin) antifungals tested. Fluconazole-resistant isolate contained wild-type Erg11 protein. Echinocandin-resistant isolate contained wild-type hotspot-1 of FKS1. Based on FKS1 data, additional genotypes were also detected among IGS1 Haplotype D isolates.

Conclusions: Although frequency of isolation of invasive and non-invasive C. kefyr was stable during the study period, four of five isolates with reduced susceptibility to antifungals were obtained during last four years indicating increasing trend of reduced susceptibility to antifungals. The invasive and AMB-resistant isolates were genotypically heterogeneous. The multidrug-resistant isolate likely resulted from mechanisms that confer resistance to multiple drugs.

Abstract 4164

Eliminating mother-to-child transmission of hepatitis B virus in Namibia: a cost-effectiveness analysis

Cynthia Raissa Tamandjou Tchuem1, Monique Andersson1,2, Josef Mufenda3, Charles Wyssonge4, Dorothea Diergaardt4, Wolfgang Preiser2, Susan Cleary1

1University of Cape Town, Division of Health Economics/Health Economics Unit, Cape Town, South Africa, 2Stellenbosch University, Division of Medical Virology, Cape Town, South Africa, 3Oxford University hospitals NHS Foundation Trust, John Radcliffe Hospital, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom, 4Windhoek Hospital Complex, Department of Obstetrics and Gynaecology, Windhoek, Namibia, 5South African Medical Research Council, Cochrane Centre South Africa, Cape Town, South Africa, 6Ministry of Health and Social Services, Division of Family Health, Directorate of Primary Health Care Services, Windhoek, Namibia

Background: Although eliminating mother-to-child transmission (MTCT) of hepatitis B virus (HBV) in sub-Saharan Africa (SSA) is an achievable and laudable aim, the cost implications need consideration. The aim of the study was to determine the costs and health benefits of a screen-treat-vaccinate intervention for preventing HBV MTCT (PMTCT) in Namibia, from the provider’s perspective.

Materials/methods: This analysis was attached to a screen-treat-vaccinate intervention study performed in Windhoek, Namibia. Using a hypothetical cohort of 10 000 pregnant women, decision tree modelling was performed to explore the costs and health benefits of four PMTCT interventions: (1) Universal HBV birth dose (BD) vaccination, (2) screen + vaccinate (BD + hepatitis B immunoglobulin (HBIG)), (3) screen + HBeAg testing + treatment + vaccinate, and (4) screen + HBV viral load testing + treatment + vaccinate. Resources including consumables, healthcare workers’ time, building space and facilities, and hospital utilities were measured. Health benefits were measured as number of pediatric HBV infections averted. Incremental cost-effectiveness ratios (ICERs) were calculated to compare each intervention to the previous less expensive one, and sensitivity analyses were conducted.

Results: Universal BD vaccination was the least expensive (US$15 827.22), but 31 pediatric infections would still be recorded. Adding HBIG prevented an extra 22 infections at an incremental cost of US$98 498.74. Screen-treat-vaccinate was the most effective, with only 3 residual infections. HBeAg testing costed less than HBV viral load testing: US$114 325.96 vs US$153 053.55, respectively. HBV treatment with HBeAg testing had an ICER of US$6 262.42 per infection averted, in comparison to the screen-vaccinate intervention. The latter had an ICER of US$4 550.34 per infection averted. These ICERs were highly sensitive to the prevalence of highly infectious pregnant women, the cost of the HBeAg test, and the effectiveness of each strategy among highly infectious pregnant women. HBsAg rapid testing costed approximately US$6 in comparison to US$18 for laboratory testing.

Conclusions: This is the first study describing the costs and health benefits of antenatal HBV treatment and HBIG for HBV PMTCT in SSA. The study demonstrated that elimination of HBV MTCT is achievable in Namibia, and by extrapolation in SSA.

A multi-national study for the treatment of enterococcal endocarditis with ampicillin-daptomycin combination therapy

Miguel Sierra Hoffman1,2, Rafael J Deliz1, Anupamjeet Kaur Sekhon3,4, Aniruddha Gollapalli4, Kimberly Saddler4, Mark Stevens4, Miriams Castro-Lainez5, Juan M. Pericas6

1Victoria, Texas A&M, Victoria, United States, 2Citizens Medical Center, Victoria, United States, 3UIW School of Osteopathic Medicine, San Antonio, United States, 4DeTar Hospital Navarro, Victoria, United States, 5Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, 6University Hospital Arnau de Vilanova, Lleida, Spain

Background: Enterococcus infective endocarditis continues to pose a significant therapeutic challenge inherited in the 21st century. Traditionally, the standard of care has been combination therapy with ampicillin and an aminoglycoside. The most utilized aminoglycoside sparing combination to date is ampicillin and ceftriaxone for *Enterococcus faecalis*. The past exposure of patients to multiple antibiotics prime this versatile species’ ability to evolve into becoming multidrug-resistant, thereby leaving a therapeutic vacuum in this complicated infection and limiting the existing combination options.

The combination of ampicillin and daptomycin has been successful in a small cohort in the literature, including a solid organ transplant patient. This combination is a promising alternative bringing another regimen that spares the use of aminoglycosides, with a broader therapeutic spectrum, including vancomycin-resistant enterococci.

Materials/methods: We present 34 patients treated with ampicillin-daptomycin for enterococcal infective endocarditis in the last decade. This study is a cross-section study, including three countries. The subspecies were described (Table 1.).

A chart review of patients that met definite and possible modified Duke's criteria in where the use of ampicillin-Daptomycin combination was used as primary or salvage therapy.

Results: The regiment was very effective with 3/34 deaths during admission and 6/38 at 12 months. There were no iv drug users in this population. The data included native and bioprosthetic valves without significant difference between both groups in terms of outcomes. There were no reinfections, relapse or drug discontinuation by adverse effects.

Conclusions: The combination of ampicillin-daptomycin proved to be safe with excellent outcomes and low mortality in Enterococcus faecium infective endocarditis as the initial therapy or when other drugs failed.

Abstract 4166

Differences in clinical characteristics and causative pathogens between central line-associated bloodstream infections and catheter-related bloodstream infections using modified definition in medical intensive care unit

Jonghoon Hyun1, Joon-Sup Yeom1, Jun Yong Choi1, Nam Su Ku1, Su Jin Jeong1, Jin Young Ahn*1

1Yonsei University College of Medicine, Seoul, South Korea

Background: The surveillance definition of central line-associated bloodstream infection (CLABSI) could overestimate the central venous catheter (CVC) as the source of bloodstream infection. The definition of catheter-related bloodstream infection (CRBSI) by the Infectious Diseases Society of America is a more specific definition that identifies the CVC as the source of infection. In this study, we used modified definitions of CRBSI and compared clinical characteristics and causative pathogens between CLABSIs and CRBSIs.

Materials/methods: We retrospectively reviewed all CLABSI data reported in the 30-bed medical intensive care unit (ICU) of Severance hospital between January 2017 and December 2018. We defined CRBSI as simultaneous positive results of blood culture drawn from the central line and peripheral site without other focus of infection and excluding mucosal barrier injury-associated laboratory-confirmed bloodstream infection.

Results: Overall, 105 episodes of CLABSI were reported over 94 patients. Among them, 37 patients meet the diagnostic criteria of CRBSI. CRBSI group had more extended ICU stay (24.00 days vs. 17.95 days) and catheter indwelling time (46.49 days vs. 26 days). Emergent catheter insertion (69.7% vs. 41%), localized sign and symptoms of insertion site (88.2% vs. 30.3%) were more frequent in CRBSI group. Whereas, catheter removal rate for suspected infection was higher in CLABSI group (71.6% vs. 32.3%). Candida species were the most frequently identified causative pathogen followed by Enterococcus species in both groups. However, the proportion of Enterococcus species was lower (21.43 vs. 32.26) in CRBSI group. Despite various efforts to prevent, CLABSI outbreak occurred in the 3rd quarter of 2018. (9.21 per 1,000 catheter line days) However, the incidence of CRBSI was not correlated with CLABSI outbreak.

Conclusions: Our data showed that the current surveillance definition of CLABSI may not always warrant clinical importance. More specified definitions may be necessary to evaluate the effectiveness of interventions or outbreak investigations.

Figure 1. Incidence rate (per 1000 catheter line days) of CLABSI(blue) and modified CRBSI(red)

**New lean preparation method for identification of mycobacteria by MALDI Biotyper**

Markus Timke¹, Arthur Pranada*², Markus Kostrzewa³

¹Bruker Daltonik, Bremen, Germany, ²Überörtliche Berufsausübungsgemeinschaft Medizinisches Versorgungszentrum Dr. Eberhard & Partner Dortmund, Dortmund, Germany

**Background:** The rate of successful identifications of Nontuberculous Mycobacteria (NTM) by MALDI-TOF MS has risen over the past years due to dedicated preparation techniques and expansion of reference libraries. However, MALDI-TOF MS sample preparation of mycobacteria is still laborious and a shortened protocol will be appreciated. Recently, a very fast preparation method for mycobacteria cultivated on solid medium has been published [1]. Here, we present a similar method which also works for cultures grown in liquid medium.

**Materials/methods:** NTM strains were cultivated in MGIT™ [BD] medium. Biomass was transferred to a tube containing four small steel cylinders. After centrifugation the medium was discarded. An inactivation step in 75 % Inactivation Reagent [Bruker-Hain] for 30 minutes followed. After another centrifugation step and removal of the supernatant, 200 µl extraction reagent were added and two cycles of shaking (1 min) were performed. Following a final centrifugation step, 1 µl of supernatant was spotted onto a MALDI target plate, overlaid with 1 µL matrix solution and analyzed in a MALDI Biotyper system.

**Results:** Ten different *Mycobacterium* species, mainly from culture collections, were analyzed in one lab by three different operators. Each strain was identified at high confidence level (log(score) ≥ 1.8). Four strains from clinical samples were processed in another laboratory, all of them were identified at high confidence level as well.

**Conclusions:** Altogether, 27 cultures including 4 clinical samples were reliably identified using the new rapid preparation method. The current dataset is still limited but robustness of the method is underlined by four different operators from two labs. ComParison to the current standard preparation method for mycobacteria [MycoEX] will continue in the clinical routine laboratory.

The new preparation method avoids boiling mycobacteria for their inactivation and needs less hands-on time. This might improve the applicability of MALDI-TOF MS mycobacteria identification in routine laboratories.

Abstract 4169

**Antiviral efficacy of released-active antibodies to interferon gamma against MERS Coronavirus**

Elena Don1,2; Nataliia Petrova*1,2; Koert Stittelaar3; Evgeniy Gorbunov2; Sergey Tarasov1,2

1Institute of General Pathology and Pathophysiology, Moscow, Russian Federation, 2OOO "NPF MATERIA MEDICA HOLDING", Moscow, Russian Federation, 3Viroclinics Biosciences BV, Rotterdam, Netherlands

Abstract third-party references: Supported by OOO "NPF MATERIA MEDICA HOLDING"

**Background:** Antibodies (Abs) are an important component in host immune responses to viral pathogens. That is why Abs-based drugs become more and more widespread in virus-caused conditions' treatment despite the difficulty with creating finished drug formulation with high accessibility and efficacy and low toxicity. Drugs based on released—active (RA) form of Abs is a novel concept to reach these goals. The technology of these drugs' manufacture is represented by combining multiple gradual decrease of Abs to the desired dilution along with physical treatment. Drugs based on RA Abs to interferon gamma (IFNγ) are proven to have confirmed efficacy and safety. The key mechanism of drug action is the ability to regulate the functional activity of endogenous interferons by exerting an allosteric effect on IFNγ structure, which results in modulation of IFNγ affinity to its receptor. Based on this mechanism of action and the coronavirus infection pathogenesis, which affects host immune system responses, RA Abs to IFNγ could be effective against Middle East respiratory syndrome coronavirus (MERS-CoV).

**Materials/methods:** The study was performed at Viroclinics Biosciences. Capacity of RA Abs to IFNγ to suppress MERS-CoV replication was evaluated *in vitro* on Human hepatocellular carcinoma cells (Huh 7). Virus MERS-HCoV/KSA/EMC/2012 was used at the dose of 2Log_{10} TCID50/ml. The reference drug pegylated-interferon α-2b (PEG-IFNα-2b) dose was 100 ng/ml. Cells were treated with drugs 24 hours prior to viral inoculation and replaced after inoculation daily for 7 days post MERS-CoV infection. Viral load was estimated by qPCR. To assess the effects, the generalized linear model and multiple comParison, followed by Tukey-Kramer post-hoc adjustments was implemented.

**Results:** RA Abs to IFNγ were shown to statistically significantly (p<0.001) decrease viral titers in cells infected with MERS-CoV vs control and virus groups. There was no significant difference between reference drug and RA Abs to IFNγ effects.

**Conclusions:** In previous studies, RA Abs to IFNγ was proven to be safe and highly effective against different RNA- and DNA-containing viruses, including pandemic strains. Using this *in vitro* experimental model, RA Abs to IFNγ were shown to have antiviral activity against MERS-CoV that is comparable to the reference drug.

Detection of influenza and non-influenza respiratory viruses detected in lower respiratory tract specimens of hospitalised adult patients and analysis of the clinical outcome
Ching Hao Hsu*1, Hsin-Pai Chen1

1Taipei Veterans General Hospital, Internal medicine department, Taipei, Taiwan

Background: Lower respiratory tract (LRT) infection remains one of the most fatal infections for adults. Influenza virus has been a well-recognized cause of severe pneumonia. The outcome of LRT infections caused by other respiratory viruses (RVs), however, has been insufficiently investigated.

Materials/methods: A retrospective review of medical records was performed on adult patients whose LRT specimens, including endotracheal aspirate and broncho-alveolar lavage fluid, were positive for respiratory viruses by multiplex PCR (Luminex, Canada). Underlying comorbidities, laboratory data, and clinical outcome were analyzed.

Results: Of the total 808 LRT samples collected from 666 adult patients, 166 samples from 152 patients had at least one RV identified. After exclusion, 106 patients were included in the study. The underlying comorbidities and laboratory data were not different between patients with influenza and non-influenza RVs infection. On survival analysis, mortality rates estimated at 14 days and 30 days were higher in the influenza group than in the non-influenza-RV group (P=0.026 and P=0.020, respectively), and influenza was associated with a marginally higher 90-day mortality rate (P=0.063). The mortality rates between individual viruses were also different, although the highest mortality rate was also observed in patients with influenza (P=0.343). Diabetes mellitus, a CRP level higher than 5mg/dl upon sample collection, and shock and acute kidney injury during the hospital course predicted a higher mortality rate. Use of steroid in disease course did not show a survival benefit (P=0.916). In a multivariate Cox model, shock and acute kidney injury independently predicted a higher mortality rate (hazard ratio: 4.28, 95% CI: 1.46–12.58, P= 0.008 and hazard ratio: 2.80, 95% CI: 1.28–6.15, P=0.010, respectively).

Conclusions: Respiratory viruses other than influenza are important pathogens of LRT infection in adults and may cause significant mortality. Novel antiviral agents should be developed to combat these potentially life-threatening viral infections.

Usefulness of escalation therapy in urinary tract infection caused by extended beta-lactamase-producing Escherichia coli with bacteremia

Tatsuya Shindo*1, Hiroaki Nishioka1

1Kobe City Medical Center General Hospital, Kobe, Japan

Background: In Japan, the detection rate of extended spectrum beta-lactamase (ESBL)-producing Escherichia coli has been increasing yearly. For ESBL-producing bacteria, broad-spectrum antimicrobial agents are often used for empiric therapy, but there is a risk of promoting further antibiotic resistance. In this study, we investigated whether delaying the initiation of effective antibiotic administration would lead to poorer outcome in urinary tract infection (UTI) caused by ESBL-producing E. coli with bacteremia.

Materials/methods: This is a single center retrospective study on adult patients aged ≥18 years who were detected with ESBL-producing E. coli by blood and urine cultures between April 2014 and July 2018. Of the 95 patients, 43 patients who met the criteria for sepsis under Sepsis-3 were excluded in the study. The patients were classified into the following groups based on whether the E. coli was resistant or susceptible to the antibiotic selected in empiric therapy: resistant group (n=27) and susceptible group (n=25). The following outcomes were assessed: hospital mortality, length of hospital stay, and rate of discharge to home. ESBL was detected using the double-disc synergy test.

Results: In the resistant group, ceftriaxone was mainly used for empiric therapy, and it took an average of 2.4 days until effective antibiotics were administered. The hospital mortality rate was 0% in both groups. The median length of hospital stay was 11 (2–62) days in the resistant group and 17 (4–86) days in the susceptible group, and the length of hospital stay was significantly shorter in the resistant group (p<0.05). The rate of discharge to home was 44% (12/27) and 52% (13/25) in the resistant and susceptible groups, respectively, but the difference was not statistically significant (p=0.78).

Conclusions: In cases of UTI caused by ESBL-producing E. coli, even with bacteremia, if the criteria for sepsis are not met, outcomes are unlikely to deteriorate even if the patient is switched to an effective antibacterial drug after determining the susceptibility. Hence, the coverage of ESBL-producing bacteria in empiric therapy may not be necessarily required for such patients.

Abstract 4173

The frequency of diarrhoeagenic Escherichia coli isolates in children with acute diarrhoea under five years
Aysegul Koc¹, Hatice Turk Dagı*¹

¹Selcuk University, Faculty of Medicine, Department of Medical Microbiology, Selcuk University, Konya, Turkey

Background: The detection of diarrheagenic Escherichia coli isolates from normal intestinal microbiota is important for the diagnosis and treatment of acute diarrhea. There is no research and data about the frequency of diarrheagenic E. coli pathotypes in Turkey. This study aims to detect the frequency of diarrheagenic E. coli pathotypes [enteropathogenic E. coli (EPEC), enterotoxigenic E. coli (ETEC), enteroinvasive E. coli (EIEC) Shiga toxin-producing E. coli (STEC), enterohemorrhagic E. coli (EHEC), enteroaggregative E. coli (EAEC) and diffuse adherence E. coli (DAEC)] in children with acute diarrhea under five years in Konya/Turkey.

Materials/methods: Between January and October 2019, E. coli strains isolated from stools of 259 children without any other pathogen were identified by conventional methods and Vitek 2 automated system. DNA isolation was performed with a commercial kit. The primers of eae, pEAF, daaC, otaA, elt, est, ipaH, stx1, and stx2 genes were studied by real-time multiplex PCR method. Detection of eae plus pEAF genes was accepted typical EPEC (tEPEC), only eae atypical EPEC (aEPEC), stx1 and/or stx2 genes STEC, eae plus stx1 and/or stx2 genes EHEC, elt and/or est genes ETEC, ipaH gene EIEC, otaA gene EAEC and daaC gene DAEC. Results were confirmed by monoplex PCR and gel electrophoresis.

Results: Of the 259 specimens, 46 had single and 213 had mixed pathotypes. DAEC was detected in 232, tEPEC/aEPEC in 145, EAE in 121, EIEC in 43, EHEC in 31, ETEC in three and STEC in two samples. The most common single pathotypes were DAEC [39], and EAEC [5], and mixed types were DAEC plus tEPEC/aEPEC [49], DAEC plus tEPEC/aEPEC plus EAEC [32], DAEC plus EIEC [24], DAEC plus EHEC [13].

Conclusions: DAEC was single and DAEC plus tEPEC/aEPEC were mixed predominant pathotypes in the diarrheagenic E. coli isolates in children with acute diarrhea under five years in Konya/Turkey. This is the first study to investigate all diarrheagenic E. coli pathotypes in Turkey. The study is still ongoing and preliminary data were presented here. The most important limitation of our study is that it is single-centered. Multicentre studies are needed to determine which pathotypes are common in Turkey.

Abstract 4174

**Fosfomycin for the treatment of neonatal sepsis**

Phoebe Williams*1,2, James A Berkley1,2, Obiero Christina2, Sheila Murunga2, A. Sarah Walker1, Borna Nyaok2, Raymond Omollo2, Sally Ellis2, Erika Correia3, Mike Sharland4

1 The University of Oxford, Oxford, United Kingdom, 2 KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, 3 GARDP, Geneva, Switzerland, 4 St George’s University, London, United Kingdom

**Abstract third-party references:** The Global Antibiotic Research Development Program (GARDP)

**Background:** Antimicrobial resistance (AMR) is a global health problem that threatens the Sustainable Development Goals for child mortality. There are published data indicating high rates of resistance to WHO-recommended empirical regimens for treating neonatal sepsis. Fosfomycin has been identified as a ‘critically important’ antibiotic for combating AMR. An off-patent antibiotic, fosfomycin has significant potential for treating neonatal sepsis yet there are minimal published safety or pharmacokinetic (PK) data in the neonatal population, and dosing regimens are poorly evidence-based.

**Materials/methods:** As part of the Global Antibiotic Research and Development Programme (GARDP) strategy we performed a Phase 1, un-blinded, prospective randomised trial to investigate the safety and pharmacokinetics of fosfomycin in 120 hospitalised neonates with clinical sepsis in Kilifi County Hospital, Kenya (NeoFosfo; ClinicalTrials.gov: NCT03453177). Eligible participants were randomised (1:1 ratio) to receive WHO standard-of-care antibiotics (SOC; ampicillin & gentamicin) or SOC plus fosfomycin (100mg/kg/dose twice daily). Parenteral antibiotics were continued until clinically indicated, at which point participants were de-escalated to oral fosfomycin (100mg/kg/dose twice daily) to complete their treatment course. Safety endpoints were plasma sodium concentration and adverse events (any grade) experienced during a 28-day follow-up period. PK sampling followed a cross-over design; samples were analysed using population-based non-linear mixed effects modelling.

**Results:** There was no significant difference between the two treatment arms with regards to serum sodium (difference in mean change 0.75mmol/L, 95% CI -1.28 to 2.78, p=0.43), potassium (difference in mean change -0.33mmol/L, 95% CI -0.08 to 0.73, p=0.83), liver function or renal function following IV fosfomycin administration. Despite oral fosfomycin’s fructose load, only one infant (2%) experienced diarrhoea (Grade 2). Adverse events (any grade) were less frequent in the group receiving fosfomycin (n=31 v’s n=42 in SOC). There were no serious adverse drug reactions attributed to fosfomycin. PK analysis revealed a two-compartment model with standard allometric and post-menstrual scaling provided a good fit to support baseline PK parameters.

**Conclusions:** Fosfomycin appears to be a safe antibiotic for treating neonatal sepsis which does not impact serum sodium levels or increase the frequency of antibiotic-associated gastrointestinal symptoms. Population-based PK modelling has defined appropriate dosing regimens to treat neonatal sepsis.

Abstract 4175

Lipid profile change in HIV naïve patients treated with therapy tenofovir alafenamide-based

Loredana Alessio*1, Salvatore Martini2, Paolo Maggi3, Lorenzo Onorato4, Sergio Ferrara1, Vincenzo Esposito4, Giovanni Di Filippo5, Addolorata Masiello6, Renato Santoro7, Viviana Rizzo8, Chiara Bellacosa6, Angelo Iodice1, Nicola Coppola1

1AORN Sant’anna e San Sebastiano, Caserta, Italy, 2University of Campania “Luigi Vanvitelli”, Naples, Italy, 3Università degli studi di Foggia, Foggia, Italy, 4AORN Dei Colli, Naples, Italy, 5Università degli studi di Napoli Federico II, Napoli, Italy, 6AO San Giuseppe Moscati di Avellino, Avellino, Italy, 7San Giovanni di Dio e Ruggi d’Aragona, Salerno, Italy, 8A.O San Pio, Benevento, Italy

Background: The advent of Tenofovir alafenamide (TAF) has improved long-term bone and kidney tolerability of antiretroviral treatment. However, some data in the literature show an increase in lipids after switching from TDF to TAF. Our aim is to investigate if TAF is associated with higher lipid levels than the abacavir/lamivudine regimen in the treatment of naive HIV patients

Materials/methods: We enrolled 185 naive HIV patients who had a follow-up at least 24 weeks after starting therapy. The exclusion criteria were the use of TDF or protease inhibitors. Patients were divided in relation to the type of regime adopted: TAF/FTC/RIL [Group A], TAF/FTC/EVT/Cobi [Group B], TAF/FTC/INI [Group C] and ABC/3TC/DTV, without TAF and Cobicistat [Control Group]. We evaluated triglycerides, cholesterol, HDL and LDL levels. The groups of cases were compared with the Control group analysing the baseline data (T0), 24 weeks (T1) and 48 weeks (T2) of follow-up, although the data at T2 were incomplete. The endpoint was evidence of dyslipidemia and/or the introduction of statin treatment.

Results: There were no differences between Cases and Baseline Control. At T1 and T2, we observed a higher incidence of hypercholesterolemia in TAF groups, not associated with alteration of LDL and HDL values. At the multivariate analysis to analyse the factors associated with hypercholesterolemia in T1 and T2, only age was significantly associated with this parameter.

Conclusions: Our preliminary data show that, in HIV naïve patients, TAF can be associated with hypercholesterolemia after 48 weeks of follow-up compared to baseline values in the same group, and in any case the older age of patients plays a priority role for dyslipidemia. This figure should be confirmed in subsequent analyses and although the clinical significance is still unclear, it may be an important focus for patient management.

Activity of ceftolozane/tazobactam against prevalent Gram-negative pathogens across Asia: PACTS 2016-2018

Merrin Tulloch*1, Dee Shortridge2, Mary Motyl3, Pamela Moise3, Wei-Ting Chen4

1MSD Australia, Sydney, Australia, 2JMI Laboratories, North Liberty, United States, 3Merck, Kenilworth, United States, 4MSD Taiwan, Taipei, Taiwan

Background: Ceftolozane/tazobactam (C/T) is an anti-pseudomonal cephalosporin combined with a β-lactamase inhibitor, recently approved for treatment of hospital acquired pneumonia, including ventilator associated bacterial pneumonia (VABP) in adults. The Program to Assess Ceftolozane-Tazobactam Susceptibility (PACTS) surveillance study monitors C/T resistance worldwide.

In this study, we sought to characterise susceptibility of C/T against the predominant Gram-negative pathogens in Asian countries.

Materials/methods: The susceptibility of ceftolozane/tazobactam and comparator antimicrobial agents [amikacin (AMK), cefepime (FEP), ciprofloxacin (CIP), colistin (COL), gentamicin (GEN), meropenem (MEM), piperacillin/tazobactam (P/T)] was evaluated by broth microdilution, using EUCAST criteria, against 2,545 Gram-negative clinical isolates collected from hospitals participating in the PACTS study across eight countries (Japan, Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand, Vietnam) between 2016 and 2018.

Results: The most common Gram-negative pathogens identified were E. coli (n=716, 28.1%), K. pneumoniae (n=547, 21.5%), P. aeruginosa (n=376, 14.8%), and A. baumannii (n=274, 10.8%).

Susceptibility of E. coli to C/T was >84.0% in all Asian countries (93.6% overall) whereas K. pneumoniae susceptibility ranged from 42.1% in Vietnam to 100% in Japan and Singapore (67.8% overall). Susceptibility of P. aeruginosa ranged from 71.4% in Vietnam to 97.3% in Taiwan; overall susceptibility was 91.0% across Asia.

Among P. aeruginosa isolates resistant to CAZ, FEP, P/T, MEM or MDR phenotypes, C/T showed highest susceptibility of all agents tested (56.8%, 48.4%, 67.1%, 45.5%, and 56.4% respectively), except colistin.

A. baumannii was the fourth most common organism collected (n=274, 10.8%), and was the most frequently identified pathogen among patients with VAP or in the ICU. In all countries where more than 30 A. baumannii isolates were collected (Korea, Malaysia, Taiwan, Thailand, Vietnam), MEM resistance was at least 75.0%. C/T MICs reflect carbapenem resistance, being under 8 μg/ml for all MEM-susceptible and over 4 μg/ml for all MEM-resistant A. baumannii isolates.

Conclusions: Overall, C/T demonstrated consistently high activity against E. coli, but substantial variability between countries for K. pneumoniae. C/T was highly potent against P. aeruginosa and maintained good activity against P/T-resistant and MEM-resistant P. aeruginosa isolates collected in Asia. These data support consideration for clinical use in Asia, particularly for resistant P. aeruginosa infections.

Abstract 4177

Direct identification of Candida species from positive blood culture by MALDI-TOF MS using a commercial pretreatment kit

Yuka Yamagishi1, Tetsuo Mouri1, Hiroyuki Suematsu1, Amiko Masuya2, Kazuho Ashizawa2, Yohei Shimpo1, Hiroshige Mikamo1

1Aichi Medical University, Aichi, Japan, 2Nitto Boseki Co., Ltd., Tokyo, Japan, 3Nittobo Medical Co., Ltd., Tokyo, Japan

Background: Candidemia, induced by the presence of Candida species in blood stream, is a major cause of morbidity and mortality in clinical care. Early species identification and treatment is imperative given the disease’s invasive nature. Our hospital routinely utilizes MALDI-TOF MS identification directly from positive blood cultures. However, direct identification of Candida species nevertheless presents a significant challenge in clinical settings. In this study we evaluated a commercial pretreatment kit rapid BACpro II for direct identification of Candida species from clinical samples.

Materials/methods: Positive blood culture bottles of Candidemia were acquired from Aichi Medical University’s microbiology lab. Following standard protocol, 55 bottles were processed by rapid BACpro II (Nittobo Medical, Tokyo Japan). To improve its performance, protocol of rapid BACpro II was modified to process a larger culture volume with no alteration to reagent volume. 6 bottles were then processed by the modified protocol. MALDI-TOF MS was performed using Bruker Biotyper Smart system set to Sepsityper analysis mode.

Table: Clinical performance of rapid BACpro II in processing Candidemia blood culture bottles

Results: The rapid BACpro II gave proper ID to a majority of clinical samples demonstrating its clinical competence (Table). An increase in sample volume lead to ID scores above 1.8 for all the samples processed.

Conclusions: Efficient isolation of microorganisms by rapid BACpro II is achieved by the binding of cationic polymers to the microbes. Its performance on the clinical Candidemia samples offers a promising potential for early Candidemia intervention and opens the door to the protocol's standardization in the future.

Abstract 4178

High prevalence of azithromycin-resistant *Mycoplasma genitalium* in both urogenital and anal samples in men and women

Joyce Fallon Braam1, David Hetem2, Jean-Marie Brand3, Martijn Van Rooijen1, Clarissa Vergunst1,6, Sophie Kuizenga-Wessel1, Alje Van Dam1,6, Sylvia Bruisten1

1Public Health Service of Amsterdam, Department of Infectious Diseases Research and Prevention, Amsterdam, Netherlands, 2Haaglanden Medical Center, Department Medical Microbiology, The Hague, Netherlands, 3 Public Health Service of The Hague, Department of Infectious diseases, The Hague, Netherlands, 4NWZ, Department of Dermatology, Den Helder, Netherlands, 5Academic Medical Center, Amsterdam, Netherlands

Abstract third-party references: Department of Infectious Diseases Research and Prevention, Public Health Service of Amsterdam, Amsterdam, the Netherlands

Background: *Mycoplasma genitalium* (MG) is a sexually transmitted bacterium associated with urethritis in men. Macrolide resistance in MG is increasing and limiting treatment options. In this study, the prevalence of macrolide resistance in MG was determined from different anatomical sample locations.

Materials/methods: In 2018, urogenital and anal samples from symptomatic and asymptomatic clients visiting STI clinics in Amsterdam or The Hague were tested for MG, *Neisseria gonorrhoeae* (NG) and *Chlamydia trachomatis* (CT) using TMA assays (Aptima, Hologic). MG positive samples were tested using an in-house validated MG macrolide resistance detection PCR.

Results: We included samples from 402 clients with MG; 256 urogenital and 237 anal samples. Co-infection with CT occurred in 56/402 (13.9%) clients and with NG in 40/402 (10.0%) clients. Macrolide sensitivity of MG infections was determined in 326/493 (66.1%) samples of different anatomical locations from 291 clients. There was no significant difference in the sensitivity of resistance determination of different anatomical sample locations (table 1). From 34 clients, macrolide resistance-associated mutations were detected in samples from two different anatomical locations. Three clients (8.8%) had macrolide sensitive MG at one location and macrolide resistant MG at the other location. Infection with resistant MG was detected in 193/291 (66.3%) clients. Prevalence of macrolide resistant MG was significantly higher in men (178/291, 72.5%) compared to women (113/291, 56.6%) (p=0.005). Macrolide resistance was higher, although not significant, in clients co-infected with NG 26/38 (68.4%, p=0.091), but not in clients with CT co-infection 25/38 (65.8%).

Conclusions: Macrolide resistance is very high in clients infected with MG, especially in men. If treatment is considered, testing for macrolide resistance is essential.

**Abstract 4179**

**Recurrence of multidrug-resistant *Klebsiella pneumoniae* ST48 at Charité, Universitätsmedizin Berlin**

Friederike Maechler¹, Anna Weber*¹, Petra Gastmeier², Axel Kola²

¹Charité - Universitätsmedizin Berlin, Institute of Hygiene und Environmental Medicine, Berlin, Germany

**Background:** In summer 2019, Charité - Universitätsmedizin Berlin (CUB), a 3 000-bed hospital with 3 facilities located in different districts of the city of Berlin, experienced an outbreak of multi-drug resistant (MDR) *K. pneumoniae* (Kpn) sequence type 48 (ST48) expressing the carbapenemase OXA-48 at one of its hospital sites located in the South of Berlin. This outbreak involved 8 patients on two ICUs transferring patients among themselves. Of note, a similar cluster of Kpn ST48 was observed at one of the other CUB hospital sites in 2014.

To understand the underlying epidemiology, we tested the following hypotheses:

1. The same strain of Kpn ST48 persisted and spread between the hospital sites of CUB since 2014
2. Kpn ST48 is (hyper)endemic within the Berlin region and was repeatedly introduced to CUB

**Materials/methods:** To investigate these two hypotheses, we used subsets of MDR Kpn ST48 isolates that were i) cultured during active surveillance admission screening (09/2018-03/2019), ii) cultured in the course of different repPCR-confirmed local outbreaks (12/2016-01/2019), and iii) which tested positive for OXA-48 with PCR (03/2017-08/2019). In total, 33 Kpn isolates underwent Whole Genome Sequencing (WGS) using Nextera XT DNA library preparation, the MiSeq system (Illumina Inc., San Diego, USA) and cgMLST (SeqSphere+ 6.0.2, Ridom GmbH, Muenster, Germany).

**Results:** Only one of the 33 MDR Kpn was classified as ST48 (isolated in 2016 from a patient with no epidemiological relation to the cluster in 2014).

**Conclusions:** Spread of Kpn ST48 within the Berlin region and local spread within CUB seems to be unlikely. WGS analysis did not reveal an epidemiological linkage between the cluster in 2014 and the outbreak in 2019 at CUB.

**Presenter email address:** anna.weber@charite.de
**Nephrotoxicity during teicoplanin therapy in combination with piperacillin/tazobactam or other anti-pseudomonal β lactams**

Chihhsun Tai*, Chihao Shao*, Chichuan Wang1, Fangju Lin2, Chienchih Wu1

1National Taiwan University Hospital, Taipei, Taiwan; 2National Taiwan University, Taipei, Taiwan

**Background:** Vancomycin (VAN) and piperacillin/tazobactam (TZP) have been widely used as empirical therapy for severe infections. Recently, several studies showed the increased risk of acute kidney injury (AKI) during concomitant use of VAN and TZP when compared to the risk during concomitant use of VAN and cefepime or meropenem. The mechanism of this nephrotoxicity is unclear. Teicoplanin (TEI) is another glycopeptide sharing similar spectrum and mechanism of action with VAN. Concurrent use of TEI and TZP is common; however, whether this combination also increases the risk of AKI is unknown. Therefore, this study aimed to evaluate the AKI risk of TEI/TZP, in comparison with the combination therapy of TEI and other anti-pseudomonal β lactams (APBs).

**Materials/methods:** This was a retrospective cohort study conducted in a medical centre in Taiwan. Adult patients admitted between Jun 1, 2013 and Dec 31, 2017 and treated with TEI based combination therapy (TEI/TZP or TEI/APB) were included. APBs contained cefoperazone/sulbactam, ceftazidime, cefepime, imipenem/cilastatin, meropenem and doripenem. Propensity score matching was used to balance demographic and confounding factors (age, gender, baseline creatinine, SOFA score, presence of shock and nephrotoxic agents). The primary endpoint was AKI during combination therapy, which was determined based on the Kidney Disease Improving Global Outcomes (KDIGO) criteria.

**Results:** There were 6,813 patients treated with TEI based combination therapy in the initial sample. After propensity score matching, 243 pairs (TEI/TZP:TEI/APB, 1:3 matched) were included for statistical analysis. Overall, the mean age was 66.3 years in the matched cohort, and 17.1% of patients had a shock. Use of nephrotoxic medications (45.7 vs. 48.7%) and the baseline eGFR (78.9 ± 31.3 vs. 81.1 ± 31.5 mL/min/1.73 m²) were similar in the two groups. The median dose of TEI was 10.7 mg/kg in both groups. There was no significant difference between the groups with respect to the risk of AKI (14.8% vs. 14.2%, P=0.815). However, mean time to AKI seemed shorter in the TEI/TZP group (4.6 vs. 6.3 days, P=0.039).

**Conclusions:** Co-administration of TEI and TZP is not associated with increased risk of AKI. This combination may provide a safe choice for patients who need broad-spectrum antibiotic therapy.

Abstract 4182

**Improved surveillance of Shiga toxin-producing Escherichia coli after implementation of whole genome sequencing at the Belgian National Reference Centre**

Florence Crombe¹, Diarie Soetens¹, Sylvie Leenen¹, Naïma Hammami², Bavo Verhaegen⁴, Sarah Denayer⁴, Denis Pierard*¹

¹Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, Belgium, ²Agence pour une Vie de Qualité, Département Santé, Direction Promotion de la Santé, Prévention et Surveillance des Maladies, Charleroi, Belgium, ³Agency for Care and Health, Infection Prevention and Control, Flemish Community, Gent, Belgium, ⁴Sciensano, Service of Foodborne Pathogens, National Reference Laboratory for STEC, Brussels, Belgium

**Abstract third-party references**: Part of this work was performed in the frame of the Belgian National Reference Centre for Shiga toxin-producing Escherichia coli, supported by the Ministry of Social Affairs through a fund within the National Health Insurance System.

**Background**: To date traditional typing methods are used at the Belgian National Reference Centre (NRC) for surveillance of Shiga toxin-producing Escherichia coli (STEC) infections. Yet, these methods are less discriminatory than whole-genome sequencing (WGS). The data obtained by WGS enables full characterisation of STEC isolates, which facilitates epidemiologic surveillance and facilitates data comparison in case of cross-border outbreak. In addition to traditional typing methods, we performed WGS on all STEC strains provided to the NRC in the first three quarters of 2019 in order to improve surveillance of STEC.

**Materials/methods**: Ninety-three STEC-positive faecal samples, provided on a voluntary basis by clinical laboratories to the Belgian NRC STEC between January and September 2019, were included. WGS was performed on all isolates by the Brussels Interuniversity Genomics High Throughput core (BRIGHTcore). Sequencing libraries were prepared using the KAPA Hyper Plus kit (Kapa Biosystems) and sequenced on Illumina NGS instruments. The sequencing data was analysed using the Escherichia/Shigella cgMLST typing scheme in EnteroBase.

**Results**: Overall, ten clusters of two to four cases were identified by WGS analysis. Only two of these could be identified based on traditional typing data complemented with epidemiological data. On top of this, four paediatric HUS cases could be related to two cross-border clusters, i.e. cgMLST HC5/351 79 and cgMLST HC5/65006. As the source of contamination of the latter cluster was known from EPIS inquiry UI-531, trace back investigations performed by the health inspection authorities could confirm this finding. In addition, in collaboration with the National Reference Laboratory for STEC, the probable food source of contamination of cgMLST HC5/196140 cluster could be identified based on WGS data only. Besides, one Belgian paediatric HUS case, that was identified and analysed abroad, whose WGS data was available in EnteroBase, could be linked to the national cgMLST HC5/194834 cluster.

**Conclusions**: The obtained results stress the utility of using WGS data for surveillance of STEC at the Belgian NRC. WGS data has firstly enabled clustering of cases that were not identified based on traditional typing data complemented with epidemiological data and secondly helped to identify the source of contamination.

Abstract 4183

**The intestinal carriage of colistin-resistant *Enterobacteriaceae* in a tertiary care hospital setting and whole genome sequence data analysis of *mcr-1* positive *Escherichia coli* isolates**

Jan Tkadlec1, Eva Smelikova1, Alžběta Baráková1, Marie Cabrniocha1, Gelbícová Tereza2, Renata Karpiskova2, Otakar Nyc1, Pavel Drevinek1, Marcela Krutova1

1Charles University 2nd Faculty of Medicine and Motol University Hospital, Department of Medical Microbiology, Prague, Czech Republic, 2Veterinary Research Institute, Department of Bacteriology, Brno, Czech Republic

**Background:** The emergence of plasmid-mediated colistin resistance is now a public health topic of the utmost importance because its spread could lead to outbreaks of virtually untreatable infections. We aimed to perform a sentinel testing survey to gather data on the prevalence and/or spread of *Enterobacteriaceae* resistant to colistin carrying *mcr*-genes.

**Materials/methods:** Between June 2018 and September 2019, rectal swabs or fecal samples from patients hospitalized in Motol University Hospital, Prague, Czech Republic were enriched in 5ml *Enterobacteriaceae* enrichment broth (Mossel) overnight and the enriched cultures were tested for the presence of *mcr-1* to -8 genes by multiplex qPCR assays. The enriched cultures were also inoculated onto selective agar Brilliance UTI Clarity agar (Oxoid) supplemented with colistin (3.5 mg/L). Bacterial colonies of *Enterobacteriaceae* with confirmed resistance to colistin by broth microdilution method (BMD) were retested for the presence of *mcr-1* to 8 genes. For *mcr* positive isolates the susceptibility to common antimicrobials were determined by BMD and the isolates were subjected to whole genome sequencing (WGS) using MiSeq (Illumina) and/or MinION (Nanopore) platforms. De novo assembly was performed using Geneious R10 software and data were analysed using online tools at the website: www.genomicepidemiology.org.

**Results:** In a 15-month period, 1,922 samples were investigated. The colistin resistant *Enterobacteriaceae* (MIC >2 mg/L) were recovered from 15.24% (n=293) of samples; *Klebsiella* spp. (n=129), *Escherichia coli* (n=84), *Enterobacter* spp. (n=49), *Citrobacter* spp. (n=22), *Salmonella* spp. (n=9). Four *E. coli* isolates (0.21%) were positive for the presence of the *mcr-1* gene. Other *mcr*-genes were not detected. The results of WGS analysis of the *mcr-1* positive isolates are summarized in Table 1.

**Conclusions:** To the best of our knowledge, this is the first study on the carriage of *mcr-1* to -8 genes in hospitalised patients in the Czech Republic. The Czech hospitalised patients can be colonized by colistin resistant *Enterobacteriaceae*, including strains carrying the *mcr-1* genes.

**Acknowledgment:** Supported by Ministry of Health of the Czech Republic, grant nr. NV18-09-00254.

Abstract 4185

Clonal spread of mcr-3-carrying multidrug-resistant ST34 Salmonella Typhimurium and its monophasic 1,4,[5],12:i:- from human globally

Liangxing Fang*, Ruanyang Sun1, Wenying Guo1, Jian Sun1, Xiao-Ping Liao1, Ya-Hong Liu1

1South China Agricultural University, Guangzhou, China

Background: Recently, the MDR ST34 S. Typhimurium (including its monophasic variant), has become a potential threat to public health due to its global emergence of mobile colistin resistance genes, including mcr-1 and mcr-3. However, to date, it is still blank on prevalence and transmission of mcr-3 in Salmonella in China. Thus, in the present study, a retrospective study was conducted to examine the emergence of the mcr-3 gene in Salmonella Typhimurium and 1,4,[5],12:i:- isolates from patients with diarrhea, and to reveal the mechanisms involved in transmission of mcr-3.

Materials/methods: A total of 582 Salmonella Typhimurium and 2299 Salmonella 1,4,[5],12:i:- strains were recovered from faecal samples of diarrhea patient from 28 general hospitals in Guangdong province during 2015-2017. All the Salmonella isolates were screened for mcr-3, submitted to WGS sequencing and conjugation experiment.

Results: Among the 2881 Salmonella isolates, 10 (0.35%) were mcr-3 positive, including 1 Salmonella Typhimurium and 9 Salmonella 1,4,[5],12:i:-. These 10 isolates were recovered from patients in 6 different hospitals located in four cities. Most of them were resistant to 8 antibiotics, including colistin, ampicillin, cefotaxime and ciprofloxacin. A phylogenetic tree based on the core genome revealed a close relationship between all of the 10 mcr-3 positive Salmonella isolates from this study and almost all of the 41 mcr-3-positive Salmonella isolates [37 from clinical human and 4 from swine from five countries] from GenBank except for three ones (SNPs ≤ 665), and in particular, some of them showed an extremely high degree of whole-genome sequence similarity to each other [38-99 SNPs]. WGS analysis revealed that all of the 51 mcr-3-positive Salmonella isolates harbored diverse ARGs, and of note, 35 of them including 10 ones from this study showed a similarity ARGs profile, including mcr-3-blaCTX-M-55-qnrS1. mcr-3 genes were successfully transferred to the recipient strain E. coli C600 among 6 of 10 mcr-3-positive Salmonella isolates, and Each transconjugants carried a single mcr-3-positive plasmid co-bearing blaCTX-M-55 (n=6) and qnrS1 (n=5) and assigned to ST3-IncC.

Conclusions: Our findings suggested clonal spread of MDR ST34 Salmonella lineage co-harboring mcr-3 with blaCTX-M-55 and qnrS1 globally.

**Vaginal microbiota in Japanese women undergoing infertility treatment**

Asami Matsumoto*1, Yuka Yamagishi2, Seiichiro Takahashi1, Yasutoshi Kuroki4, Ayaka Minemura4, Kentaro Oka1, Motomichi Takahashi1, Hiroshige Mikamo2

1Aichi Medical University, Aichi, Japan, 2Aichi Medical University Graduate School of Medicine, Aichi, Japan, 3Takahashi Ladies Clinic, Gifu, Japan, 4Miyarisan Pharmaceutical Co., Ltd., Saitama, Japan

**Background:** A healthy vaginal microbiota is typically dominated by *Lactobacillus* spp. Dysbiosis of the vaginal microbiota (VM) might be responsible for the bacterial vaginosis (BV) which causes sexually transmitted infections, low pregnancy rate, spontaneous abortion and preterm delivery. In late years it is suggested that dysbiosis of VM has been linked infertility, albeit the details do not become clear. There are few reports that analyzed comprehensively the VM of the infertility treatment patient for Japanese women. Therefore, in this study, we analyzed VM of Japanese women during infertility treatment to elucidate the association between infertility and VM.

**Materials/methods:** In February 2019, we collected the vaginal samples of 16 women during infertility treatment at Takahashi Ladies Clinic, Gifu, Japan for further assessments. Nugent score was calculated using vaginal discharges. VM was analyzed by 16S rRNA gene sequenced metagenomic analysis by Miseq (Illumina) platform. Simultaneously, we isolated vaginal lactobacilli by using selective medium.

**Results:** As a result of Nugent scoring, 9 patients were normal (score 0-3) and 4 patients were intermediate (score 4-6) whereas 3 patients were diagnosed as a BV (score 7-10). VM were clearly clustered into 2 groups. Seven patients were classified in cluster 1 and 9 patients were classified in cluster 2. Cluster 1 was characterized with *Lactobacillus* spp. dominant but cluster 2 was constituted by not only *Lactobacillus* spp. but also *Escherichia* spp., *Gardnerella* spp., *Bifidobacterium* spp. and *Streptococcus* spp. and a few other taxa. The mean Nugent score of cluster 1 was 1.7 (score 0-7) whereas that of cluster 2 was 4.1 (score 0-10). There was no significant difference of detection rate of live lactobacilli between cluster 1 and 2.

**Conclusions:** Our results showed that VM of Japanese women during infertility treatment were divided into 2 groups. Further, Nugent score was correlated with composition of VM. We are investigating the pregnancy and delivering rates to elucidate the association between these rates and composition of VM. Concurrently, we are identifying the species of vaginal lactobacilli because it is suggested that the risk of bacterial vaginosis varies according to a kind of *Lactobacillus* spp.

Abstract 4188

**Oxacillinase-48-like (OXA-48) carbapenemases along with New Delhi metallo-β-lactamase in a neonatal unit**

Sharmi Naha¹, Subhankar Mukherjee¹, Kirsty Sands², Pinaki Chattopadhyay³, Suchandra Mukherjee³, Sulagna Basu*¹

¹ICMR-National Institute of Cholera and Enteric Diseases, Kolkata, India, ²Cardiff University, School of Medicine, Cardiff, United Kingdom, ³Institute of Post-Graduate Medical Education And Research, Kolkata, India

**Background:** Emergence of oxacillinase-48-like (OXA-48) carbapenemase-producing Enterobacteriaceae is a critical health problem. Recently, reports of OXA-48-like carbapenemases are being reported in India more frequently than New Delhi Metallo-β-lactamase (NDM). The present study analyses the prevalence of OXA-48-like carbapenemases in Enterobacteriaceae isolated from the blood of septicemic neonates during 2013-2016, their transmissibility, association with sequence types and whole genome analysis.

**Materials/methods:** Identification, susceptibility test and genotypic characterization were carried out. Whole genome sequencing (WGS) was performed for isolates with OXA-48-like carbapenemases. Resistome, virulome, sequence type (ST), IS element, phage analysis, CRISPR, etc. were done. Transmissibility of this gene was evaluated by conjugation or electroporation.

**Results:** Six percent of isolates harboured OXA-48-like carbapenemases out of 195 Enterobacteriaceae isolated. All the isolates were extensively drug resistant but were susceptible to tigecycline and colistin. WGS analysis revealed two variants of OXA-48 gene viz. OXA-181 (67%) and OXA-232 (33%) among the isolates. *bla*<sub>OXA-181/232</sub> was found to be linked with Col plasmid. Association of OXA-181/232 was found with ST14, ST15, ST23, ST48, and ST231. Co-acquisition of *bla*<sub>OXA-48</sub> and *bla*<sub>NDM</sub> was found in five isolates (ST14 and ST2) along with other resistance determinants. OXA-181/232 was flanked by ∆IS<i>Ecp1</i> on upstream and ∆lysR & ∆ereA on downstream of it in accordance with isolates from other regions. Transfer of OXA-181/232 was not successful by conjugation. Presence of CRISPR array associated-cas3 gene along with different phage protein as well as intact phage was found in the genome of the isolates. Different virulence determinants were found in the genome which makes these isolates not only a successful pathogen but also a good colonizer. All the genomes were 85%-99% similar among themselves.

**Conclusions:** Prevalence of OXA-48-like carbapenemases is low in the unit, but association of this gene with other potent carbapenemases such as NDM-5 and in diverse STs is worrisome. The linkage of *bla*<sub>OXA-181/232</sub> with non-conjugative plasmid has probably restricted its spread. Proper surveillance and appropriate antibiotic strategy is required to keep the spread of these genes under check.

**Presenter email address:** supabasu@yahoo.co.in
Neutrophil extracellular traps and matrix metalloproteinases are increased in TB meningitis patients with contrast enhancement, ventricular dilatation and poor neurological outcome: findings from a paediatric cohort

Xuan Ying Poh*, Jia Mei Hong¹, Qing Hao Miow¹, Yu Wang¹, Pei Min Thong¹, Masako Fukushima³, Ke Juin Wong⁴, Tsin Wen Yeo⁵, Catherine Ong¹

¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, ²Tan Tock Seng Hospital, Singapore, Singapore, ³Tōkatsu Hospital, Nagareyama, Japan, ⁴Hospital Likas, Kota Kinabalu, Malaysia, ⁵National Neuroscience Institute, Singapore, Singapore, ⁶Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore

Background: Immunopathology in TB meningitis (TBM) patients is driven by extensive brain inflammation and tissue destruction and may be attributed to neutrophil extracellular traps (NETs) and matrix metalloproteinases (MMPs) which we sought to investigate.

Materials/methods: The cerebrospinal fluid (CSF) of 62 paediatric patients with TBM, bacterial meningitis (BM), viral meningitis (VM) and non-infectious causes (NI) were analysed for NETs by quantitative fluorometry of extracellular DNA and MMPs by Luminex assay. Glasgow Coma Scale (GCS) for children above 3 years old and Blantyre Coma Scale (BCS) for those below 3 years old were used to assess patients on admission. The CT or MRI brain of TBM patients were assessed for radiological abnormalities including contrast enhancement and ventricular dilatation by a neuroradiologist blinded to patient outcomes. Poor clinical outcome is defined as death or survival with severe neurological deficits, while good outcome is defined as full recovery or survival with mild neurological deficits.

Results: NETs were 7.2-fold higher in TBM than BM ($p < 0.01$) and 4.9-fold higher ($p < 0.05$) compared to NI. CSF concentrations of EMMPRIN (26.6-fold, $p < 0.01$), MMP-2 (8-fold, $p < 0.05$) and -9 (12.1-fold, $p < 0.05$) were significantly increased in TBM patients compared to BM patients. NETs showed a significant negative correlation with GCS ($r = -0.46$, $p < 0.05$) and BCS ($r = -0.3$, $p < 0.05$), indicating that patients with worse neurological condition have higher CSF NETs concentrations. TBM patients who showed radiological abnormalities have increased CSF concentrations of NETs (Fig. 1), as well as MMP-3, -7 and -10. TBM patients with poor clinical outcome have increased CSF concentrations of NETs (Fig. 1) and MMP-10 than TBM patients with good clinical outcome.

Conclusions: We showed that NETs are increased in TBM compared to BM and NI patients. Patients with abnormal radiological findings and poor clinical outcomes have higher NETs and MMPs than those without, suggesting that NETs and MMPs may prognosticate outcome in TBM.

Presenter email address: e0148993@u.nus.edu

Figure 1. Concentration of NETs in paediatric TBM patients in the presence or absence of abnormal radiological features and with poor or good clinical outcome. **, $p < 0.01$.  
Abstract 4199

Achieving sustained decolonisation of CPE in sinks

Gili Regev-Yochay*1,2, Gill Smollan1, Hanaa Jaber1, Carmit Cohen1, Ilana Tal1, Nani Pinas Zade1, Carmit Rubin1, Sharon Amit1, Eyal Zimlichman1,2, Nati Keller1,3

1Hospital, Sheba Medical Center, Ramat Gan, Israel, 2University, Tel Aviv University, Tel Aviv, Israel, 3University, Ariel University, Ariel, Israel

Background: The spread of carbapenemase-producing Enterobacteriaceae (CPE) is leading to a public health crisis. Recently, the role of the hospital water environment and particularly sink-traps has been recognized. This study tested seven technologies.

Materials/methods: The study was carried out during 2017-2019, at a large tertiary Medical Center (1600-bed). Following the discovery that many of the sink-traps were persistently contaminated with CPE, seven different technologies were studied in 9 departments. Persistently contaminated sink-traps were replaced either to PVC sink-trap or to one of the tested technologies and were sampled weekly. Sink sampling was performed via vigorous swabbing of the sink-trap surface or the internal part of the sink-outlets via sterile swabs. Chromagar KPC plates and Maldi-TOF were used to identify CPE. Carbapenemase genes were identified using Xpert Carba-R PCR (GeneXpert Cepheid). The studied technologies included: 1. Weekly acetic acid treatment, 2. weekly actizyme® treatment, 3. copper sink-traps, 4. nickel sink-traps, 5. specially designed “smart siphon” sink-traps, 6. Moveo® self-disinfecting siphon, and 7. the Sheba-Hamat self-disinfecting sink.

Results: A total of 130 sinks which were found to be constantly contaminated with CPE were replaced and one of 7 technologies were tested. A total of 3138 samples were taken.

<td>4 (33.3%)</td>
<td>1.3%</td>
</tr>
</tbody>
</table>

Conclusions: Only three technologies reduced the contamination rate of the sink-traps. Copper and nickel sink-traps were significantly better than regular PVC sink-traps, although most of them were eventually re-contaminated. However the Sheba-Hamat sinks were extremely better and only very rarely got re-contaminated.

Diagnostic performance and validation of two ready-to-use real-time PCR assays for the detection of *Plasmodium spp.* and the principal species capable to infect human

Cristina Escolar*1, Nieves Martínez Cameo1, Mª Pilar Hernández2, Pilar Egido2, Ana Milagro2, Antonio Rezusta2

1University of Zaragoza, Zaragoza, Spain, 2Hospital Universitario Miguel Servet, Zaragoza, Spain

**Background:** Malaria early diagnosis and treatment are crucial because of its high prevalence and mortality worldwide. Despite its limitations, identification under microscopy remains the diagnostic reference method. However, molecular methods have arisen as an available option. CerTest Biotec (Spain) has developed two real-time PCR products to detect and quantify *Plasmodium spp.* and identify the species *P. falciparum, P. vivax, P. ovale, P. malariae and P. knowlesi* in blood samples. Following, the performance and added benefits compared to clinical routine diagnosis were evaluated.

**Materials/methods:** This study performed the clinical evaluation of Viasure *Malaria* and Viasure *Malaria differentiation* real time PCR detection kits, both with internal control (IC) and extraction control (EC) variants, in comparison with routine techniques. Thus, 311 clinical samples of patients attended in Hospital Universitario Miguel Servet (Spain) and collected from July 2017 to July 2019 were used. Routine analysis was based on serological assay (Alere Binaxnow Malaria©), direct visualization under the microscope and two molecular assays RealStar Malaria PCR© (Altona) and FTD Malaria differentiation© (Fast-track diagnostics). This study was approved by the Clinical Research Ethics Committee of Aragon (PI19-381).

**Results:** A total of 226 eluates and 119 clinical samples were analysed using the product variants IC and EC, respectively. 64/226 and 35/119 samples were positive for *Plasmodium* spp. Among them, 2 samples were positive for *P. malariae*, 2 for *P. ovale*, 5 for *P. vivax* and 55 for *P. falciparum*. Comparison with routine molecular assays showed 100% overall agreement and sensitivity and specificity values of >99%. Comparison of the molecular assays with the ICT and microscopy techniques showed loss of 7.81% of the samples with ICT and 21.8% of false negatives with microscopy.

**Conclusions:** Evaluated products fulfill the criteria of accuracy, sensitivity and specificity. In addition, compared with the "reference" commercial assays, the obtained results were faster and more profitable. A highlight feature of Viasure products was that thanks to this lyophilized format, their manipulation was minimal, without intermediate mixtures, and was very useful for storage and transport at room temperature instead of using refrigerated containers and occupying place in the freezers of the hospital.

**Presenter email address:** cristinaesco87@gmail.com
Successful salvage therapy for mucormycosis with isavuconazole in paediatric patients: cases series

Liat Ashkenazi-Hoffnung1,2, Efi Bilavski1,2, Galiya Grisaru1,3, Efraim Sadot1,2, Itzhak Levy1,2, Salvador Fischer1,2, Elhanan Nahum1,2, Oded Scheuerman1,2

1 Schneider Children’s Medical Center of Israel, Petach-Tikva, Israel, 2 Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, 3 Dana Children’s Hospital, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Mucormycosis is a life-threatening fungal disease that occurs primarily in immunocompromised patients with hematological malignancies, but also in other patients such as those with diabetes mellitus or trauma. Isavuconazole is a new second-generation triazole with a favorable safety profile that has shown efficacy in the adult population for primary and salvage treatment of mucormycosis. However, data regarding its efficacy and long-term safety in the pediatric population are scarce.

Materials/methods: The demographic and clinical data of pediatric patients with mucormycosis who were treated with isavuconazole in 2017-2019 were collected. Children with histopathological evidence of the disease or growth on fungal cultures from a sterile body site were included.

Results: Four children of median age 10.5 years (range 7-14) met the study criteria. Two had rhino-orbital involvement and one each had cutaneous with deep tissue involvement or disseminated infection. Three had underlying hematological malignancies, and one had sustained major trauma. Two had concomitant infection with Aspergillus spp. Isavuconazole was used as salvage therapy in all: in three patients for refractory disease, and in one after intolerance to another anti-fungal drug. Following initiation of isavuconazole, alone or combined with other anti-fungal agents, complete clinical, radiological, and mycological responses were documented in all patients. The median treatment duration was 2.5 months (range 2-4), during which no isavuconazole-related adverse events were noted. Median follow-up time was 22 months (range 3-48). There were no cases of recurrent infection or mortality during follow-up.

Conclusions: Our limited clinical experience showed that isavuconazole was well-tolerated, safe, and efficacious as salvage therapy in pediatric patients with mucormycosis. The overall end-of-treatment complete response rate was 100%. Prospective clinical trials are needed to evaluate the safety and efficacy of isavuconazole in the pediatric population and its role as first-line treatment for mucormycosis.

Figure 1 – Chest and abdominal computed tomography scans of the patient with disseminated mucormycosis demonstrating necrosis and cavitary lesions of the left lower lobe of the lung, lesions in the liver, spleen and left kidney and infiltration of the colon and abdominal wall. Despite the extensive involvement, the patient had a complete recovery after initiation of isavuconazole salvage therapy.

Abstract 4208

Two-hours direct detection of *Mycobacterium tuberculosis* complex in clinical samples by molecular method based on real-time PCR

Cristina Escolar*1, Jessica Comín1, Ana Picó1,2,3, Mark Strunk2, Henar Alonso4, Sofia Samper2,3

1University of Zaragoza, Zaragoza, Spain, 2Instituto Aragonés de Ciencias de la Salud, Zaragoza, Spain, 3Centro de Investigación Biomedica en Red de Enfermedades Respiratorias, Instituto de Salud Carlos III, Zaragoza, Spain, 4Ministerio de Ciencia, Innovación y Universidades, Zaragoza, Spain

**Background:** Human tuberculosis (TB) continues to be a major cause of morbidity and mortality worldwide. One essential factor for controlling the spread of this disease is the ability to diagnose infection in its early stages. The gold standard in diagnosing still relies on clinical examination combined with direct microscopic examination of clinical samples and culture of bacteria. However, the culture can take up to 8 weeks and in 10-20% of cases, the bacillus is not successfully cultured. Delay in diagnosing a non-suspected TB case means that the patient is under a non-adequate treatment and therefore remains infectious for longer time. Tools for TB diagnosis changed substantially in the last decades thanks to the development of molecular methods. Here, we evaluate the Viasure *M. tuberculosis* complex real time PCR detection kit (CerTest Biotec, Spain) comparing with traditional methods used to diagnose *M. tuberculosis*.

**Materials/methods:** The study was performed using 67 DNAs from human clinical sputum samples (collected from 2005 to 2012 in Aragon, Spain) diagnosed as positive or negative for *M. tuberculosis*. These samples included different DNA from complex genotypes from lineages 1 to 5 and DNAs belonging to the lineage of strains that affect animals. To analyse the specificity of the test, five different nontuberculous mycobacteria were included in the analysis. The test was performed according to the instruction manual. The run was performed using ViiA™ 7 Real-Time PCR System (Applied biosystems).

**Results:** All samples were correctly detected. 60/65 were detected as *M. tuberculosis* complex isolates and 5/65 were detected as negative for *M. tuberculosis* complex isolates. This real-time PCR achieved a sensitivity and specificity, positive predicted value and negative predicted value of 100% in identifying *M. tuberculosis* complex isolates.

**Conclusions:** Obtained results were optimal in sensitivity and specificity, therefore the use of this product is recommended. In addition to this, the kit is presented in ready to use lyophilized format, reducing time-consuming in the lab and avoiding possible contaminations. Moreover, the stabilized format permits to transport and storage the kit at room temperature, which we considered an important advantage.

Abstract 4209

**Validation of new anti-staphylococcal compounds within a group of potential sortase A inhibitors**

Olena Moshynets*1, Galyna Volynets1, Taras Baranovskyi2, Georgiana Nitulescu3, Margina Denisa3, Anca Ungurianu3, Volodymyr Bdzhola1, George Mihai Nitulescu1, Sergiy Yarmoluk1

1Institute of Molecular Biology and Genetics of the NAS of Ukraine, Kiev, Ukraine, 2Shupyk National Medical Academy of Postgraduate Education, Kiev, Ukraine, 3Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

**Background:** Staphylococcus spp. is a causative agent of many hospital and community-acquired infections with the tendency to develop resistance to the beta-lactam antibiotics. Alternative glycopeptide and oxazolidinone antibiotics are losing their effectiveness due to the resistance spread. Thus, the search of novel effective targets and their corresponding inhibitors to develop principally new antibiotics is of urgent need. Nowadays, sortase A is considered as a promising molecular target for the development of antistaphylococcal agents. Sortase A is a membrane-bound transpeptidase which catalyzes the transfer and immobilization of essential virulence factors to the surface of the microorganism. Inhibitors of sortase A affect virulence and biofilm formation, therefore decreasing selective pressure leading to the development of antibiotic resistance.

**Materials/methods:** Phenotypic screening, rational drug design.

**Results:** The phenotypic screening of the library containing 15 512 compounds from different chemical classes against methicillin resistant S. aureus ATCC43300 was performed. As a result, 250 compounds with anti-staphylococcal activity demonstrating the MIC values in the range from 0.25 mg/L to 32 mg/L were identified. The molecular docking of these compounds into active site of this enzyme using the DOCK program was performed to identify which compounds potentially can inhibit staphylococcal sortase A. There were 10 compounds selected for the following in vitro tests based on the results of molecular docking calculations and visual inspection of the best-scored complexes. A recombinant Sortase A protein has been obtained and the in vitro enzymatic activity inhibition assay where sortase-inhibiting activity has been identified for the selected inhibitors was performed. In parallel, the biofilm growth inhibition assay was conducted for S. aureus ATCC25923 and a number of methicillin-resistant and vancomycin-resistant staphylococci isolated from Ukrainian patients. The anti-staphylococcal biofilm-inhibition activity for a number of selected compounds has been confirmed.

**Conclusions:** A number of new compounds with anti-staphylococcal activity has been identified.

Abstract 4211

Investigation of carbapenem- and tigecycline-resistant Klebsiella pneumoniae in a Greek hospital

Angeliki Mavroidi*1, Eleftheria Palla1, Durania Kordanouli1, Sofia Likousi1, Konstantina Zourla1, Eleni Merkouri1, Evangelia D. Platsouka1

1Konstantopouleion Potission General Hospital of N. Ionia, Department of Microbiology, Athens, Greece

Background: Tigecycline is one of the last resource antimicrobial agents for the treatment of infections caused by carbapenem-resistant K. pneumoniae (CR-Kp). The purpose of the present study was the investigation of tigecycline resistance (TIG-R) among CR-Kp in a Greek tertiary hospital during January 2017-December 2018.

Materials/methods: Identification and antibiotic susceptibility testing of the isolates was performed by the Vitek®2 Compact 15 (bioMérieux) and interpreted according to the CLSI, 2018 criteria. Minimum inhibitory concentrations (MICs) of tigecycline and colistin were determined by the gradient Liofilchem® MIC Test Strip, S.R.L. and the MIC Strip Colistin, MERLIN, Diagnostika, GmbH broth microdilution methods, respectively, and interpreted according to the EUCAST criteria. The carbapenemase content of CR+TIG-R Kp was determined by the immunochromatographic method NG-Test® CARBA. PCR amplification of the ramR gene associated with tigecycline resistance was carried out. Genotyping of selected isolates was performed by MLST, as described previously.

Results: During the study period, a total of 618 Kp isolates were recovered at the Department of Microbiology. Of the 618 Kp, 267 (43.2%) were characterized as CR, 177 (28.7%) as colistin-resistant (COL-R) and 143 (23.6%) as TIG-R. From 2017 to 2018, the rates of isolation of TIG-R Kp and CR+TIG-R Kp increased from 1.3% to 31.8% and from 3.2% to 12.8%, respectively. All CR+TIG-R Kp (52 out of 618, 8.4%) Kp were extensively-drug resistant (XDR), whereas 18 of them were COL-R, and characterized as pandrug-resistant. Among the 52 CR+TIG-R Kp, 21 KPC, 21 VIM, 5 NDM, 3 OXA-48+NDM, 1 KPC+VIM, 1 OXA-48 producers were identified. MICs of tigecycline were >4mg/L for 17 VIM, 4 KPC, 1 NDM and 1 OXA-48+NDM producers. Screening for the ramR gene has revealed that 19/19 VIM, 6/20 KPC, 2/5 NDM, and 1 KPC+VIM producers were positive, whereas no PCR products were obtained for the remaining isolates. Genotyping of bloodstream KPC and VIM producers has revealed that they belonged to MLST STs 258 and 147, respectively.

Conclusions: The spread of CR+TIG-R XDR Kp in settings with high rates of carbapenem and colistin resistance limits the therapeutic options for infections caused by this pathogen.

Abstract 4213

Role of the Ixodidae (Acari: Ixodidae) ticks, mosquitoes, and horse-flies in the transmission of vector-borne diseases in Belarus

Volha Kniazeva*1, Yuliya Pogockaya1, Yuliya Leshchanka1, Anatoliy Krasko1

1The Republican Research and Practical Center for Epidemiology and Microbiology, Minsk, Belarus

Background: Ticks and mosquitoes are the most significant worldwide arthropods of the medical importance. They may transmit a broad variety of pathogens causing diseases to humans and animals. Vector-borne diseases are spread in Belarus and have raising occurrence, mainly due to climatic and environmental changes and the increase of the mobility of people and animals.

Materials/methods: 359 Ixodidae (Acari: Ixodidae) ticks (Ixodes ricinus, Dermacentor reticulatus), 34 horse-flies (Tabanus bovinus) and 1006 mosquitoes (Aedes, Culex) were collected in natural foci of the Republic of Belarus during the period of their activity from May to September 2019. 272 ticks were analyzed individually by real-time PCR amplification for the presence of Borrelia spp., TBEV, Rickettsia spp., Anaplasma phagocytophilum and Ehrlichia muris. Furthermore, part of ticks, mosquitoes and horse-flies were divided by 15-20 in pools and tested for West Nile virus (WNV) by real-time PCR.

Results: The high prevalence of DNA of Borrelia spp. in ticks from all administrative regions of Republic of Belarus (38.97%). The highest content of the pathogen 69.44% was registered in Vitebsk region. Mean Rickettsia spp. prevalence was 29.78% with active foci in Vitebsk (52.78%) and Grodno (38.89%) regions. Less spread pathogens were TBEV (15.81%), Anaplasma phagocytophilum (19.49%), Ehrlichia muris (14.71%). Comparison current data with the prior year showed increase of Borrelia spp. and TBE infected ticks (38.97% in year 2019 vs 35.7% in year 2018 and 15.81% in year 2019 vs 8.8% in year 2018 respectively). The analysis of 57 pools (857) mosquitoes collected at the end of May 2019 didn’t demonstrate the presence of WNV whereas mosquitoes and ticks collected in July conformed the locative circulation (2 from 11 pools of the mosquitoes and 5 from 44 pools of ticks were positive for WNV).

Conclusions: The study of vectors and pathogens they may transmit is an essential measure for prevention and control vector-borne diseases worldwide. The ticks - inhabitants of Belarus carry and can transmit Borrelia spp., TBEV, Rickettsia spp., Anaplasma phagocytophilum, Ehrlichia muris and WNV. The locative circulation of WNV infection in Belarus was conformed and, along with other zoonoses, needs additional attention from healthcare authorities.

Abstract 4216

Checkpoint Plus Freiburg: performance of an on-site integrated, low-threshold sexual transmitted diseases/HIV counselling and treatment service in Germany

Matthias Müller*,1,2; Susanne Usadel2; Stefan Zimmermann3; Ulrike Hoffmeister2; Adreas Fahrhöfer3; Winfried Kern2; Siegbert Rieg1

1Medical Center, Faculty of Medicine, University of Freiburg, Division of Infectious Diseases, Department of Medicine II, Freiburg, Germany, 2Department of Infection Medicine, Medical Care Center, MVZ Clotten, Freiburg, Germany, 3AIDS-Hilfe Freiburg, Freiburg, Germany

Background: In Germany, number and rates of new sexual transmitted infections (STI) are steadily increasing and incidence of HIV infections remains high. In order to address this issue, Checkpoint Plus (CP+) was established in January 2018 offering low threshold access for STI/HIV counselling and testing, with integration of psychosocial and medical services including on-site treatment. Objective of this study was to analyse the performance of CP+.

Results: Over the study period, an increasing number of client contacts was registered resulting in a total of 1093 contacts (Figure 1). Clients’ median age was 29.5 year (range: 18.5-62.7), 69.5% were male, 29.0% female, 0.1% trans*woman and 1.1% not binary. Clients’ sexual orientation was heterosexual (48.8%), homosexual men (37.5%) and bisexual (10.8%). Clients were from Germany (74.9%), other European countries (12.1%), and non-European countries (13%). More than one third of clients received their first STI/HIV counselling in CP+. STI/HIV screening resulted in the diagnosis of infection with N. gonorrhoeae (GO, n=11), C. trachomatis (CT, n=18), T. pallidum (n=4), and HIV (n=1). Additionally, 115 patients with HIV pre-exposure prophylaxis (PrEP) were followed for a total of 36.6 patient years. Incidence of asymptomatic STI at PrEP-initiation was n=3 for GO and n=6 for CT, whereas during follow-up under PrEP n=7 cases of GO, n=7 of CT and n=2 of Syphilis were diagnosed.

Conclusions: Substantially more non-HIV-STIs were detected, emphasizing the need for regular and low threshold screening services for bacterial STIs. The concept of CP+ may facilitate access to STI/HIV counselling and testing for a wide spectrum of people and may prove to be an important contribution to the efforts to reduce STI and HIV incidence in Germany.

Figure 1: Number of client contacts per quarter between February 19, 2018 and September 09, 2019 at Checkpoint Plus Freiburg - an on-site integrated, low threshold sexual transmitted diseases/HIV counselling and treatment service in Germany

Molecular epidemiology of varicella zoster virus in Pitié-Salpêtrière University Hospital, Paris, France

Melinda Cheminet¹, Sonia Burrel², David Boutolleau*¹

¹Pitié-Salpêtrière University Hospital, National Reference Center for Herpesviruses, Paris, France

Background: Varicella-zoster virus (VZV) nomenclature currently recognizes 6 established (major) clades, termed 1 to 6, and 3 provisional clades, termed VII to IX. VZV genotyping strategies rely on evaluating a panel of single nucleotide polymorphisms (SNPs) across the different open reading frames (ORFs) of the viral genome. A geographical segregation of VZV clades has been shown, with clades 1, 3 and 6 predominating in Europe, clade 5 in Africa, clade 2 in Japan and East-Asia, and clade 4 in Asia. However, this regional distribution of VZV clades is dependent on increase of immigration and travels, implementation of varicella vaccine, and recombination events. The surveillance of VZV epidemiology is therefore necessary. The aim of this work was the molecular characterization of VZV isolated from patients in our University Hospital.

Materials/methods: Fifty-three consecutive patients (31 males, 22 females, median age 49 years [1 - 87]) experiencing varicella or zoster during were included during the year 2018. Most of them originated from Europe (24; 45.3%) and Africa (14; 26.4%), and 22 (41.5%) were immunocompromised. Clinical samples consisted in 49 mucocutaneous swabs, 2 whole bloods and 2 cerebrospinal fluids. VZV genotyping was based on the identification of targeted SNPs in ORF1, 22 and 50.

Results: VZV clade 1 was detected in 16 patients (30.2%), clade 3 in 16 patients (30.2%), clade 4 in 2 patients (3.8%), clade 5 in 17 patients (32.0%), and clade 6 in 2 patients (3.8%). The distribution of VZV clades did not differ according to gender, VZV-associated pathology (varicella or zoster), or immunosuppression. Patients with varicella due to clade 5 were significantly younger than those with varicella due to other clades (14.5 versus 43 years; p=0.004).

Conclusions: This study revealed similar proportions of VZV clades 1, 3, and 5 among patients. Moreover, varicella patients with VZV clade 5 were younger than others, indicating that VZV clade 5 infects the population earlier during childhood. This result may suggest that the African VZV clade 5 is able to spread more efficiently in the population than the historically circulating European VZV clades 1 and 3.

Abstract 4221

Microbiome analysis of faecal microbiota transplantation via lyophilised capsules for recurrent *Clostridioides difficile* infection

Laura Villar Gomara*, Silvia Noemi Vazquez Cuesta1, Nuria Lozano1, Maria Olmedo Samperio1, Sara Rodriguez-Fernandez1, Martha Kestler Hernandez1, Luis Alcalá1, Mercedes Marín1, Patricia Muñoz1, Emilio Bouza1, Elena Reigadas Ramirez2

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

**Background:** Fecal microbiota transplantation (FMT) has proven to be effective in the treatment of recurrent *Clostridioides difficile* infection (R-CDI). However, use of FMT in clinical practice continues to be very restricted, probably due to the methods of administration (colonoscopy, enema or via nasojejunal tube). Few studies have been performed with capsules containing lyophilized fecal matter. Our group has previously reported success in the treatment of R-CDI with FMT via lyophilized capsules. The objective of this study was to characterize the microbiome changes associated with the use of FMT with a novel approach using lyophilized capsules.

**Materials/methods:** Fecal samples from patients with recurrent CDI who underwent FMT via lyophilized capsules (single dose of 4-5 capsules) were collected during Jan 2018-Jul 2019. FMT recipients' stools were collected before and after the procedure. Also stool specimens from the donors and the capsule’s lyophilized content were collected. All samples underwent microbiome analysis, briefly, the hypervariable V4 region of the 16s rRNA gene was amplified, sequencing (2 × 250) was performed on a Miseq platform (Illumina; California, USA) according to standard protocols. Mothur’s bioinformatic pipeline was followed for data analysis.

**Results:** Microbiome samples (n= 57 samples) were available for 33/36 patients, nine different FMT capsule batches from 8 different donors and their original stool samples were analyzed. Bray-Curtis based non-metric multidimensional scaling (NMDS) analysis indicated that donor’s microbiomes and final lyophilized FMT capsule product were alike, whereas Pre-FMT recipients’ samples were dissimilar to both. NMDS analysis showed that recipients’ microbiome converged toward donors’ microbiome profile and capsule microbiome after FMT treatment (Figure). Before FMT (n=33), patients’ microbiomes were dominated by Gammaproteobacteria (24.3%), Bacilli (23.2%) and Negativicutes (19.0%), with low abundance of Clostridia (5.4%). After FMT (n=24), there was an increase in the number of OTUS and alpha diversity, Clostridia increased (41%), together with a decrease in Gammaproteobacteria (15.4%) and Bacilli (6.2%).

**Conclusions:** Our results show that lyophilized FMT product closely resembles donor’s microbiome. Treatment of R-CDI with FMT lyophilized capsules was associated with restorative microbiome changes that resemble donor microbiome. This form of administration will allow FMT to be more widely used.

**Presenter email address:** laura.villar@msn.com
Risk factors for colonisation with carbapenemase-resistant Acinetobacter baumanii in hospital

Marianna Meschiari*, Kaleci Shaniko, Silvia Selmi, Mario Sarti, Gabriella Orlando, Marianna Menozzi, Cristina Mussini

1Infectious Disease Clinic, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy, 2Clinical and experimental medicine, Research Group on Health Sciences Data Analysis University of Modena and Reggio Emilia, Modena, Italy, 3Clinical Microbiology Laboratory, University Hospital of Modena, Modena, Italy

Background: Despite surveillance cultures could predict the development of Carbapenemase-resistant Acinetobacter baumanii (CRAB) infections, rectal active surveillance role in CRAB spread control remains debated. Our aim is to identify the main risk factors associated with CRAB intra-hospital rectal colonisation in endemic acute care facilities in order to drive targeted screening strategies.

Materials/methods: A matched case-control study was conducted at the Azienda Ospedaliera Universitaria of Modena from January 2017 to December 2018. According with the hospital screening policy, all underwent rectal swab during the study period on admission and weekly. A patient was defined as a case if he met all of the following criteria: isolation of a CRAB strain from rectal swab screening, hospital stay ≥ 4 days at time of screening and no isolation of CRAB from any sample in the previous 6 months. Controls were selected among patients with a negative rectal swab for CRAB on the same day as the matched case. Two controls were individually matched to each case by age, date of screening and ward at the time of screening.

Results: Forty-five patients colonized by CRAB were considered and 90 controls: 37.8% from internal medicine, 37.8% from geriatric, 8.9% from surgical and 15.6% from intensive care units. The multivariate logistic regression adjusted for the length of hospital stay (odds ratio [OR]=1.03; 95% confidence interval [CI], 1.01-1.05, p-value=0.002) show that the use of indwelling devices (OR=10.15; 95% CI, 2.27-45.39), the urinary catheter (OR=4.96; 95% CI, 1.52-16.19), the tracheostomy (OR=40.01; 95% CI, 4.05-395.10), the McCabe Score (OR=5.45; 95% CI, 1.87-15.89), and the use of carbapenems (OR=5.39; 95% CI, 1.14-25.44) were the main risk factors for colonization. Analysing the single department: in geriatric, the use of hospital devices and the McCabe Score increases the risk by 10 and 15 times, respectively, while in internal medicine disabilities or bedridden with medical devices. In ICU antibiotic exposure (carbapenems and cephalosporines) were significantly associated with outcome.

Conclusions: Antibiotic therapy associated with disabilities and medical devices play a crucial role for CRAB rectal colonisation. These findings could allow an early identification of CRAB asymptomatic carriers and prevent infection transmissions in endemic setting.

Abstract 4227

Colistin-resistant Enterobacteriaceae in Belgian broiler and pig farms

Sien De Koster1, Moniek Ringenier2, Christine Lammens1, Marjolein Kluytmans - Van Den Bergh1,4, Jan A. J. W. Kluytmans4,5, Jeroen Dewulf2, Herman Goossens1

1University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious Diseases Institute, Antwerp, Belgium, 2Ghent University, Veterinary Epidemiology Unit, Department of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Merelbeke, Belgium, 3Amphia Hospital, Department of Infection Control, Breda, Netherlands, 4Utrecht University, Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands, 5Amphia Hospital, Microvida Laboratory for Microbiology, Breda, Netherlands

Abstract third-party references: i-4-1-Health Study Group

Background: Colistin is a last-resort antibiotic for the treatment of multidrug-resistant Gram-negative bacterial infections. The antibiotic has been used in veterinary medicine, especially in pigs to treat post-weaning diarrhoea caused by Escherichia coli. This study determined the burden of colistin-resistant Enterobacteriaceae (ColR-E) in Belgian broiler and pig farms

Materials/methods: As part of the i-4-1 Health project, a total of 400 broiler and 400 pig fecal samples were collected from broiler (n=15) and sow farms (n=15) in Belgium between September 2017 and April 2018. A random-stratified design was used to collect twenty to thirty samples per farm (FecalSwab, Copan Italy). The presence of non-intrinsically ColR-E was investigated using selective culturing and colistin MIC testing using broth microdilution (epidemiological cut-off: 2 mg/L). To quantify colistin use, treatment incidence was calculated in accordance with Timmerman et al. (2006). A selection of ColR-E (E. coli n=14, Klebsiella pneumoniae n=15, Klebsiella oxytoca n=2, Enterobacter cloacae n=2) was sequenced (Illumina MiSeq) to determine genotype-phenotype correlations. Core genome multilocus sequence typing (cgMLST) was used to determine clonal relatedness.

Results: The percentage of samples positive for ColR-E was higher in pigs (22%) compared to broilers (0.75%) (Figure 1A). A positive correlation was found between within-farm colistin use and presence of resistance (Kendall’s tau: 0.52, p<0.01). Of all resistant strains, 67% were E. coli exhibiting MIC between 4 and 16 mg/L. Resistance was also detected in K. pneumoniae (28%), K. oxytoca (2%) and E. cloacae complex (3%) exhibiting MIC of 4 to >64 mg/L. Plasmid-mediated resistance genes were absent in 9/33 of the ColR-E, suggesting that other mechanisms are involved. Based on PROVEAN scores, we show mutations that possibly influence colistin susceptibility. Disruption of mgrB by stop codon or insertion sequence was predominant in K. pneumoniae (Figure 1B). K. pneumoniae ST101, an emerging clone associated with increased mortality rates in humans, was detected with high-level colistin resistance in pigs.

Conclusions: This study revealed that ColR-E are found in Belgian farms. The presence of high-level colistin-resistant strains, like K. pneumoniae ST101, in pig farms is a potential public health threat.
Figure 1: Colistin resistance in broiler and pig farms. Prevalence of ColR-E and colistin use in Belgian farms (A). Phenotype-genotype correlations in colistin-resistant *Escherichia coli* (B) and *Klebsiella pneumoniae* (C). Branch numbers represent allelic differences based on cgMLST (scheme based on 3437 alleles in *E. coli* and 4785 alleles in *K. pneumoniae*). * stop codon, empty spaces are unknown resistance mechanisms and sequence types.

High prevalence of sexually-transmitted infections among at-risk HIV-positive patients

Kuan-Yin Lin1, Hsin-Yun Sun2, Yu-Chung Chuang2, Un In Wu2, Wen-Chun Liu2, Tai-Fen Lee2*, Sui-Yuan Chang2, Yi-Jing Chen3, Chien-Ching Hung2

1National Taiwan University Hospital Jin-Shan Branch, New Taipei, Taiwan, 2National Taiwan University Hospital, Taipei, Taiwan, 3National Taiwan University, Taipei, Taiwan

Background: Sexually transmitted infections (STIs) have been continuously increasing after the introduction of biomedical HIV interventions. This study aimed to investigate STI prevalence and associated factors among at-risk HIV-positive patients in a country implementing treatment as prevention and pre-exposure prophylaxis for HIV.

Materials/methods: From May to November 2019, multiplex real-time PCR detecting Chlamydia trachomatis (CT), Neisseria gonorrhoeae (NG), and Trichomonas vaginalis (TV) were prospectively performed in urine and rectal specimens collected from HIV-positive patients with a history of STIs or symptoms suggestive of STIs. Patients confirmed to have acquired STIs were treated according to treatment guidelines. Tests of cure were taken at least 3 weeks after completion of treatment.

Results: During the 6-month study period, 405 HIV-positive patients (99.0% being men who have sex with men (MSM)) with a median age of 37 years were included for analysis. The overall prevalence of CT and/or NG positivity was 27.7% (112/405), including 23.5% for CT, 10.6% for NG, and 0.2% for TV. While 96.4% (108/112) of STIs were detected from rectal swab specimens, only 16.1% (18/112) were detected from urine specimens. The clinical factors associated with acquisition of CT or NG were younger age (per 1-year decrease, adjusted odds ratio [AOR], 1.04; 95% confidence interval [CI], 1.01 - 1.08), hepatitis B virus infection (AOR, 2.42; 95% CI, 1.24-4.75), recent hepatitis C virus infection (AOR, 2.98; 95% CI, 1.35-6.58), recent rapid plasma reagin titer ≥8 (AOR, 2.11; 95% CI, 1.11 -4.04), and HIV plasma viral load >20 copies/mL (AOR, 2.33; 95% CI, 1.27 -4.34). The behavioral risk factors were lower income (AOR, 2.27; 95%CI, 1.08-4.76), oral sex in 6 months (AOR, 2.13; 95% CI, 1.01 -4.49), and inconsistent condom use (AOR, 3.03; 95% CI, 1.47-6.23). Among 60 patients completing test-of-cure visits, 56 patients (93.3%) had achieved microbiological clearance.

Conclusions: Our findings strongly support STI screening at sites of exposure for HIV-positive MSM. Patients infected with viral hepatitis and syphilis frequently were coinfected with bacterial STIs.

Abstract 4230

**Acute bacterial prostatitis due to *Escherichia coli*: clinical characteristics and outcomes in patients treated with or without β-lactam antibiotics: a cohort study**

Laura Marina Gisbert*, Helena Monzon1, Beatriz Dietl1, Tere Moreno-López1, Lucía Boix-Palop1, Mariona Xercavins Valls2, Esther Calbo Sebastian1

1Hospital Universitari Mutua de Terrassa, Terrassa (Barcelona), Spain. 2CatLab, Viladecavalls (Barcelona), Spain

**Background:** Acute bacterial prostatitis (ABP) is a common urinary tract infection (UTI) with an incidence between 10-25%. Despite its frequency, it is poorly characterized in the literature. Our objective was to describe clinical characteristics of ABP due to *Escherichia coli* in a cohort of consecutive adult men comparing outcomes in patients treated with or without β-lactam antibiotics.

**Materials/methods:** Observational retrospective study. Setting: acute-care teaching hospital. Period: January-2010 to June-2019. Cases: consecutive ≥18 year-old males, admitted to the Emergency Room of an acute-care teaching hospital, with a clinical syndrome compatible with ABP and a urine culture with a significant growth of *Escherichia coli*. Study variables: demographics, management, complications and clinical outcomes. Treatment groups: patients treated with any β-lactam antibiotic (Group 1) and patients treated with either a quinolone or Cotrimoxazole (Group 2).

**Results:** One hundred and twenty-seven patients were included. Demographics and clinical characteristics are summarized in Table 1:

*Median, interquartile interval (IQI). ^1Within the previous year. ^2In the previous 30 days.

Fifty-three patients (42%) were treated with β-lactams and 58 (46%) with either quinolones or Cotrimoxazole. Clinical cure at end of therapy (EoT) was 83% in Group 1 and 93% in Group 2 (p=0.1); reinfection and relapse rates -within 90 days after EoT- were 2% in Group 1 versus 3% in Group 2 (p=1) and 9% in Group 1 versus 0% in Group 2 (p=0.02) respectively.

**Conclusions:** ABP due to *Escherichia coli* affects middle-aged males with previous urinary tract conditions. Relapse was more frequent among patients that received directed therapy with a beta-lactam.

Abstract 4231

**Nano chitosan effect on Plasmodium falciparum in vitro**

Fatemeh Tabatabaie*, Taher Elmi1, Zahra Zamani2

1Department of Parasitology and Mycology, Faculty of Medicine, Iran University of Medical Sciences, Tehran, Iran, 2Biochemistry Department, Pasteur Institute of Iran, Pasteur Avenue, Tehran, Iran

**Background:** The inevitable side effects, inefficiencies and also emerging the resistances of current drugs in the treatment of Malaria have led researchers around the world to think about finding new treatments for Malaria. The aim of this work was preparation of chitosan nanoparticle delivered from fungi for treatment Malaria disease.

**Materials/methods:** In this research prepared chitosan nanoparticle from *Penicillium* fungi and investigated the effect of nano chitosan on protozoan of *Plasmodium falciparum*. Nano-chitosan was prepared from chitosan extracted from *Penicillium* fungi, and characterized by FTIR, DLS and SEM. Then chitosan nanoparticle toxicity on PC12 cells and the effect of hemolysis on erythrocytes were evaluated by MTT and spectroscopy, respectively. The *P. falciparum* protozoan was collected then species confirmed using PCR-RFLP method, and cultured in RPMI1640 medium. Finally, the antiparasitic effect of nano chitosan was evaluated by the addition of chitosan nanoparticle to the protozoan culture medium.

**Results:** Prepared nano chitosan (100 nm), demonstrated no toxic effect on PC12 cells and not hemolytic effect on human erythrocytes. The highest antiparasitic activity was observed at 50 μg/mL concentration. This concentration of nanoparticles was preventing 59.5% from the growth of *P. falciparum* in the culture medium.

**Conclusions:** The synthesized nano chitosan, due to the low side effects and acceptable effect on this protozoa, could be considered as an antiparasitic nanodrug that needs further systematic study.

Adenovirus-associated epidemic keratoconjunctivitis outbreak in a tertiary hospital
Elisenda Miro*1, Margarita Del Cuerpo1, Carla Berengua1, Pilar Marin1, Jose Ignacio Vela2, Virginia Pomar3, Nuria Rabella1

1Hospital de la Santa Creu i Sant Pau, Microbiology Dpt., Barcelona, Spain, 2Hospital de la Santa Creu i Sant Pau, Ophthalmology Department, Barcelona, Spain, 3Hospital de la Santa Creu i Sant Pau, Infectious Diseases Unit, Barcelona, Spain

Background: Human adenoviruses (HAdVs) are one of the main causative agents of conjunctivitis. Epidemic keratoconjunctivitis, which usually occurs as an outbreak, is predominantly caused by HAdV-D genotypes. In this work, we describe an outbreak of keratoconjunctivitis caused by HAdV-D8 in patients attending the Ophthalmology Department of Santa Creu i Sant Pau Hospital (Barcelona) from May to September 2018.

Materials/methods: Exudates from the bottom of the conjunctival sac (one per patient) were processed for antigen detection by Light Diagnostics™ Adenovirus Antibody (Merck) direct immunofluorescence and inoculating four cell culture lines. The HAdV genotype was obtained after PCR and sequencing. The sequences were analysed by BioNumerics 7.6 software and uploaded to https://www.rivm.nl/mpf/typingtool/enterovirus/.

Results: On August 14, 2018, the Ophthalmology Department notified the Infectious Diseases Unit of a suspected outbreak of keratoconjunctivitis after an unexpected increase in diagnosis. Epidemiological data (Figure 1) show that the first case was diagnosed on July 20, with the highest number of cases (8) being detected on August 6. A total of 14 cases were diagnosed before the Infectious Diseases Unit was alerted. After August 14, one sample from each keratoconjunctivitis patient was sent to the microbiology laboratory to be characterised. A total of 22 samples were collected, and among these, 13 samples were positive for HAdV and were all genotyped as HAdV-D8. A possible focus of this outbreak was the slit lamp shared by all patients. No case was detected among the clinical staff.

Conclusions: Nosocomial outbreaks caused by HAdV-D8 are rarely described because keratoconjunctivitis can be diagnosed and treated without having to characterize the causative agent. However, the importance of describing the etiologic agent should be emphasized, as it enables more efficient epidemiological surveillance.

Figure 1. Epidemiological surveillance of the 36 patients with keratoconjunctivitis.

Detection of low-level vanB-type vancomycin-resistant Enterococcus faecium with agar screen methods

Stefanie Van Koeveringe1, Katherine Loens1,2, Ingrid Mermans1, Hilde Jansens1, Herman Goossens1,2, Veerle Matheeussen*1,2

1University Hospital Antwerp, National Reference Centre for Enterococci, Edegem, Belgium, 2University of Antwerp, Department of Medical Microbiology, Vaccine & Infectious Disease Institute (VAXINFECTIO), Antwerpen, Belgium

Abstract third-party references: Supported by the Belgian Ministry of Social affairs through a fund within the Health Insurance System.

Background: VanB-containing E. faecium show variable phenotypic resistance to vancomycin (MIC: 4-1,024 mg/L). The detection of the currently circulating low-MIC ST117 vancomycin resistant E. faecium strain is challenging as its resistance is poorly induced by vancomycin. EUCAST has recently published warnings in order to improve detection of low-MIC VRE with gradient strip tests. However, EUCAST’s advice for breakpoint agar methods has remained unchanged so far. We aimed to study the performance of an home-made and commercial agar screen method for detection of low-MIC VRE.

Materials/methods: Twenty-five low-level vancomycin resistant E. faecium strains, submitted at the Belgian National Reference Centre for Enterococci in 2017 and 2018, were selected. All strains were vanB positive (via in-house real-time PCR) and belonged to ST117 (via conventional PCR followed by Sanger sequencing or whole genome sequencing using Nextera XT (2x250bp), MiSeq [Illumina]). MIC values were obtained by gradient strip testing and ranged from 2-4 mg/L. Ten µl of 0.5 McFarland bacterial suspension of the selected strains was applied on an home-made vancomycin screen agar (VancoScreen, 6 mg/L vancomycin) and on the VREselectTM Medium (Bio-Rad, 8 mg/l vancomycin). Growth for both agars was evaluated after 24h and 48h incubation at 35°C. Ten vancomycin susceptible E. faecium strains were used as control.

Results: After 24h incubation no growth was observed for 5/25 (20%) (4x MIC 4 mg/L and 1x MIC 2 mg/L) E. faecium strains on VREselectTM and 3/25 (12%) (2x MIC 4 mg/L and 1x MIC 2 mg/L) E. faecium strains on VancoScreen. Extending the incubation time to 48h resulted in growth of all strains on both media. For one strain with an MIC of 2 mg/L only one colony was detected on the VancoScreen both after 24 and 48h incubation. None of the vancomycin susceptible E. faecium strain grew on the vancomycin screen agars after 48h incubation.

Conclusions: Detection of low-level VRE E. faecium isolates with MIC levels of ≤4 mg/l is possible with agar screen methods. However, exposure of these strains to vancomycin should be extended to 48h to fully induce their resistance (instead of 24h according to EUCAST). Furthermore, any growth should be taken into account.

Abstract 4239

**Economic burden of recurrent *Clostridium difficile* infection (rCDI) in adult patients admitted in Spanish hospitals: multi-centre, retrospective, observational study**

Emilio Bouza*1, Javier Cobo Reinoso2, María Jesús Rodriguez Hernandez3, Miguel Salavert4, Juan P. Horcajada5, Jose Antonio Iribarren Loyarte6, Engels Obi7, Virginia Lozano8, Stefano Maratia8, Maribel Cuesta9, Estefany Uria9, Enric Limón10

1Hospital General Universitario Gregorio Marañón, Madrid, Spain, 2Hospital Universitario Ramón y Cajal, Madrid, Spain, 3Hospital Virgen del Rocío, Sevilla, Spain, 4Hospital Universitario y Politécnico de La Fe, Valencia, Spain, 5Hospital del Mar, Barcelona, Spain, 6Hospital Universitario Donostia, San Sebastian, Spain, 7Merck & Co., Inc., Kenilworth, New Jersey, United States, 8Merck Sharp & Dohme, Madrid, Spain, 9Oblikue Consulting, S.L, Barcelona, Spain, 10VINCat Coordinator Center, Catalan Health Department, University of Barcelona, Barcelona, Spain

**Abstract third-party references:** Merck & Co., Inc., Kenilworth, NJ, USA

**Background:** *Clostridium difficile* infection (CDI) is the most common gastrointestinal nosocomial infection and the main cause of diarrhea in hospitalized patients in Spain. CDI is associated with an increased hospital stay and mortality and a high probability of readmission, resulting in an increased use of healthcare resources and greater costs for the National Healthcare System (NHS). The aim of the study was to estimate the economic burden of rCDI in the Spanish setting.

**Materials/methods:** Multicenter, retrospective, observational study. Hospitalized patients with at least one diagnostically-confirmed episode (primary or secondary diagnosis) of rCDI between January 2010 and May 2018 were retrospectively reviewed in 6 Spanish centers. Healthcare resources included were hospital length of stay (emergency room, general ward, isolation unit and intensive care unit) as well as tests and treatments. If the primary admission diagnosis was rCDI the entire hospital stay was considered attributable to rCDI. If the primary admission diagnosis was any other than rCDI and the secondary diagnosis was rCDI, the additional hospital stay was estimated as the difference with respect to an episode without rCDI (control group). Cases and controls were matched [1:1] using the propensity score matching. Control episodes were collected in the Spanish National Hospital Discharge Database. Total costs were calculated by multiplying the natural resource units used by the corresponding unit cost (€ 2019).

**Results:** 282 rCDI episodes were reviewed (188 as primary diagnosis). 187 (66.31%) were patients aged ≥65 years and 163 (57.80%) were female. Median rCDI hospital length of stay was 10.00 days per episode [IQR: 6.00-17.00], obtaining similar results for both, primary [10.00 (IQR: 6.00-16.00)] and secondary diagnosis [10.00 (IQR: 4.00-20.00)]. Total mean cost per rCDI episode was 10,877€ (CI 95%: 9,498€-12,777€), of which 47% was due to the need of single patient room for contact precautions.

**Conclusions:** The economic burden of rCDI managed in the hospital setting is 10,877€ per episode. At national level, rCDI episodes represent an estimated expenditure between 13.9 -21.3 million euros per year. Results suggest that healthcare resources use needed to treat rCDI and related costs have a high economic impact on the Spanish NHS.

Abstract 4241

**Investigation of a vancomycin-resistant enterococci outbreak at a cardiothoracic-surgery department: new insights from next-generation sequencing**

Miriam Van Den Nest*1, Magda Diab-Elschahawi2, Gisela Dechat1, Andreea Bilc1, Luigi Segagni Lusignani1, Elisabeth Presterl1

1Medical University of Vienna, University Department of Hospital Hygiene and Infection Control, Wien, Austria

**Background:** Vancomycin-resistance among Enterococcus faecium has been increasing rapidly over the past years. At the same time, infections and deaths due to Vancomycin-resistant Enterococci (VRE) have risen, and VRE outbreaks have been reported worldwide. Both, colonization and infection with VRE are associated with higher mortality, prolonged stays in hospitals and higher costs. Appropriate infection control measures are still debatable, though. In May 2019, we observed an increased rate of VRE at the cardiothoracic-surgery department of an academic hospital; here we present preliminary results from our investigation.

**Materials/methods:** An epidemiologic investigation and molecular typing, using Next-Generation Sequencing (NGS), was conducted. In order to contain the possible outbreak, immediate infection control measures, including isolation of patients, reinforcement of hand hygiene as well as intensified cleaning and disinfection, were taken.

**Results:** From May 2019 onwards, we started the outbreak investigation installing intensified personal infection control measures, environmental cleaning and disinfection, as well as universal rectal screening at the cardiothoracic-surgery department. A VRE prevalence of 6.6% (26/394) was detected. In total, from December 2018 until November 2019, VRE were found in 38 patients. Our rigorous infection control measures seemed to be effective, as only five new cases appeared since July. By using NGS, to date, we identified six distinct VRE clusters including 31 patients; five patients appeared as independent strains. The strains belonged to the multilocus sequence types ST78, ST80, ST117 and ST787. According to our extensive epidemiologic investigation, 27 patients, who fitted to one of the genetic clusters, had had contact with each other at the wards, i.e. were admitted to the same ward at the same time.

**Conclusions:** Using NGS, we were able to cluster VRE strains genetically. In connection with our epidemiologic investigation, these results suggest inward transmissions for many of the VRE cases, while others might be a result of selection through antibiotic administration. In any case, well developed hygiene practices and infection control measures were crucial in avoiding the spread of VRE.

Abstract 4242

Validation of Simplexa HSV 1 & 2 Direct and Simplexa VZV Direct kits for herpes simplex virus and varicella zoster virus detection from low-volume cerebrospinal fluid samples

Sonia Burrel1, Olivier Bomme1, Odile Roger1, Jean-Claude Piot1, Bruno Le Labousse1, Nathalie Hamm1, Elodie Chaicaud1, David Boutolleau*1

1Pitié-Salpêtrière University Hospital, National Reference Center for Herpesviruses, Paris, France

Background: Herpes simplex virus 1 and 2 (HSV-1 and HSV-2) and varicella-zoster virus (VZV) are major causes of infectious meningoencephalitis. Therefore, rapid and accurate detection of viral genomes in cerebrospinal fluid (CSF) is mandatory for management and treatment of patients. However, low-volume CSF may be available for molecular testing. We evaluated the sample-to-result real-time PCR assays Simplexa™ HSV 1 & 2 Direct and Simplexa™ VZV Direct on LIAISON® MDX platform with the use of 25µL of sample volume, instead of 50µL as recommended by the manufacturer DiaSorin Molecular

Materials/methods: Cycle threshold (Ct) values obtained from 50µL and 25µL of sample volume tested were compared for 60 HSV-positive and 60 VZV-positive different samples: 35 CSFs from patients, 37 CSFs spiked with different quantities of ATCC HSV-1, HSV-2, or VZV strains, and 48 QCMD samples from previous years. Reproducibility using 25µL of sample was evaluated by intra- and inter-assay comparisons

Results: All 120 positive samples were detected using either 50µL or 25µL, leading to a concordance of 100%. No PCR inhibition was observed. The difference of Ct values obtained with the 2 volumes tested for each sample (ΔCt [50-25]) was below or equal to 1.0 for 102 (85%) samples and ranged from 1.1 to 1.6 for 18 (15%) samples. Mean ΔCt [50-25] values were -0.1, -0.1, and -0.2 for HSV-1 HSV-2, and VZV, respectively. Coefficients of variation (CVs) obtained for intra-assay variability (Simplexa™ Positive Controls tested 8 times in a single Direct Amplification Disk) were 3%, 3%, and 1.9% for HSV-1, HSV-2, and VZV, respectively. CVs for inter-assay variability (Simplexa™ Positive Controls tested 10 consecutive times once a week) were 1.7%, 1.0%, and 1.3% for HSV-1, HSV-2, and VZV, respectively.

Conclusions: The results obtained in this study allow the validation of the performances of Simplexa™ HSV 1 & 2 Direct kit and Simplexa™ VZV Direct kit for the detection of HSV-1, HSV-2, and VZV genomes in CSF with the use of 25µL of sample with no loss of sensitivity. This validated protocol will be useful to perform molecular tests with low-volume CSFs, especially for pediatric patients

Da Procida-ADU-San Giovanni e Ruggi D’Aragona.University of Salerno, Naples, Italy, 14Hepatology Unit, Cardarelli Hospital Naples, Naples, Italy, 15Department of Medical, Surgical, Neurological, Metabolic, and Geriatric Sciences, University of Campania "L. Vanvitelli, Naples, Italy

**Background:** DAA-regimens are associated with failure in about 5% of cases, due with the emergence of resistance associated substitutions [RASs] within the viral quasispecies. This study characterized the virological patterns in genotype not-1 patients failing IFN-free regimens and evaluated the efficacy of re-treatment.

**Methods:** 75 HCV patients with failure to IFN-free regimen observed at the laboratory of infectious diseases of University of Campania, Naples. Sanger sequencing of NS3, NS5A and NS5B was performed at failure by home-made protocols.

**Results:** Patients enrolled were mainly males (80%), median age 58 years [range 31-86]. HCV RNA, IU/ml median value was 4.77 x 10e5 IU/ml [range: {1.3 x 10e3 IU/ml – 3.8 x 10e8 IU/ml}], 62.6% of patients had a diagnosis of cirrhosis. 26 patients were HCV genotype 2a/2c, 44 were genotype 3 and 5 were genotype 4.

The prevalence of RASs in NS5A region were more frequently detected in genotype 4 (80%) and genotype 3 (61,3 %) than in genotype 2a/2c (38,5%). RAS in the NS5B region were identified only in genotype 3 (18,1%) and genotype 2a/2c (3,8%). Out of the 75 patients enrolled, 35 [46,6 %] patients were re-treated; 84% were relapse, 4% breakthrough and 12% non-responder at retreatment.

The 18 patients re-treated with genotype 3 less frequently (77,7%) showed an SVR than the 11 patients with genotype 2 (84,6%). 60% of patients with genotype 2, 50% with genotype 3 and 60% with genotype 4 without SVR show RASs.

SVR was more frequent in patients HCV genotype 2 treated with the latest DAAs regimen [91% vs 9%, p=0.0001]; also, for patients with HCV genotype 3 treated with the latest generation DAAs [50% vs 27,8 %] SVR was more frequent.

All HCV genotype 4 patient failed at retreatment.

**Conclusions:** The prevalence of RASs was high in our population. Failed patients have at least one RASs in one HCV region. The latest DAA regimen more frequently obtained SVR despite previous regimen for HCV genotype 2 and 3.

HCV genotype 4 remains a difficult-to-treat genotype. Patients with Resistance-Guided Therapy more frequently obtain SVR.

NS3, NS5A and NS5B sequencing seems mandatory in the choice of re-treatment DAAs.

Abstract 4245

Investigation of linezolid resistance mechanisms of *Staphylococcus epidermidis* isolates collected in Gauteng, South Africa

Karen L. Addison¹, Kathy-Anne Strydom², Ebrahim Hoosien², Yenga John Bolukaoto¹, Marleen Kock¹, Marthie M. Ehlers*¹

¹University of Pretoria, Pretoria, South Africa; ²Ampath Laboratories, Pretoria, South Africa

**Background:** *Staphylococcus epidermidis* are Gram-positive bacteria known to cause infections in the compromised host. Linezolid is a treatment option in *S. epidermidis* infections; however, linezolid resistance mechanisms are becoming more prevalent. Linezolid resistance is due to chromosomally- and plasmid-mediated mechanisms such as 23S rRNA gene mutations and acquisition of the chloramphenicol-florfenicol resistance (*cfr*) gene, respectively. This study identified these mechanisms of linezolid resistance in *S. epidermidis* isolates obtained from private hospitals in Gauteng, South Africa.

**Materials/methods:** *Staphylococcus epidermidis* (n=27) cultured from blood using the BACT/ALERT® 3D system (bioMérieux, France) were collected from 2016 to 2018. Inclusion criteria were *S. epidermidis* isolates that tested linezolid resistant using the VITEK® 2 instrument (bioMérieux, France) according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST) guidelines. Isolates were identified using matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectrometry (MS) and speciation was confirmed using multiplex polymerase chain reaction (M-PCR) assays. Linezolid minimum inhibitory concentration (MIC) was determined using ETEST® (bioMérieux, France). A singleplex polymerase chain reaction (PCR) assay was used to detect the *cfr* gene. Pulsed-field gel electrophoresis (PFGE) was performed to determine genetic relatedness. Seven representative *S. epidermidis* isolates were selected for whole-genome sequencing (WGS).

**Results:** The PCR assays confirmed identification of the *S. epidermidis* isolates. The *cfr* gene was detected in eight (29.6%) of the 27 *S. epidermidis* isolates. The ETEST® (bioMérieux, France) MIC values ranged between 8 µg/mL and > 256 µg/mL. The PFGE showed genetic relatedness among the isolates that clustered into one major cluster, four minor clusters and five singletons across nine different hospitals. The *S. epidermidis* sequence types (ST)s found were ST23 (57.1%, n=4/7), ST2 (28.6%, n=2/7) and ST22 (14.3%, n=1/7). Mutations of the 23S rRNA gene were found at positions C2190T (ST23, ST2 and ST22 isolates), C2561T (one ST23 isolate) and G2603T (ST23 and ST22 isolates).

**Conclusions:** Isolates containing a combination of 23S rRNA gene mutations and the *cfr* gene showed higher linezolid resistant MIC values than isolates with only one of these resistance mechanisms. Therefore, the spread of linezolid resistant isolates indicates the need for judicious use of linezolid and effective infection control measures.

Abstracts 2020

Abstract 4246

**Epidemiology of respiratory colonisations and infections caused by *Aspergillus* and non-*Aspergillus* moulds in lung transplant patients**

Marion Helary¹, Cendrine Godet¹, Gilles Jebrak¹, Sandrine Houze¹, Hervé Mal¹, Christine Bonnal*¹

¹Bichat-Claude Bernard Hospital, Paris, France

**Background:** Molds are frequently isolated from pulmonary samples of lung transplant patients but few data are available on the burden of this colonization during the first post-transplantation period. The aim of our study was to describe the colonization of a cohort of lung transplant patients during this early post-transplantation period.

**Materials/methods:** All the patients who had undergone lung transplantation in 2017-2018 in our hospital were followed from their transplantation until August 2019, 31th. Pulmonary samples with mold positive cultures were analyzed. Clinical and radiological data were collected to classify the patients as colonized or infected following standard definitions (EORTC/MSG).

**Results:** Ninety-seven patients (44 in 2017 and 53 in 2018, mean age 55+/−11 years) were included: 66/97 (68%) bi-pulmonary transplanted, with mainly emphysema (31/97 [32%]) and fibrosis (41/97 [42%]) as underlying diseases. The mean delay between transplantation and the first positive culture of a respiratory sample with molds was 1.9 +/- 2.6 months. During the survey, 77 patients have had at least one positive culture with molds (81%): 75 colonizations (often with a mix of *Aspergillus* spp and other molds [55/75]) and 3 aspergillosis infections. Two hundred and fifty-four strains were isolated: 138 *Aspergillus* spp (mainly *A. fumigatus* [62] and *A. niger* [33]), and 116 other molds (mainly *Penicillium* spp [61, no *P. marneffei*], and zygomycetes [11]). There was no difference between mono- and bi-pulmonary transplanted patients. Eighteen patients died during the survey (18%), including 1 aspergillosis infection and 9 colonizations.

**Conclusions:** In our cohort, a majority of lung transplant patients were colonized during the early period after their transplantation. The colonization often associated *Aspergillus* spp and other molds, mainly *Penicillium* spp. This rise the question of the potential pathogenicity of these fungi: infections with *Penicillium* spp [other than *P. marneffei*] have already been described¹ and they are known for their inflammatory effects in the lung². Further studies are needed to evaluate the real impact of these colonizations with *Penicillium* spp. alone or associated with *Aspergillus* spp. or other molds in lung transplantation, and the impact of prophylactic antifungal treatments.

Abstract 4250

Healthcare associated infections and outcomes: changes between 2013 and 2018 in Turkey

1 University of Health Science, Istanbul, Turkey, 2 University of Kocaeli, Kocaeli, Turkey, 3 Marmara University, Istanbul, Turkey, 4 Kartal Koşuyolu Research and Training Hospital, Istanbul, Turkey, 5 University of Health Science, Bursa, Turkey, 6 Trakya University, Edirne, Turkey, 7 Ummaniyeh Research and Training Hospital, Istanbul, Turkey, 8 Ankara Research and Training Hospital, Ankara, Turkey, 9 Gaziosmanpaşa Taksim Research and Training Hospital, Istanbul, Turkey, 10 Baskent University, Ankara, Turkey, 11 Kütahya University of Health Science Katip Çelebi Research and Training Hospital, Kütahya, Turkey, 12 Batman State Hospital, Batman, Turkey, 13 Istanbul University, Istanbul, Turkey, 14 University of Health science, Afyon, Turkey, 15 Ankara University, Ankara, Turkey, 16 Ankara University, Ankara, Turkey, 17 Ankara State Hospital, Ankara, Turkey, 18 Istituto University, Istanbul, Turkey, 19 Hitit University, Corum, Turkey, 20 Erzincan Binali Yıldırım University, Erzincan, Turkey, 21 University of Health Science Samsun Research and Training Hospital, Samsun, Turkey, 22 Koc University, Istanbul, Turkey, 23 Bozok University, Yozgat, Turkey, 24 Florans Nightingale Hospital, Istanbul, Turkey

Background: We described the change in the epidemiology of healthcare associated infections (HAI), resistance and predictors of fatality.

Materials/methods: This retrospective multi-centric study included 25 hospitals from different geographic regions of Turkey for evaluation of the fatality. All patients with HAI in these centres in 2015 and 2018 were enrolled to the study. The diagnosis of HAIs was based on the criteria of the Centers for Disease Control and Prevention (CDC). Identification of the organisms was conducted using whichever automated system was used routinely at each centre (VITEK 2, Biome`rieux, Marcy l’Etoile, France; Phoenix, BD, Franklin Lakes, NJ, USA). Antibiotic susceptibilities were tested by disc diffusion or minimum inhibitory concentration tests according to the guidelines of the Clinical and Laboratory Standards Institute (CLSI), resistance was defined according to CLSI criteria.

Results: In total 9100 cases with HAI were fatal (41%). A total of 4539 patients in 2015 were compared with 4586 patients in 2018. There was no difference in fatality rate between two years. Blood-stream infection (BSI) was the most common (40%) infection, followed by pneumonia (33%), surgical-site infections (SSI, 23%), urinary-tract infection (UTI, 18%), gastrointestinal infections (GI, 3%) and central nervous system infections (CNS, 1%). Although BSI and SSI were significantly higher in 2018, the percentages of patients with pneumonia were lower in 2018 (Table 1). The highest rate of fatality was detected among the patients with pneumonia (57%). The fatality rates of infections were 46% in BSI, 35% in UTI, 34% in GI, 20% in MS and 14% in SSI. Klebsiella spp. was the most common (20%) causative pathogen. The resistance against carbapenem and colistin among Acinetobacter spp, Pseudomonas spp. and E. coli was significantly higher in 2018. The highest rate of fatality was detected among the patients with Acinetobacter spp (52-63%), fatality rates were similar between years (2015-2018). Among Gram-positive organisms, the most common ones were Enterococcus spp (8%), S.aureus (6%) and Coagulase-negative staphilococcus (6%).

Conclusions: Resistant Gram negative agents are the leading problem in infection control practice of Turkey. Proportion of Acinetobacter spp. decreased, but the proportion of Pseudomonas spp. increased.

Evaluation of the FILMARRAY pneumonia plus panel for rapid diagnosis of hospital-acquired pneumonia

Lise Cremet*1, Marwan Bouras1, Benjamin Gaborit1, Elise Persyn1, Valery-Pierre Riche1, Bertrand Rozec1, Karim Lakhal1, Antoine Roquilly1, Sophie Gibaud1

1CHU Nantes, Nantes, France

Background: Early appropriate antimicrobial therapy reduce the risk of pneumonia-related morbidity and mortality in critical care patients. Nevertheless, current culture methods take at least 48 hours to obtain antimicrobial susceptibility results. The new FilmArray® Pneumonia plus Panel (FAPP) offers advantage to rapidly detect and quantify in a single test, 18 bacteria, 9 virus, and 7 antibiotic resistance genes. This test was compared to conventional bacterial culture in 85 patients suspected of having hospital-acquired pneumonia (HAP).

Materials/methods: 207 respiratory samples from 85 patients [64 bronchoalveolar lavages (BALDs) and 74 endotracheal aspirates (ETADS) obtained at the time of HAP diagnosis, and 69 ETA obtained 2-3 days later (ETATT)], were analyzed in parallel by routine microbiology testing and FAPP at the laboratory of the Nantes University Hospital. Results of FAPP were not reported to clinicians. Routine microbiology testing were analyzed independently of FAPP.

Results: 60/85 (70.59%) patients had a positive result for at least one bacterial pathogen at the time of diagnosis by culture [43/64 (67.19%) BALDs and 46/74 (62.16%) ETADS], compared to 71/85 (83.53%) for FAPP [50/64 (78.13%) BALDs and 59/74 (79.33%) ETADS]. Among 53 patients with paired BALDs and ETADS, 77.36% had the same result for both samples with conventional method, compared to 66.04% for FAPP. Among positive samples, polybacterial results were obtained for 23/43 (53.49%) BALDs, 19/46 (41.30%) ETADS, and 7/30 (23.33%) ETATT by culture vs 30/50 (60.00%) BALDs, 37/59 (62.71%) ETADS, and 32/49 (65.31%) ETATT for FAPP. Haemophilus influenzae, the most frequent species detected by FAPP (33 patients at diagnosis), was not always identified in culture (24 patients at diagnosis). A carbapenemase and/or an ESBL were detected with both methods in 7 patients.

Conclusions: Overall, FAPP detected the main bacterial respiratory pathogens with greater sensitivity than culture. The concordance between both methods was higher for BAL, less contaminated with microbial flora. In case of polymicrobial specimen, FAPP facilitated the detection of bacterial pathogens. Implementing this strategy on BAL should improve and accelerate clinical decision and isolation care. We are currently measuring the extent to which FAPP results would have modified antimicrobial prescription and costs of care.

Differentiate diagnosis active TB infection and latent TB infection by using Interferon-\(\gamma\) released from CD8+ T cell and HBHA antigen

Yueyun Ma*1, Jinhua Tang2

1Xijing Hospital, the Air Force Medical University, Xi’an, China, 2Xijing Hospital, The Air Force Medical University, Xi’an, China

Background: There is about 1/3 of the world population infected with Mycobacterium tuberculosis (MTB). Among them, about 90-95% got latent infections, and only 5-10% of people have diseases. Interferon-\(\gamma\) release assay (IGRA) can be used to identify MTB infection, but it cannot differentiate active tuberculosis (ATB) and latent TB infection (LTBI). Because QuantiFERON-TB Gold Plus (QFT-Plus) can detect Interferon-\(\gamma\) released from CD8+ T cell in most ATB patients, and HBHA is highly expressed in latent TB, we would like to evaluate the potential differential diagnostic value between LTBI and ATB groups.

Materials/methods: 108 healthy people and 30 ATB patients were tested by QFT-Plus, and their demographic characteristics were analyzed. Meanwhile, flow cytometry was used to analyze the relationships between the QFT-Plus TB2-TB1 and the distribution of peripheral blood T lymphocyte subsets in ATB patients with positive culture results. Finally, 34 volunteers with positive QFT-Plus results were selected as LTBI group, 30 ATB patients with bacteriology confirmed as ATB group, the QFT-Plus newly added antigen and its potential differential diagnostic value between LTBI and ATB groups was evaluated by using the receiver operating curve (ROC). At the same time, 22 LTBI and 40 ATB patients were tested by using IGRA with HBHA antigen. Its potential differential diagnostic value between LTBI and ATB groups was evaluated by using ROC.

Results: In patients with ATB, TB2-TB1 was positively correlated with the proportion of CD8+ T cells in peripheral blood T lymphocytes \(r = 0.586, P = 0.004\), negatively correlated with the proportion of CD4+ T cells \(r = -0.511, P = 0.015\) and the ratio of CD4/CD8 \(r = -0.520, P = 0.013\). TB2-TB1 and HBHA has potential value for differentiating LTBI and ATB with AUC=0.771 [95%CI = 0.653-0.889] and AUC=0.886 [95%CI = 0.791-0.982]. When the cut-off value of TB2-TB1 is 0.305 IU/mL, its sensitivity and specificity for ATB are 66.7% and 79.4%. When the cut-off value of HBHA is 22.37 pg/mL, its sensitivity and specificity for LTBI are 86.4% and 82.5%.

Conclusions: Both of QFT-Plus and HBHA have the potential diagnostic value to identify ATB and LTBI.

Abstract 4255

Evaluation of the Allplex H. pylori and ClariR Assay PCR kit on gastric biopsies
Quentin Jehanne¹², Lucie Benejat¹, Francis Megraud¹², Emilie Bessède¹², Philippe Lehours*¹²
¹Chu Bordeaux Pellegrin, CNR Campylobacters-Helicobacters, Bordeaux, France, ²Université Bordeaux, INSERM U1053, Bordeaux, France

Background: The diagnosis of *Helicobacter pylori* infection can be made by PCR in gastric biopsies. The objective of this study was to evaluate retrospectively the performance of the Allplex™ *H. pylori* & ClariR Assay PCR kit (Seegene).

Materials/methods: A collection of 180 DNAs extracted from gastric biopsies was used in this study: 90 DNAs from *H. pylori*-negative patients and 90 from *H. pylori*-positive patients (10 culture-NEG/PCR-POS and 80 culture-POS/PCR-POS) (38 *H. pylori* wild-type [WT], and 52 *H. pylori* mutated). The average age of these patients was 48.3 years (+/- 18.6 years) with a sex ratio of 0.72. Allplex™ *H. pylori* PCR was performed on a CFX96™ real-time PCR System and analyzed using the Seegene Viewer software. The real-time PCR used as reference was our in-house *H. pylori* PCR (Oleastro M et al. J Clin Microbiol 2003) and discrepant results were tested by the Amplidiag PCR *H. pylori* kit (Mobidiag).

Results: The performances of Allplex™ *H. pylori* PCR are shown on the table. Regarding the detection of *H. pylori* in the 90 expected negative samples, 10 late amplifications were obtained (Ct >39). 7 of these 10 samples were also positive using the Amplidiag PCR *H. pylori* kit and were therefore considered a true positives.

data in %; PPV: positive predictive value; NPV: negative predictive value

Conclusions: The Allplex™ *H. pylori* PCR kit has excellent performances and can be integrated into the armamentarium of diagnostic tests for *H. pylori* infection. This kit has the advantage of differentiating the main mutations (A2142G, A2143G and A2142C) associated with macrolide resistance.

Abstract 4256

Stopping exposing rifampicin-resistant *Mycobacterium tuberculosis* to further rifampicin may lead to reversion to wildtype, preventing the evolution of compensating mutations

Philip Fowler*1

1Experimental Medicine, NDM, University of Oxford, Oxford, United Kingdom

Abstract third-party references: On behalf of the CRyPTIC consortium

**Background:** Rifampicin is one of four drugs in the standard first-line regime for treating tuberculosis. Resistance arises primarily through mutations in the *rpoB* gene, notably Ser450Leu which interferes with rifampicin binding. This mutation has been shown *in vitro* to confer a fitness cost which can be compensated by mutations in the adjoining *rpoC* gene.

**Materials/methods:** 10,000 clinical tuberculosis samples from the Comprehensive Resistance Prediction for Tuberculosis: an International Consortium (CRyPTIC) project were analysed. Each sample has (i) whole genome sequencing data, (ii) rifampicin minimum inhibitory concentrations (MICs), and (iii) granular growth data. The last two were measured using 96-well broth microdilution plates with the MICs measured independently by laboratory scientist, computer software and citizen scientists.

**Results:** Rifampicin-resistant strains with no known compensatory mutations in *rpoC* grow significantly slower (19.2 ± 0.4%, 95% CI) than rifampicin-susceptible strains (20.6 ± 0.3%). Rifampicin-resistant strains that do contain an *rpoC* compensatory mutation grow significantly better (23.1 ± 0.5%). The magnitude of compensation depends on the precise mutation, with several mutations growing markedly better on the microtitre plate than wildtype (e.g. V483A 25.8 ± 1.3%, I491V 24.6 ± 1.0%). This is consistent with these mutations also being fitter *in vivo*. In addition, multiple genetic signatures of reversion to wildtype at Ser450 were present (1.3% of samples with a mutation at position 450 in *rpoB* had ≥2 base changes in the codon). Crucially, these two effects, compensation and reversion, were mutually exclusive.

**Conclusions:** The slower growth of rifampicin-resistant strains collected by CRyPTIC can be explained, in part, by the known fitness cost of the *rpoB* Ser450Leu mutation. This effect can be mitigated by an increasingly large list of mutations in the *rpoC* gene, some of which grow faster than wildtype. The reversion signatures can be explained if removing rifampicin prior to any compensatory mutation arising can lead to a reversion to susceptibility. Alternatively, continuing to expose *M. tuberculosis* to rifampicin once resistance has arisen can lead to strains that grow faster than wild-type *in vitro*, potentially "locking in" rifampicin resistance.

Burkholderia spp. and Gram-negative non-fermenters in cystic fibrosis patients in Belgium: 2012-2018
Fedoua Echahidi1, Charlotte Peeters2, Evelien De Canck2, Ingrid Wybo1, Denis Pierard*1, Peter Vandamme2
1Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Department of Microbiology and infection control, National Reference Centre for Burkholderia cepacia complex, Brussels, Belgium, 2Universiteit Gent, Laboratorium voor Microbiologie–Faculteit Wetenschappen, Ghent, Belgium

Background: Burkholderia cepacia complex (BCC) bacteria are human pathogens, especially infecting cystic fibrosis (CF) patients as well as hospitalized immunocompromised patients. CF patients are also infected by other Gram negative non-fermenters (GNNF). These pathogens cause frequent and recurrent infective exacerbations in CF patients that can lead to premature death. As national reference centre (NRC) of Belgium, our main purpose is the surveillance of BCC and GNNF (except Pseudomonas aeruginosa and Acinetobacter) mainly in CF patients. The current work is a survey of BCC-GNNF data from 2012 to 2018.

Materials/methods: Each year, we receive BCC and GNNF isolates from each colonized patient. The isolates are quickly identified by MALDI TOF MS (Bruker) and genotyped by Random Amplification of Polymorphic DNA. The identification and genotyping are then confirmed by sequence analysis and by MLST respectively.

Results: From 2012 to 2018 we received 788 BCC-GNNF isolates from 673 patients. A total of 183 BCC and other Burkholderia spp. were received; 59% were Burkholderia multivorans, followed by Burkholderia vietnamiensis (16%) and Burkholderia cenocepacia (12%). A total of 605 GNNF were received, 49% of which were Achromobacter spp., followed by Stenotrophomonas maltophilia (23%) and other species at lower proportions.

Of the 294 Achromobacter spp. received, 68% were Achromobacter xylosoxidans and 16% Achromobacter insuavis. Other species were present at lower proportions.

ST-739 and ST-741 were the most frequent types for Burkholderia multivorans. ST-137 and ST-175 were the most frequent types for Achromobacter xylosoxidans.

Conclusions: BCC number declined while GNNF number increased over the years.

Not all Belgian centres are referring isolates. More centres should include isolates for a better representation over the whole country.

Frequent ST such as Achromobacter xylosoxidans ST-137 should be further investigated. This type is also frequent among CF patients in France.

Presenter email address: denis.pierard@uzbrussel.be
An outbreak of scabies in the north-east region of Ghana

Yaw Amoako*, Richard Phillips², Joshua Arthu², Mark Abugri², Emmanuel Akowuah², Kwabena Oppong Amoako⁵, Benjamin Aboagye Marfo³, Sofanne Ravensbergen⁷, Ymkje Stienstra⁷

¹Komfo Anokye Teaching Hospital and Kumasi Centre for Collaborative Research, Kumasi, Ghana, ²Kwame Nkrumah University of Science and Technology, Kumasi Centre for Collaborative Research, Kumasi, Ghana, ³Komfo Anokye Teaching Hospital, Kumasi, Ghana, ⁴East Mamprusi Municipal Health Directorate, Kumasi, Ghana, ⁵Kwame Nkrumah University of Science and Technology, Kumasi Centre for Collaborative Research, Kumasi, Ghana, ⁶Ghana Health Service, Accra, Ghana, ⁷University Medical Center, Groningen, Netherlands

Background: Scabies is a parasitic disease of the skin with high global burden. In September 2019, there were reports of scabies among communities in the East Mamprusi Municipality of Ghana’s North East Region. The municipal health team treated individual patients with scabies within the communities. Due to continued reports of scabies, a medical team visited the district to further assess the scabies burden.

Materials/methods: Persons were invited to participate in an interview during house and school visits. All participants underwent a standardised history and skin examination using a REDCap based questionnaire. The diagnosis of scabies was based on criteria developed by the International Alliance for the Control of Scabies (IACS). Impetigo was diagnosed based on standard criteria.

Results: In all, 283 participants were interviewed. The majority were female (n=174, 61%) and the median age of the participants was 19 (IQR 13-25) years old. Itch was reported by 79% participants with a median duration of 30 days (IQR 21-60). Twenty-five (27%) of 93 high school students with scabies were treated with benzyl benzoate in the past two months compared to 57% of 190 community members. Nevertheless, the prevalence of scabies was 7.1% based on the IACS diagnostic criteria. Only 3% of the participants had no known scabies contact in the past weeks. Ninety four (47%) of the participants had moderate and 71 (35.5%) had severe scabies and 53 (18.7%) had impetigo.

Conclusions: The prevalence of scabies was extremely high in this population. IACS diagnostic criteria of scabies were helpful to assess the burden of the outbreak. Earlier treatment of individuals without treatment of contacts, did not reduce the scabies burden. Mass drug administration (MDA) is needed to substantially reduce the burden of scabies in this population. To control such outbreaks, and to develop a global control programme, studies on optimal implementation of MDA, especially in larger, non-isolated areas are desperately needed.

**Infection control, antimicrobial consumptions and incidence of hospital-acquired *Clostridioides difficile* infection in acute care hospitals in Catalonia**

Lucía Boix-Palop,*1,2,3, Laila Castella1, Ana Hornero5, Nieves Larrasa6, Pepita Perez7, Nieves Sopena4, Santiago Grau3,8, Sergi Hernández1, Ariadna Padülles1,5, Montserrat Gimenez3,4, Ricardo Ferrer3,6, Susana Melendo6, Juan P. Hocajada1,8, Esther Calbo Sebastian1,2,3

1Mútua Terrassa University Hospital, Terrassa, Spain, 2Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain, 3VINCAT Program Surveillance of healthcare related infections in Catalonia, Barcelona, Spain, 4Hospital Germans Trias i Pujol, Badalona, Spain, 5Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain, 6Vall d’Hebron University Hospital, Barcelona, Spain, 7CatLab (Parc Logístic de Salut), Viladecavalls, Spain, 8Hospital del Mar, Barcelona, Spain

**Background:** Hospital-acquired *Clostridioides difficile* infection (HA-CDI) is a major infection control (IC) challenge. We hypothesized that variations in HA-CDI rates between hospitals could be attributable either to differences in IC policies or to antimicrobial consumption (Antimicrob-C).

To assess the association of HA-MRSA rates (a surrogate marker of IC policies) and Antimicrob-C with HA-CDI incidence from 2011 to 2018 in hospitals reporting at the VINCat-program (IC and Antimicrobial Stewardship Catalan Program)

**Materials/methods:** Data on 45 hospitals (with 70.5% of all adult acute-hospital beds) reporting Antimicrob-C, HA-MRSA and HA-CDI new cases to the VINCat-program have been analysed. To report the Antimicrob-C the ATC/DDD index 2018 was used. Participating hospitals were classified into three groups: Group-I (>500 beds): 9 hospitals, Group-II (500-200 beds): 15 hospitals, Group-III (<200 beds): 21 hospitals. The number of hospitalization-days recorded at the participating hospitals increased from 2,828,101 in 2011 to 3,201,680 in 2018.

To analyze the association between study outcome HA-CDI rate and the Antimicrob-C rate as main exposure, a Poisson regression model was used. HA-MRSA rate, year and hospital group were included in the model as confounding factors that could bias the relationship between the outcome and the main exposure. The exponents of model coefficients are equal to incidence rate ratios (IRR).

**Results:** The table shows the HA-MRSA and HA-CDI rates and DDD/100 bed-days per year.

</tr>
</tbody>
</table>

The regression model showed a positive association between Antimicrob-C and HA-CDI rates (IRR = 1.01, CI 95% 1.01 – 1.02 p<0.001). The percent change in HA-CDI incident rate is by 1% for every 10 DDD increase in Antimicrob-C rate, independently of HA-MRSA rate, year and hospital group. Likewise, the incident rate for HA-MRSA was significantly associated to HA-CDI (IRR = 1.68, CI 95% 1.36-2.07 p<0.001).

**Conclusions:** This study shows a clinically relevant association between HA-CDI and Antimicrob-C rates. Results suggest that antimicrobial stewardship programs are needed to improve the control of HA-CDI in Catalonia.

Reduced clinical improvement after treatment for urethritis in men with azithromycin resistant Mycoplasma genitalium

Joyce Fallon Braam*, Alje Van Dam1,2, Sylvia Bruisten1,2, Maarten F. Schim Van Der Loeff1, Martijn Van Rooijen2, Henry De Vries1,2, Clarissa Vergunst1,3

1 Public Health Service of Amsterdam, Department of Infectious Diseases Research and Prevention, Amsterdam, Netherlands, 2Academic Medical Center, Amsterdam, Netherlands, 3NWZ, Department of Dermatology, Den Helder, Netherlands

Abstract third-party references: Department of Infectious Diseases Research and Prevention, Public Health Service of Amsterdam, Amsterdam, the Netherlands;

Background: Mycoplasma genitalium (MG) is associated with urethritis in men. Clinical improvement in men treated syndromically for urethritis was examined and correlated to MG positivity and macrolide resistance.

Materials/methods: Urethritis was defined as the presence of >10 leucocytes per high power field in Gram stains of urethral discharge in men with urethritis symptoms. Additional presence of intracellular gram-negative diplococci defined gonococcal urethritis. Point-of-care therapy for gonococcal urethritis was 1000mg ceftriaxone IM and for non-gonococcal urethritis 1000mg azithromycin PO. From 15th May 2018 until 4th September 2019 urine samples of all men with urethritis were tested for Neisseria gonorrhoeae (NG), Chlamydia trachomatis (CT), and MG using TMA assays (Aptima, Hologic). Macrolide resistance-associated mutations in MG were detected by PCR. Patients received a question about clinical improvement in a text message two weeks after therapy.

Results: The study included 2033 men with 2181 episodes of urethritis. Of all episodes, 584/2181 (27%) patients had NG, 666/2181 (31%) CT, and 497/2181 (23%) MG. Macrolide sensitivity of MG infections could be determined in 350 (70%) samples of which 259 (74%) were macrolide resistant. Of the 640 (31%) text message responders 509 (80%) indicated that their symptoms were reduced or gone (table 1). The improvement percentage was lower for patients infected with MG compared to those without MG infection. Patients with macrolide resistant MG (46/79, 58%) reported less often improvement compared to patients with macrolide sensitive MG (20/24, 83%) (p=0.025) especially in patients with resistant MG without CT or NG co-infection (26/53, 49%).

Conclusions: Patients with urethritis and macrolide resistant MG had a worse clinical outcome after standard treatment compared to patients with macrolide sensitive MG or without MG infection. The clinical utility of testing for MG and macrolide resistance among men with urethritis should be evaluated.

Table 1: Treatment success among 640 patients with urethritis responding to text message.

Prevalence of macrolide resistance mutations in *Mycoplasma pneumoniae* from patients with respiratory tract infections in European Russia

Inna Edelstein*1, Andrey Romanov1, Alexey Y. Kuzmenkov1, Natalia Alyabyeva2, Tatiana Pleskachevskaia1, Marina Erschova4, Irina Ivanova1, Antonina Ignatkova6, Oleg Romashov7, Elena Groshenkova8, Roman Kozlov1

1Smolensk State Medical University, Institute of Antimicrobial Chemotherapy, Smolensk, Russian Federation, 2National Medical Research Center for Children’s Health, Moscow, Russian Federation, 3Smolensk State Medical University, Smolensk, Russian Federation, 4Infectious diseases hospital, Yaroslavl, Russian Federation, 5Mari El Republican center for prevention and control of AIDS and infectious diseases, Yoshkar-Ola, Russian Federation, 6Center of hygiene and epidemiology of Tula region, Tula, Russian Federation, 7Smolensk military hospital, Smolensk, Russian Federation, 8Centers for disease control in Yaroslavl region, Yaroslavl, Russian Federation

Background: *Mycoplasma pneumoniae* (*MPN*) is the most common ‘atypical’ bacterium causing lower respiratory tract infections (LRTI). Macrolides (ML) are the drugs of choice for treating *MPN* infections, however, in recent years; there have been numerous reports of emerging ML -resistance in *MPN*. *MPN* is a fastidious, difficult to culture organism, which is why routine phenotypic detection of resistance is extremely challenging and impractical. We aimed to assess the prevalence of M-resistance in *MPN* in Russia, using real-time PCR detection of macrolide resistance-associated mutations directly from clinical specimens.

Materials/methods: We collected 1 324 non-duplicate *MPN*-positive throat swabs for by routine diagnostic PCR from patients with LRTI, mostly pneumonia (n=1052), in seven cities in the European part of Russia from 2013 to 2019 (606 samples were collected during the peak incidence of community pneumonia in 2018). ML-resistance mutations in the 23S rRNA gene were detected using real-time PCR assay and confirmed by the independent PCR and sequencing. The data on identification of ML-resistance genotypes of *MPN* were deposited to the AMRmap web site (http://AMRmap.net), an online platform for the analysis of AMR surveillance data in Russia.

Results: A total of 258 (19.5%) of the 1324 samples revealed the presence of ML-resistance mutations in the 23S rRNA gene of *MPN*. The detected genotypes were (in order of decreasing prevalence): A2058G [216/1324, 16.3%] and A2059G [33/1324, 2.5%], A2062C [2/1324, 0.2%], A2062G [1/1324, <0.1%]. Five rare double- and triple-mutation genotypes were detected for the first time: A2058G+2059G [4/1324, 0.3%], A2059G+2062C [2/1324, 0.2%], A2058G+2059G+2062C [1/1324, <0.1%], and A2058G+A2059G+A2062C [1/1324, <0.1%].

Conclusions: This study revealed high prevalence (19.5%) of macrolide resistance mutations in *MPN* in the European part of Russia, but decreased prevalence (15.3%) during the outbreak period in 2018.

**Impact of proposed revised EUCAST breakpoints on susceptibility classification of contemporary Danish mould isolates**

Karin Meinike Jørgensen*1, Raluca Datcu1, Rasmus Krøger Hare2, Maiken C. Arendrup1,2,3

1Unit of Mycology, Statens Serum Institut, Copenhagen, Denmark, 2Dept. of Clinical microbiology, Rigshospitalet, Copenhagen, Denmark, 3Dept. of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

**Background:** EUCAST breakpoints v 9.0 are undergoing revision following the revised definition of the "I" category from "Intermediate" to "Susceptible, Increased exposure". An area of technical uncertainty (ATU) has been proposed for several compounds and species. For isavuconazole and posaconazole, the recommendations are to interpret an MIC in the ATU as S or R dependent on the susceptibilities to voriconazole and itraconazole, respectively. For voriconazole and itraconazole, the recommendation is to report as R with the following comment: "In some clinical situations (non-invasive infections) voriconazole/itraconazole can be used provided a sufficient exposure is ensured". Here, we compare susceptibility classifications according to the current and proposed EUCAST breakpoints.

**Materials/methods:** 639 Aspergillus isolates obtained during 2018. E.Def 10.1 screening for azole-R. A. fumigatus. E.Def 9.3.1 susceptibility testing of non-S and a selection of S A. fumigatus (N=217-253 for voriconazole, itraconazole and posaconazole) and other Aspergillus species isolates. Isolates from the same patient with identical species and susceptibility patterns were excluded if sampled less than 21 days apart. EUCAST breakpoints v 9.0 and proposed v 10.0 were compared for susceptibility classification. Fisher’s test was used for statistical analysis.

**Results:** With the proposed breakpoints, statistically significant changes in resistance were seen for A. fumigatus for isavuconazole and voriconazole. For the remaining species, no or slight increases in the numbers of resistant isolates were found. Of note, the numeric increase in itraconazole R A. terreus was due to several resistant isolates from one patient and not nationwide increased resistance. For isavuconazole and posaconazole, the breakpoint revision affected the S-category for A. fumigatus, as more (92.8% vs. 77.4%) were isavuconazole S and 11/15 isolates currently classified as posaconazole I were classified as S (93.2% vs. previously 91.3%).

**Conclusions:** Adoption of the proposed EUCAST breakpoints v 10.0 on contemporary Danish Aspergillus isolates resulted in a uniform susceptibility classification across the azoles in line with clinical experience. The ATU has been introduced to avoid misclassifications where S and R populations overlap. This has reduced the number of misclassifications of isavuconazole and posaconazole wild-type isolates as non-susceptible.

**Table.** Comparison of MICs (mg/L) and percent resistant isolates using the v 9.0 and proposed v 10.0 EUCAST breakpoints (BPs). Proposed S/R/ATU are included (mg/L) and those deviating from current ones are underlined. P-values are included in parenthesis where statistically significant (P<0.05) change in susceptibility is seen. (NA: not available, No BP: no breakpoints established for that drug and species)

Background: The genus Enterobacter is among the main etiologies of nosocomial infections, composed by species that share diverse phenotypic and genotypic features, as a constitutive β-lactamase AmpC. Historically, the most frequent Enterobacter species at the clinical setting were those belonging to the E. cloacae complex and E. aerogenes. In 2018, E. aerogenes has been classified as Klebsiella aerogenes, due to its greater genotypic similarity with the genus Klebsiella. Our objective was to characterize and compare the clinical profile [risk factors, presentation, prognosis] of the bacteraemias caused by E. cloacae and K. aerogenes.

Materials/methods: Prospective cohort study. Multicentre [five university Spanish hospitals]. Period: 3 years. All the patients with bacteraemia caused by E. cloacae or K. aerogenes were included. Species were identified with MALDI-TOF. We analysed baseline characteristics [chronic comorbidities, previous therapies, invasive devices], features of the bacteraemia [source, severity, treatment], microbiological characteristics [susceptibility to antibiotics, resistance mechanisms] and prognosis [30-days mortality]. Statistical analyses were performed with SPSS.

Results: The study included 285 patients, 196 (68.7%) with E. cloacae and 89 (31.3%) with K. aerogenes. Both groups showed no differences in age, sex, most comorbidities, previous invasive devices, place of acquisition, sources or severity, but they differed in the Charlson score and previous antibiotic therapy [table]. Venous catheter was the most frequent source [31.1% for E. cloacae and 29.2% for K. aerogenes, p=0.608]. Mortality was 19.4% for E. cloacae and 20.2% for K. aerogenes, p=0.869. Susceptibility to antibiotics was similar for both species, except for cefepime and imipenem.

**Abstract third-party references:** Fundació Docència i Recerca Mútua Terrassa

**Background:** Pneumocystis jirovecii pneumonia (PJP) is an increasing, life-threatening infection in non-HIV immunosuppressed patients. Clinical implications of coinfection with other respiratory pathogens are poorly described.

Our aim was to describe clinical characteristics and prognosis of patients with PJP and other respiratory coinfections.

**Materials/methods:** Multicentre, observational, retrospective study. Setting: five acute-care teaching hospitals. Period: January-2011 to August-2017. Cases: adult patients diagnosed with PJP and other bacterial, fungal or viral coinfection in a respiratory specimen in a susceptible host with compatible clinical syndrome and radiologic characteristics.

**Results:** One hundred and fifteen patients were included; 63 (55%) presented respiratory coinfection. Thirty-two patients (28%) presented viral coinfection, mostly cytomegalovirus (18; 56%). Nineteen patients (16%) had bacterial coinfection. Six patients (5%), fungal coinfection; all of them were Aspergillus spp. Patients with Aspergillus coinfection had a solid malignancy in 70%, received high-dosing corticosteroids in 83% and presented with serious respiratory failure (median PFR of 194, IQR 160-220).

Differences between co-infected and no-coinfected patients are shown in Table 1:

</table>

\(^1\)Median, interquartile interval [IQR]. \(^2\)\(\geq 16-20 \text{ mg/day of prednisolone (or equivalent dose), } \geq 4 \text{ weeks.} \(^*\)At diagnosis.

**Conclusions:** More than a half of patients with PJP presented respiratory coinfection, mostly viral. Co-infected patients had longer diseases and a bronchoalveolar radiological pattern. Mechanical ventilation was more frequent and hospital stay longer in co-infected patients but in-hospital mortality was similar in both groups.

**Presenter email address:** beatriz.dietl@gmail.com
Bloodstream infections caused by *Staphylococcus aureus* non-susceptible to daptomycin: clonal and clinical aspects

Debora S. Fernandes¹, Rennan Wladyka², Adriana Lucia Pires Ferreira², Simone Nouer*², Kátia Dos Santos¹

¹IMPPG Instituto de Microbiologia Prof Paulo Goes, UFRJ, Rio de Janeiro, Brazil, ²Hospital Universitário Clementino Fraga Filho, UFRJ, Rio de Janeiro, Brazil

Background: *Staphylococcus aureus* is one of the leading pathogens isolated from bloodstream infections (BSI). Vancomycin or daptomycin have been the main choice of therapy for MRSA (methicillin-resistant *S. aureus*) BSI. VISA (vancomycin-intermediate *S. aureus*), hVISA (heteroresistant-VISA), and non-susceptibility to daptomycin strains have already been described. This study aimed to evaluate clinical aspects associated with the resistance and clonality of *S. aureus* isolated from BSI, between 2016 and 2018.

Materials/methods: minimum inhibitory concentrations (MICs) were evaluated for five antimicrobials by the broth microdilution method. MICs for ceftaroline and vancomycin of the MRSA isolates were determined by the E test®. Screening with BHI agar added with vancomycin and the population profile/area under the curve (PAP/AUC) test were used to diagnose VISA/hVISA. SCCmec type was evaluated by PCR and the clonal profile by PFGE method. The patient’s clinical data were analyzed in association with the microbiological one.

Results: Among 123 *S. aureus* isolates from BSI, 31% were MRSA. MIC₅₀ and MIC₉₀ values were: 2 / 2 µg/mL to daptomycin; 1 / 1 µg/mL to linezolid; 1 / 256 µg/mL to oxacillin; 0.5 / 0.5 µg/mL to teicoplanin and 1 / 1 µg/mL to vancomycin. MIC values for ceftaroline and vancomycin by the E test® were 0.75 and 2 µg/mL. 75% of the isolates were not susceptible to daptomycin. Clonal lineages and SCCmec types found were USA100/ST5-II (50%), USA800/ST5-IV (22%), USA300/ST8-IV (16%), USA1100/ST30-IV (5%), BEC/ST239-III (5%) and one isolate carrying SCCmecV/ST1. One VISA and three hVISA isolates were found, associated with the USA100 and USA300 lineages. MRSA isolates were prevalent in patients had vascular catheter (85%). Age (67.5 versus 58 years; p=0.03) and mortality was associated with MRSA infections (55.6% versus 36.6%; p=0.04). End-stage renal disease was associated with MSSA infections (50.7% versus 27.3%; p=0.03).

Conclusions: Daptomycin non-susceptibility, VISA and hVISA phenotypes were associated with prevalent clonal lineages. These strains had no impact on mortality.

Incidence rates of multidrug-resistant indicator pathogens increase in hospitalised horses during stay
Anne Kauter, Antina Lübke-Becker, Dania Kannapin, Sabita D. Stöckle, Lennard Epping, Robin Köck, Torsten Semmler, Heidrun Gehlen, Birgit Walther

1Robert Koch Institute, Advanced Light and Electron Microscopy, Berlin, Germany, 2Freie Universität Berlin, Institute of Microbiology and Epizootics, Berlin, Germany, 3Freie Universität Berlin, Equine Clinic: Surgery and Radiology, Berlin, Germany, 4Robert Koch Institute, Microbial Genomics (NG1), Berlin, Germany, 5DRK Kliniken Berlin, Berlin, Germany

Abstract third-party references: Federal Ministry of Education and Research (BMBF) (project numbers 01K11727D and 01K11727F)

Background: In previous studies, veterinary clinics were recognized as hot-spots for spread of multidrug-resistant (MDR) opportunistic and zoonotic pathogens such as Staphylococcus aureus (MRSA) and extended-spectrum beta-lactamase producing Escherichia coli (ESBL-E). Strategies to decrease the MDR incidence rates among hospitalized horses include hygiene management improvements and evidence-based antibiotic stewardship (ABS). Here we present preliminary data on MDR incidence rates obtained from horses suffering from colic receiving divergent perioperative antibiotic regimes.

Materials/methods: Horses subjected to laparotomy were assigned to two distinct groups defined by the length of their antibiotic courses. The first group was treated with the conventional protocol [CP], i.e. perioperative administration of a penicillin/gentamicin combination for five days. The second group of horses received the same combination, but this protocol includes a single shot [SP] prior to colic surgery only. Fecal samples and nostril swabs were collected directly at hospital admission (t0) as well as on days three (t1) and 10 (t2) after surgery. All samples were screened for ESBL-E and MRSA using microbiological diagnostics.

Results: So far, incidence rates were available for 77 horses receiving abdominal surgery. Due to different medical conditions, mainly defecation problems and sudden death or euthanasia due to animal welfare, some fecal samples were not available. Overall, 10% of the valid fecal samples from t0 (n=50) were positive for ESBL-E. coli and 7% of the valid nostril swabs (n=76) were positive for MRSA. In the CP group, the ESBL-E incidence rate raised to 67% at t1 and t2, while the MRSA carriage rates increased to 49% (t1) and 50% (t2). With a rate of 40% for ESBL-E and 24% for MRSA, the SP group showed lower incidences at t1 compared to the CP group. However, on day ten of the hospital stay (t2), the incidences reached those of the CP group for enteral carriage of ESBL-E (65%), while the MRSA rate (30%) was still lower.

Conclusions: MDR indicator pathogen incidence rates increase in horses with laparotomy over time. Further efforts with respect to ABS and targeted hygiene regimes are needed to counteract MDR accumulation among hospitalized horses.

Abstract 4275

Suitability of ceftazidime for continuous infusion in outpatient parenteral antimicrobial therapy

Felicity Drummond¹, Conor Jamieson*, Laima Ozolina², Alan-Shaun Wilkinson²

¹British Society for Antimicrobial Chemotherapy, Birmingham, United Kingdom, ²BioPharma Stability Testing Laboratory, Nottingham, United Kingdom

Abstract third-party references: On behalf of Members of the BSAC Working Group on Drug Stability Testing

Background: Ceftazidime is a beta-lactam cephalosporin used to treat Gram-negative bacterial infections, including Pseudomonas aeruginosa. Ceftazidime is unstable in aqueous solution leading to the formation of pyridine, a toxic degradation product. Safe use of ceftazidime in an outpatient parenteral antimicrobial therapy (OPAT) setting relies on controlling its temperature and concentration. Administration of ceftazidime in elastomeric devices would provide a convenient option for OPAT services. This study sought to establish extending the shelf-life for ceftazidime in aqueous solution in two different elastomeric devices at two different concentrations commonly used in clinical practice. The study design was to meet the acceptance criteria of the UK National Health Service (NHS) Yellow Cover Document (YCD) requirements and for pyridine the British Pharmacopoeia (BP) limit to ensure patient safety.

Materials/methods: Stability of ceftazidime was assessed according to latest UK NHS YCD and BP requirements in two different 1 day elastomeric devices and concentrations (0.9% w/v saline at 12 mg/mL and 25 mg/mL). Devices were stored at 2-8°C for 48 hours, room temperature for 3 hours and 32°C for 12 hours. Concentrations of ceftazidime and pyridine were assayed using a validated LC method.

Results: The BP limit for loss of ceftazidime solutions for injection is 90-110%; while pyridine levels are limited to not more than (0.5% (w/w). Recorded losses of ceftazidime and pyridine levels were within these limits following storage at 2-8°C for 48 hours and 12 hours infusion.

Conclusions: Ceftazidime can be formulated and stored for 48 hours at 2-8°C followed by a 12-hour infusion period at 32°C while maintaining acceptable concentrations of active ingredient; at the same time pyridine levels did not exceed the BP limit. Our data show there is a role for ceftazidime infusion over 12 hours for OPAT services which have the capacity to prepare devices and use them within 48 hours. This model will not suit all OPAT services but provides a useful treatment option for services which can deliver it and can help to reduce the reliance on broad spectrum agents such as piperacillin/tazobactam and meropenem.

Abstract 4276

**Increased carriage of ESBL-producing Enterobacteriaceae among men who have sex with men**

Eline Van Dulm*1, Ward Van Bilsen1, Amy Matser1, Ineke Linde1, Yvonne Van Duijnhoven1, Jan Prins2, Maria Prins1,2, Anders Boyd1,3, Alje Van Dam1

1Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands; 2Amsterdam UMC, University of Amsterdam, Department of Internal Medicine, Amsterdam, Netherlands; 3HIV Monitoring Foundation, Amsterdam, Netherlands

**Background:** Carriage of rectal extended spectrum β-lactamase Enterobacteriaceae (ESBL-E) occurs in 5.0% of the Dutch population. Several studies suggest that men who have sex with men (MSM) might be at increased risk for carriage of resistant bacteria. We aimed to determine the prevalence and determinants of rectal ESBL-E carriage among MSM in Amsterdam, the Netherlands.

**Materials/methods:** We screened MSM participating in the Amsterdam Cohort Study for rectal ESBL-E carriage between April and December 2018. Self-administered questionnaires were used to measure sexual behavior and possible risk factors for antibiotic resistance. Determinants of ESBL-E carriage were identified using logistic regression analysis.

**Results:** We included 583 MSM, of whom 141 (24%) reported use of antibiotics within the last 6 months. In total, 16.3% (95%-confidence interval (CI) 13.3-19.2%) of MSM tested ESBL-E positive. ESBL-E carriage was associated with younger age (being 18-34 years old) and higher education status. Compared to having ≤1 sexual partner in the past 6 months, the odds of being ESBL-E positive were no different for MSM with 2-5 sexual partners (adjusted odds ratio (aOR) 0.86, CI 0.35-2.08), but significantly higher for MSM with ≥5 sexual partners in the same timeframe (aOR 4.32, CI 2.02-9.25; p<0.001) after adjusting for age, and antibiotic use and travel history of the preceding 6 months. Condomless receptive fellatio with casual partners was associated with ESBL-E carriage (aOR 2.23, CI 1.26-3.97; p=0.006). HIV-status, antibiotic use and travel history were not associated with ESBL-E carriage.

**Conclusions:** ESBL-E prevalence in MSM is much higher than in the overall Dutch population, which might be explained by sexual transmission. Our data imply that MSM should be considered a risk group for ESBL-E carriage, and might warrant different isolation precautions and empirical antibiotic treatment if admitted to hospitals.

Abstract 4277

Diagnostic accuracy of VIDISCA-NGS in patients with suspected central nervous system infections

Ingeborg Van Zeggeren*1, Arthur Wouter Dante Edridge1, Diederik Van De Beek1, Martin Deijs1, Sylvie Koekkoek1, Katja Wolthers1, Lia Van Der Hoek1, Matthijs Brouwer1

1Amsterdam University Centers, location AMC, Amsterdam, Netherlands

Background: Confirming the diagnosis in viral central nervous system (CNS) infections can be difficult with current available diagnostic tools. Virus discovery cDNA-AFLP next generation sequencing (VIDISCA-NGS) is a promising viral metagenomic technique, which enables detection of all viruses in a single assay. Yet, its diagnostic accuracy to detect viruses in cerebrospinal fluid (CSF) of patients with suspected CNS infections is unknown. With this study we aimed to determine the diagnostic accuracy of VIDISCA-NGS in CSF of patients with suspected CNS infections.

Materials/methods: Between 2012-2015, all adult inpatients or patients presenting to the Emergency Department, in whom a lumbar puncture was performed for the suspicion of a CNS infection, were prospectively included in a cohort study. Patients from this cohort were included in this study if 1) they were diagnosed with a viral CNS infection, or 2) a viral CNS infection was initially suspected but eventually a different diagnosis was made. A qPCR panel of the most common causative viruses was performed on CSF of these patients as a reference standard and compared to the results of VIDISCA-NGS, the index test.

Results: We included 38 patients with viral CNS infections and 35 presenting with suspected CNS infection for whom an alternative etiology was finally established. We found an overall sensitivity and specificity of 52% (95% CI 31-73%) and 100% (95% CI 91-100%), respectively. One enterovirus that was detected by VIDISCA-NGS was only identified by qPCR upon retesting. Additional viruses identified by VIDISCA-NGS consisted of GB virus C, human papilloma virus, human mastadenovirus C, Merkel cell polyoma virus and anelloviruses.

Conclusions: In patients for whom routine diagnostic work-up does not yield a causative pathogen, VIDISCA-NGS can be of additional value as it can detect a broader range of viruses, but it does not perform well enough to replace routine PCR.

Respiratory syncytial virus bronchiolitis and recurrent wheezing: a 1-year follow-up study

Padmasani Venkat Ramanan, Kaveri Subbiah

1Sri Ramachandra Institute Of Higher Education And Research, Chennai 116, India, 2Sri Ramachandra Institute of Higher Education and Research, Chennai, India

Background: Recurrence of wheeze is common after bronchiolitis. This could be due to the infection interfering with lung development and immune maturation or the infection may be the earliest stimulus for wheezing in children with underlying genetic susceptibility. There is a wide variation in the reported incidence of recurrence of wheeze following bronchiolitis. Recent studies have suggested that rhinovirus-associated bronchiolitis is a greater risk factor for development of recurrent than respiratory syncytial virus (RSV). This study was done to assess the incidence of recurrence of wheeze, over a one year follow-up period after hospitalization for RSV or non-RSV bronchiolitis.

Materials/methods: This prospective single centre cohort study was done in children hospitalized with bronchiolitis between September 2016 and August 2018 in a university teaching hospital in South India. Those with chronic underlying diseases, congenital malformations and inability to complete a one year follow up were excluded. The clinicodemographic details were noted during the hospital stay for the first episode. Monthly structured phone interviews were done for 12 months to enquire about the number of recurrences. The primary outcome was recurrence of wheeze at the end of one year.

Results: During the study period a total of 174 children with bronchiolitis were enrolled out of which 150 completed the study. 82 (47%) were positive for RSV infection. Within the first year after hospitalization, 67% children with non-RSV bronchiolitis developed recurrent wheezing, compared with 56% of RSV bronchiolitis. The difference was statistically significant (p=0.01). The Odd’s ratio of recurrence of wheeze in children with non RSV bronchiolitis was 1.45 [95% confidence interval (CI) 1.02-1.87]. 32.8% children with Non RSV bronchiolitis and 26% children with RSV bronchiolitis developed more than one episode of recurrence thus meeting the GINA definition of asthma (>3 episodes of wheeze in a lifetime).

Conclusions: Children hospitalized with bronchiolitis caused by viruses other than RSV have higher risk recurrence of wheezing during a 1-year follow-up period than children with RSV bronchiolitis [OR 1.45 [95% CI 1.02-1.87]].

Abstract 4279

Epidemiology and clinical characteristics of upper urinary tract infections in infectious diseases emergency department of a tertiary teaching hospital in Slovenia

Kristina Nadrah*1, Mateja Logar*

1Department of Infectious Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: Urinary tract infections (UTI) are common infections. With the aging population, we sought to explore the epidemiology of upper UTI in patients referred to our infectious diseases emergency room.

Materials/methods: We performed a retrospective review of the records of patients ≥18 years who visited emergency room of our department from March 2018 to August 2019 and were diagnosed with an upper UTI. Only patients with symptoms of upper UTI (frequency, urgency, dysuria, flank pain, pyuria or fever) were included. Healthcare-associated (HA) infections were considered in patients who were hospitalized ≥2 days in the previous 30 days or in nursing home residents, others were considered community-acquired (CA). Data were statistically evaluated using t-or chi-square test.

Results: 123 episodes were identified, of which the majority were CA (86%) and complicated (72%). Patients were admitted in 45 episodes (36.5%), median for 6 days (1 – 22 days). Antibiotics were prescribed prior referral in 47 cases (38%), most frequently a fluoroquinolone (42.5%). Urine culture most commonly yielded Escherichia coli (43%), which was pansusceptible in 47%, resistant to fluoroquinolones in 19%, and ESBL producing in 6.5%. In those with negative urine culture, 77% received prior antibiotics. Hospitalized patients had more comorbidities (median Charlson index 4 vs. 1, p = 0.01), were more often male (44% vs. 27% p = 0.04) and more often had anatomical or functional abnormalities (69% vs. 40%, p = 0.001). Cefuroxime axetil (46%) or a fluoroquinolone (31%) were most frequently prescribed to outpatients, and in hospitalized patients ertapenem (24%) or parenteral cefuroxime (20%). De-escalation was more frequent in hospitalized patients (11 vs. 3, p = 0.0005). Intravenous-oral switch was performed in 56% of hospitalized patients. There were no differences in clinical failure between hospitalized patients and outpatients (11% vs. 9%, p = 0.7).

Conclusions: Patients referred to our clinic were often prescribed antibiotics prior to the visit which thus interfered with pathogen detection. Broad-spectrum antibiotic therapy was prescribed more often in hospitalized patients, but was de-escalated more often as well. Clinical outcome was favourable in both groups.

Characterisation and comparison of farm animal and human *Clostridioides difficile* isolates in Italy

Patrizia Spigaglia*, Fabrizio Barbanti†, Mariella Vescovi‡, Rossella Ceruti§, Clara Gaspano∥, Silvia Faccini‡, Marianna Merenda‡, Carlo Rosignoli‡

1Istituto Superiore di Sanità, Dep. Infectious Diseases, Rome, Italy, 2Istituto Zooprofilattico Sperimentale della Lombardia e dell’Emilia Romagna “B. Ubertini”, Mantova, Italy, 3Azienda Ospedaliera “Carlo Poma”, Mantova, Italy

Background: *Clostridioides* (*Clostridium*) *difficile* is one of the prevalent causes of healthcare-associated infections worldwide. Recently, a higher incidence and severity of *C. difficile* infection in both hospitals and community has been reported. This epidemiological change has been associated with the emergence of types, such as PCR-ribotype (RT) 027 and RT078, geographically widespread and able to infect various species. In particular, farm animals are recognized as possible reservoirs of *C. difficile*. Since information in Italy are still scant, this study, funded by the Italian Ministry of Health (RC IZSLER 07/15), aimed to characterize and compare human and animal isolates from Northern Italy.

Materials/methods: *C. difficile* isolates were typed using the capillary PCR-ribotyping method. Genes encoding for toxin A, B and binary toxin (CDT) were detected by PCR assays. Susceptibility analysis for moxifloxacin (MXF), erythromycin (ERY), tetracycline (TET), amoxicillin (AMX), metronidazole (MTZ) and vancomycin (VAN) was performed by Etest.

Results: 364 strains, 267 from animals (250 swine and 17 cattle) and 97 from humans were analyzed. The most frequent toxigenic profile of human isolates was A+B+CDT- (79 strains), while A+B+CDT+ (252 strains) was prevalent in animals. A higher number of different RTs was detected in humans compared to animals (28 and 11, respectively). The predominant type identified in humans was RT018 (39%), followed by RT014 and RT078 (both 8%). Conversely, RT078-lineage (RT033, RT045, RT066/2, RT078, RT126 and RT620) was predominant in animals (92%). Seven RTs (001, 005, 078, 085, 126, 620, 569) were common to both humans and animals. Susceptibility analysis showed that 98% of animal strains resistant to both ERY and MXF belonged to RT078-lineage, while isolates RT018 of human origin are known to be resistant to multiple classes of antibiotics.

Conclusions: These results indicated an overlap of several *C. difficile* RTs between human and animal Italian isolates. RT078-lineage was confirmed as one of the most successful lineage in animals, especially swine. Our data support farm animals a potential source of highly virulent and resistant *C. difficile* strains highlighting the necessity of a close *C. difficile* surveillance in Italy, in accordance with a One Health approach.

Real-life experience with bezlotoxumab for the prevention of recurrent Clostridioides difficile infection

Javier Cobo Reinoso1,2, Rosa Escudero Sánchez*,1,2, María Ruiz-Ruigómez3, Jorge Fernandez Fradejas1, Ángela Cano Yuste4, Angela Valencia Alijo5, Beatriz Díaz-Pollán6, Marina Muñoz Burgos2, Esperanza Merino De Lucas3, Oriol Martín Segarra9, Carmen Sáez10, Carlos Armiananzas Castillo12, Dolors Rodríguez-Pardo12, Julián De La Torre Cisneros2,6, Francisco Lopez-Medrano3

1 University Hospital Ramón y Cajal, Madrid, Spain, 2REIPI – Spanish Network for Research in Infectious Diseases, Madrid, Spain, 3 University Hospital 12 Octubre, Madrid, Spain, 4University Hospital Reina Sofia, Córdoba, Spain, 5University Hospital Puerta de Hierro, Madrid, Spain, 6University Hospital La Paz, Madrid, Spain, 7University Hospital Virgen del Rocío, Seville, Spain, 8General University Hospital Alicante, Alicante, Spain, 9University Hospital Alcorcon, Alcorcón, Spain, 10University Hospital La Princesa, Madrid, Spain, 11University Hospital Marqués De Valdecilla, Santander, Spain, 12University Hospital Vall d’Hebron, Barcelona, Spain

Background: Bezlotoxumab, a monoclonal antibody that blocks toxin B of Clostridioides difficile, reduce by 40% the rate of recurrent C.difficile infection (CDI) at 12 weeks (MODIFY studies). Clinical experience with bezlotoxumab out of clinical trials is very scarce. The aims of our study were to describe the characteristics of patients who received bezlotoxumab after commercialization and analyze its efficacy and safety in a real-life context of Spanish hospitals.

Materials/methods: Retrospective, multicenter observational study. All consecutive patients who receive bezlotoxumab between July/2018 to June/2019 in eleven Spanish participant hospitals were included. Recurrence was defined as the appearance of a new episode of CDI within 12 weeks after bezlotoxumab infusion. Risk factors for CDI recurrence used in MODIFY studies (age over 65, immunosuppression, previous episode, hypervirulent ribotypes and severe CDI according to Zar’s criteria) were recorded in order to compare our cohort with patients treated with bezlotoxumab in MODIFY trials.

Results: Seventy-eight patients were included. Median age was 70.5 (59-82). The next table shows percentage of patients having risk factors for CDI recurrence both in our cohort and in bezlotoxumab treated patients in MODIFY studies.

<table>
<thead>
<tr>
<th>Risk Factor</th>
<th>Present cohort</th>
<th>Bezlotoxumab treated (MODIFY)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age≥65</td>
<td>65.4%</td>
<td>49.9%</td>
</tr>
<tr>
<td>Immunocompromised</td>
<td>62.8%</td>
<td>22.8%</td>
</tr>
<tr>
<td>Previous CDI</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Hypervirulent strains</td>
<td></td>
<td>27.7%</td>
</tr>
<tr>
<td>Severe episode</td>
<td></td>
<td>18.2%</td>
</tr>
</tbody>
</table>

No patients in our cohort lacked risk factors for CDI recurrence and 87.2% had 2 or more risk factors. Correspondent figures in MODIFY trials were 24% and 49.6%. Most of the patients received vancomycin (57 cases; 73.1%) as anti C.difficile treatment. Recurrence rate at 12th weeks was 14.1%, (16.5% in MODIFY trials). Median time to recurrence was 39 days (IQR:14-45). There were no adverse effects related to bezlotoxumab in opinion of the investigators, and only one patient died due to CDI. Neither age, type of risk factor for recurrent CDI nor anti CDI treatment were associated with failure of bezlotoxumab.

Conclusions: In spite of being used in patients with higher risk CDI recurrence than those included in MODIFY trial, bezlotoxumab was associated with a similar rate of recurrence in a real-life context. We were unable to find factors associated with failure of bezlotoxumab.

Impact of antimicrobial stewardship and infection control programmes on the incidence of carbapenem-resistant Pseudomonas aeruginosa: a non-linear time-series analysis

Marianna Meschiari, César Nebot, Arielle Bejaert, Mario Sarti, Claudia Venturelli, Gabriella Orlando, Jose Maria Lopez Lozano, Cristina Mussini

1Infectious Disease Clinic, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy, 2Research Group on Health Sciences Data Analysis. University of Murcia, Murcia, Spain, 3Economics. Centro Universitario de la Defensa UPCT, San Javier, Spain, 4Research Group in Time Series and Econometrics. University of Murcia, Murcia, Spain, 5Clinical Microbiology Laboratory, University Hospital of Modena, Modena, Italy

Abstract third-party references: supported by THRESHOLDS study group

Background: Carbapenem resistance in Pseudomonas aeruginosa (PaCRE) is an important cause of nosocomial infections associated with high level of resistance, morbidity and mortality rate. Estimate the impact of antimicrobials stewardship (ABS) and infection control programmes on the emergence of (PaCRE).

Materials/methods: A time-series analysis exploring temporal associations between sequential infection control interventions (hand hygiene [iHAND Campaign], carbapenem sparing strategy [iCARBA Campaign], ABS with periodical audit and feedback [iASP Campaign]) and Incidence Density of Carbapenem-resistant Pseudomonas aeruginosa (Di_PaCRE) in Azienda Ospedaliero-Universitaria Policlinico Modena was conducted. We used the statistical approach elsewhere described ([López-Lozano JM, et al. Nat Microbiol.1160–1172, 2019]) to adjust a non-linear model (Multivariate Adaptive Regression Splines) for the identification of possible thresholds. Moreover, a counterfactual analysis to quantify the effectiveness of the different interventions was carried out.

Results: We fit a NL-TSA model (adjusted-R²=0.539) with a threshold at 26.65 litres/1000 bed-days for alcoholic gel consumption (ALCBED) and 58 DDD/1000 bed-days of Carbapenems (CarbUse). An increase by one litre/1000 OBDs of alcoholic gel decreased Di_PaCRE by 0.01 new cases per 1000 OBDs up till a ceiling of 26.65 litres/1000 OBDs. In contrast, the Di_PaCRE increased by 0.04 new cases by 1000 OBDs per one DDD/1000 OBDs of Carbapenems, but only above 58 DDD/1000 OBDs of Carbapenems. The counterfactual analysis of the iCARBA Campaign alone revealed an average monthly decrease in Di_PaCRE of 0.053 (0.029, 0.072, CI-95%) per 1000 OBDs, a total effect 3.19. In addition, we estimated that the iHAND campaign average monthly reduced Di_PaCRE in 0.057 (0.036, 0.079, CI-95%) cases per 1,000 bed-days, a total accumulated decrease of 4.37. Combining all campaigns, we estimate an average monthly decrease by 0.16 (0.13,0.19, CI-95%), with 12.11 of total effect.

Conclusions: A significant reduction of PaCRE was obtained by the implementation of a multifaceted approach, including hand hygiene and ABS aimed to reduce nosocomial transmission and selective pressure. ASP strategies rather than hand hygiene campaigns was associated with a major reduction in PaCRE infections. PaCRE could be controlled by reducing the use of carbapenems below minimum thresholds of 58 DDD/1000 bed-days. This finding could provide an innovative approach to guide ABS strategy.

**Abstract 4285**

**Surveillance of central venous catheter bloodstream infections in critical care units in England: April 2017-March 2019**

Sarah Gerver*, Asad Zaidi¹, Peter Wilson¹, Russell Hope¹

¹Public Health England, London, United Kingdom, ²University College London Hospital NHS Trust, London, United Kingdom

**Background:** Bloodstream infections (BSI) from central venous catheters (CVC-BSI) in critically ill patients in intensive care units (ICUs) increase morbidity and mortality, have high economic impact and are potentially preventable. Substantial reductions in CVC-BSI rates have previously been reported in England in a two-year study (2009-11). A key outcome was the need for a professionally-owned, standardised, national infection surveillance programme in ICUs. Here we present the results from years two and three of the English ICU CVC-BSI surveillance programme.

**Materials/methods:** An online data capture system (DCS) was launched in May 2016 to collect patient-level data on all positive blood cultures (PBCs) in participating ICUs and unit-level data on bed-days and CVC-days. All ICUs in England were invited to participate in the voluntary surveillance programme.

**Results:** By 30/03/2019, 262 ICUs in England had registered on the DCS. For financial years (FY) 2017/18-2018/19, 110 ICUs provided data (99 adult, 5 paediatric, 6 neonatal), entering a total of 6,144, 136 and 296 PBCs, respectively. Of these, approximately half were coagulase-negative staphylococci (adult:44.4%, paediatric:55.9%, neonatal:56.4%). Among PBCs, between 25%-39% were defined as ICU-associated BSI (occurring >2 days after ICU admission, adult: n=2,312/6,144, paediatric: n=53/136, neonatal: n=76/296). Among adult ICUs, 29.5% of ICU-associated BSIs were reported as CVC-BSI (n=682/2,312), this was 39.6% among paediatric ICUs (n=21/53) and 56.6% among neonatal ICUs (n=43/76). Overall, these equate to rates of 2.2, 1.6 and 2.3 per 1,000 ICU-CVC-days, respectively. However, there was wide variation in CVC-BSI rates within ICU types, particularly in adult ICUs (0.0-30.3 ICU-associated CVC-BSI per 1,000 ICU-CVC-days).

**Conclusions:** The overall rates of microbiologically confirmed ICU-associated CVC-BSI are moderate across all age-ranges; however, the difference in rates between units highlights the importance of providing a national standardised surveillance system for benchmarking and to determine the underlying causes. With the surveillance scheme now established, linkage with antimicrobial susceptibility testing data will occur to provide enhanced epidemiological data on antimicrobial resistance patterns within ICUs in England. Furthermore, the use of data linkage with other clinical datasets to reduce the burden of data collection and thereby increase surveillance ascertainment is under investigation.

Abstract 4290

An antibiotic stewardship intervention in the emergency department leads to improved antibiotic prescription especially during normal working hours and among younger faculty

Michaela Demichel1, Sophia Horster1, Jette Jung2, Alexandra Weber1, Andreas Lechner1, Rika Draenert*3

1Ludwig-Maximilians-Universität, Klinikum der Universität München, München, Germany, 2Ludwig-Maximilians-Universität, Max von Pettenkofer Institut, München, Germany, 3Ludwig-Maximilians-Universität, Klinikum der Universität München, München, Germany

Background: Antibiotics are among the most commonly prescribed classes of drugs in emergency departments (ED). In most EDs, high patient numbers and time pressure in combination with often seriously ill patients lead to an overprescribing of broad-spectrum antibiotics. However, the decision of the type of antibiotic in the ED is crucial as it is usually continued on the wards and is not re-evaluated when patients are discharged from the ED. Here we analysed the effect of an antibiotic stewardship intervention in our main ED.

Materials/methods: The antibiotic stewardship intervention consisted of the development of local treatment guidelines for common infections in the ED, training sessions and distribution as posters and pocket cards. Retrospective evaluation of the antibiotic prescription behaviour was performed for periods before and after the intervention. Overall 585 patients were included with one of the following diagnoses: community acquired pneumonia (CAP), pyelonephritis and cystitis. Parameters assessed were (among others): choice of drug, timepoint of treatment in the ED, status of medical training, medical specialty and Charlston Comorbidity index for disease severity. In addition, antibiotic consumption (expressed as DDD/100 patient days) was assessed for both study periods.

Results: The antibiotic stewardship intervention led to a statistically significant improvement of choice of antibiotic drug in the ED. This was shown for all patients (correct antibiotic in 47% of cases before the intervention and in 58.6% of cases after the intervention; p=0.011) and especially for the entity of CAP (30% compared to 64.6%; p=0.0002). Prescribing improved significantly during normal working hours (Monday to Friday 8 a.m. till 5 p.m.) (39.1% compared to 59.8%; p=0.006), in the group of interns and residents (47.6% versus 60%; p=0.036) and for internists (47.7% versus 62.7%; p=0.0015) and neurologists (10% compared to 41.2%; p=0.027). Overall antibiotic consumption decreased by 9%. The use of narrow spectrum penicillins increased (by 34%) whereas the consumption of broad-spectrum penicillins, cephalosporins and fluorchinolones decreased.

Conclusions: The antibiotic stewardship intervention was successful, especially with regard to CAP, antibiotic prescription within normal working hours and among younger faculty. However, implementation and sustainability of behaviour change remain a constant challenge.

In vitro activity of ceftaroline and comparators against Staphylococcus aureus clinical isolates from a tertiary hospital in Greece

Areti Tychala1,2, Maria Arhonti2, Fotini Netsika2, Georgios Meletis2, Paraskevi Mantzana1, Olga Vasilaki2, Georgia Kagkalou2, Efthymia Protonotariou2, Lemonia Skoura2

1Thessaloniki Psychiatric Hospital, Stavroupoli, Greece; 2AHEPA University Hospital, Department of Micorbiology, Thessaloniki, Greece

Background: Ceftaroline is a new parenteral cephalosporin with bactericidal activity against serious infections caused by Gram-positive bacteria including methicillin-resistant S. aureus (MRSA). The aim of our study was to assess the in vitro activity of ceftaroline and comparators against S. aureus (SA) clinical isolates.

Materials/methods: From 7/2017 to 11/2019, 488 SA isolates were recovered from patients hospitalized in several departments of AHEPA University Hospital. 236 of them were MRSA (48.36%) and 252 methicillin-susceptible (MSSA) (51.64%). The strains were isolated from various clinical sites including blood, urine, tracheobronchial secretions, intravenous catheters, fluids and wound samples. Bacterial identification and antimicrobial susceptibility testing were performed using the Vitek2 automated system (bioMérieux, France). MIC50 and MIC90 were calculated for each antimicrobial and interpreted using the current EUCAST guidelines. Due to lack of clinical data, a strain was considered resistant to ceftaroline when the MIC was > 2 mg/L, as suggested by EUCAST for indications other than pneumonia.

Results: MIC50, MIC90 and susceptibility rates of the studied isolates are shown on the Table below. Ceftaroline showed potent antimicrobial activity against SA with MIC50/90 values being 0.5/1 mg/L for MRSA and 0.25/0.25 mg/L for MSSA. Three (3) MRSA isolates exhibited MIC = 2 mg/L to ceftaroline. Levofloxacin, moxifloxacin, clindamycin and erythromycin had the lowest activity against MRSA with susceptibility rates of 22%, 21%, 28% and 23% respectively. All antimicrobials appear to be highly active in vitro against MSSA isolates, with susceptibility rates ranging from 78% to 100%.

Conclusions: Overall, ceftaroline showed excellent in vitro activity against the tested SA isolates along with other comparators in our hospital. Therefore, it could be used as an alternative for the treatment of serious infections caused by these strains.

Universal neonatal screening for congenital cytomegalovirus, the time is now?
Jos Van Acker*1, Elke Vanlaere1, Anne-Marie Van Den Abeele1, Veerle Staelens2, Inge Dierickx3,4, Charlotte Verfaillie1
1Algemeen Ziekenhuis St-Lucas, Laboratory of Clinical Microbiology, Gent, Belgium, 2Algemeen Ziekenhuis St-Lucas, Department of Pediatrics, Gent, Belgium, 3Algemeen Ziekenhuis St-Lucas, Department of Obstetrics & Gynecology, Gent, Belgium, 4Hasselt University, Department of Physiology, Hasselt, Belgium

Background: We demonstrate the impact on patient care of universal neonatal screening for congenital Cytomegalovirus (cCMV) in our hospital.

Materials/methods: From February 2nd, 2015 onwards, a universal neonatal cCMV screening program was implemented in our Belgian secondary care hospital. At mid pregnancy, parents are informed about the program and possible preventive measures by a leaflet distributed by the gynecologist or midwife. Within 48 hours postpartum, saliva of the newborn is collected by the pediatrician using Eswab (Copan, Italy) and analyzed for CMV DNA by an in house RT-PCR. Positive saliva tests are confirmed by demonstrating CMV presence on a urine sample of the newborn and/or by comparison with CMV serology of the newborn’s mother. Results are analyzed until February 1st 2019.

*symptomatic neonates

Conclusions: Universal neonatal cCMV screening was easily adopted and has become common practice in our hospital with compliance rates of 98.9%. Overall, 130 neonates (1.4%) showed a positive screening result, and in 39 (0.4%) cCMV infection was confirmed. Without the screening program, 30/39 (76.9%) of cCMV cases, 11 of which symptomatic, would not have been detected immediately after birth. Confirmation of positive saliva CMV screening results by analysis of an independent urine sample and/or serology of the mother remains necessary as CMV contamination rate in saliva is high (0.8%).

Evaluation of BD MAX multidrug-resistant tuberculosis assay for detection of Mycobacterium tuberculosis complex in clinical specimens and identification of genetic resistance markers

Sabine Hofmann-Thiel*,1,2, Sara Plesnik1, Mariana Mihalic1, Markus Beutler1, Harald Hoffmann1,2

1Institute of Microbiology and Laboratory Medicine, Department IML red GmbH, WHO-Supranational Reference Laboratory of Tuberculosis, Gauting, Germany, 2SYNLAB Gauting, Medizinisches Versorgungszentrum Humane Genetik, Gauting, Germany

Background: Rapid and accurate diagnosis of tuberculosis (TB) and fast detection of drug resistance are critical for successful TB control strategies. BD MAX multidrug-resistant (MDR) TB (BD MAX) is a new, highly automated molecular assay for rapid detection of Mycobacterium tuberculosis complex (MTBC) directly in clinical specimens and simultaneous identification of genetic markers for resistance towards isoniazid (INH) and rifampicin (RIF). Aim of the present study was to evaluate the diagnostic accuracy of BD MAX for cohorts of MTBC negative, paucibacillary, and multibacillary MTBC positive samples.

Materials/methods: 503 archived respiratory specimens (366 sputa, 137 bronchial aspirates) which had been processed by conventional N-acetyl-L-cysteine/sodium hydroxide method were analyzed by BD MAX in a retrospective case control study. The set of study samples comprised 257 MTBC negative samples (205 culture negative samples, 52 growing non-tuberculous mycobacteria), 93 smear negative and 153 smear positive samples growing MTBC.

Results: Based on culture as method of comparison, the overall sensitivity of BD MAX was 86.6%; the sensitivities for smear positive and smear negative samples were 100% and 64.5%, respectively. The specificity rates were 100% for both culture negative specimens and those which grew non-tuberculous mycobacteria. Sensitivity and specificity for INH resistance compared with phenotypic drug resistance testing were 58.3% and 99.3%, respectively. The five samples being phenotypically resistant to INH but susceptible by BD MAX originated from only two patients. Thus, the low sensitivity of 58.3% is caused, at least in part, by a random effect due to selection of study samples. Sensitivity and specificity for RIF resistance were 100% and 98.2%. When compared to results from Genotype MTBDRplus and Sanger sequencing, sensitivity and specificity rates for INH were 100% and 99.4%, and for RIF 100% and 99.4%.

Conclusions: BD MAX is a sensitive and highly specific assay for the diagnosis of TB and detection of genetic resistance markers. Limitations of the study include the use of frozen samples what may have negatively influenced assay sensitivity.

Abstract 4296

**Rhamnolipid coating reduces formation of *Candida albicans*-Staphylococcus aureus mixed biofilm on titanium implants: an in vitro study**

Erica Tambone¹, Chiara Ceresa³, Devid Maniglio¹, Federico Piccoli³, Iole Caola³, Giandomenico Nollo¹⁴, Paolo Ghensi⁵, Patrizio Caciagli³, Letizia Fracchia², Francesco Tessarolo*¹⁴

¹Department of Industrial Engineering and Biotech Center, University of Trento, Trento, Trento, Italy, ²Department of Pharmaceutical Sciences, Università del Piemonte Orientale "A. Avogadro", Novara, Italy, ³Department of Medicine Laboratory, Azienda Provinciale per i Servizi Sanitari di Trento, Trento, Italy, ⁴Healthcare Research and Innovation Program (IRCS-FBK-PAT), Bruno Kessler Foundation, Trento, Italy, ⁵Center for Integrative Biology, University of Trento, Trento, Italy

**Background:** In recent years, an increased number of implant infections caused by multi-species biofilm has been reported. Within a multi-species biofilm, microorganisms can interact and cooperate with each other, increasing pathogenicity, virulence and resistance to antimicrobial agents of the individual species. New strategies to prevent implant colonization are proposing to coat the surface with antimicrobial and anti-adhesive agents, such as biosurfactants.

This study aimed at assessing the ability of the rhamnolipid R89 biosurfactant (R89BS), deposited on medical-grade titanium, to inhibit formation of *C. albicans*-S. aureus mixed biofilm.

**Materials/methods:** Titanium discs (TDs) were coated with R89BS, while uncoated TDs were used as control. TDs were dipped in 1 mL of the suspension (with a final concentration of 10⁵ CFU/mL for *C. albicans* ATCC 10231 and 10⁷ CFU/mL for *S. aureus* ATCC 6538 in YNBD+10% FBS) and incubated at 37°C at 70 rpm, renewing growth medium every 24h.

The anti-biofilm activity of R89BS-coated TDs was evaluated by quantifying, at 24, 48 and 72h, total biomass (crystal violet staining), cell metabolic activity (MTT assay) and cell viability (cell viable counting). A qualitative analysis of multi-species biofilms on TDs was carried out with scanning electron microscopy.

Data analysis was performed by t-test and statistical significance was considered for p<0.05.

**Results:** *C. albicans*-S. aureus mixed biofilm were mainly composed of fungal cells and resulted significantly inhibited by R89BS coating, with a similar effect on biofilm biomass, cell metabolic activity and viable cell count (Figure 1). A biofilm inhibition up to 96% was observed at 24h. After 48h, a less marked, but still significant inhibition was detected for cell metabolic activity in respect to biofilm biomass and viable cell count. R89BS coating resulted more effective in reducing bacterial cells rather than fungal cells.

**Conclusions:** R89BS coating is effective in reducing *C. albicans*-S. aureus mixed biofilm on titanium surfaces and can be considered as a promising strategy to prevent implants colonization.
Figure 1: Inhibition of C. albicans-S. aureus mixed biofilm biomass (a), cell metabolic activity (b), and cell viability (c) on R89B5-coated TDS, in respect to normalized controls. ***p<0.001, **p<0.01.

Abstract 4298

Effects of spectrum of antibiotics on microbiome compositions and resistome levels
Karen Leth Nielsen*, Markus Harboe Olsen1, Albert Palleja2, Søren Reddik Ebdrup1, Nikolaj Sørensen2, Oksana Lukjancenko2, Rasmus Marvig1, Kirsten Møller1, Niels Frimodt-Moller1, Frederik B. Hertz1,3

1Rigshospitalet, København, Denmark, 2Clinical-Microbiomics A/S, København, Denmark, 3Slagelse Sygehus, Slagelse, Denmark

Background: Long-term hospitalization and treatment with antibiotics increase the risk of acquiring multidrug-resistant bacteria due to antibiotic-mediated microbial compositional shifts. This study aimed to investigate how different antibiotics affect the gut microbiome and the resistome in antibiotic naïve patients during neurointensive care.

Materials/methods: Forty patients admitted to neurointensive care unit of Rigshospitalet, Copenhagen, Denmark were treated with broad-spectrum (meropenem or piperacillin/tazo-bactam) or more specific antibiotic treatment (including ciprofloxacin, cefuroxime, vancomycin and dicloxacillin). A rectal swab was collected from each patient before and after 5-7 days of antibiotic therapy. Shotgun metagenomic sequencing was performed and composition of metagenomic species (MGS) were determined. The resistome (as collection of antibiotic resistance genes) was characterized with CARD RGI software and CARD database. As a measure for selection pressure in the patient, we used the parameter antibiotic days (∑ number of days with each antibiotic). Groups were compared with Wilcoxon signed-ranked tests.

Results: The MGS composition of the microbiome changed independent of applied antibiotic treatment. We observed an increase in diversity in patients receiving more narrow-spectrum treatment (p = 0.016) and we observed two populations among the broad-spectrum patients; some decreased in diversity and some increased. We compared patients that had gained or lost >10 species, respectively. Antibiotic days were significantly higher in patients with decreased richness (p = 0.0054) and decreased Shannon diversity (p = 0.012), and these patients received a higher number of antibiotics (richness: p = 0.063; for Shannon index: p = 0.086). Changes in resistome followed MGS composition and was independent of administered antibiotics. We observed a higher prevalence of vancomycin resistance genes in post-treatment patients (p = 0.019).

Conclusions: Antibiotic spectrum was not found to have notable differential effects on the MGS composition or resistome of the microbiome. However, we observed a significantly higher number of vancomycin resistance genes after treatment. Patients who received narrow-spectrum treatment exhibited an increase in diversity. Selection pressure (antibiotic days) was found to be higher in patients with a decreased MGS diversity. The selection pressure in the patient may be a better predictor of the effect on the microbiome than the spectrum of the antibiotics.

Julie Figoni*, Lucie Fournier, Elodie Moutengou, Alexandra Septfons, Camille Bonnet, Henriette De Valk, Benoit Jaulhac, Thierry Blanchon

1Santé publique France, Saint-Maurice, France, 2Sorbonne Université, INSERM, Institut Pierre Louis d’Épidémiologie et de Santé Publique [IPLESP UMRS 1136], Paris, France, 3National Reference center for Borrelia, University of Strasbourg and CHRU Strasbourg, Fédération de Médecine Translationnelle de Strasbourg, EA7290 Lyme borreliosis group, Institut de Bactériologie, Strasbourg, France

Background: Lyme borreliosis (LB) is the most frequent vector-borne disease in France. Since 2009, its surveillance is based on a sentinel network of general practitioners (Sentinelles network - SGPs) completed with the surveillance of hospitalized LB cases using the national hospitalization database available from 2005. We describe surveillance data in order to estimate incidence, detect trends and identify risk groups and high-incidence regions.

Materials/methods: SGPs report new diagnoses of LB. Reported cases are validated applying the European Union Concerted Action on LB case definitions. A hospitalized LB case was a person hospitalized with a LB specific diagnosis (ICD10 codes: M01.2 or L90.4 or A69.2 in the absence of any other diagnosis or associated with code(s) compatible with LB symptoms {neurological, cardiac, articular, ocular disorders}).

Results: From 2009 to 2018, the mean yearly incidence rate of patients consulting a GP for LB was 58 cases per 100,000 inhabitants fluctuating between 41 in 2011 and 104 in 2018. In 2016 and 2018, significant increases in LB incidence were observed. The hospitalization incidence rate (HIR) increased from 1.1 cases per 100,000 inhabitants in 2005 to 1.5 in 2018 with significant trend over the period. However, the significant peaks of 2016 and 2018 observed in general practice were not observed in our hospital based surveillance. Same significant inter-regional variations were observed in both data sources. HIR peaked in 5-9 and 70-79 years old. The incidence rate of LB diagnosed at GP level peaked in 60-69 years old. Erythema migrans affected 95% of the cases at primary care level. Among hospitalized cases, the most common manifestation was neuroborreliosis with a mean of 440 cases/year (52%). Among neuroborreliosis hospitalized cases, 36% presented with facial nerve disorders.

Conclusions: These data allow to follow general trends and can be used to target public health strategies towards the high risk groups for LB and neuroborreliosis. If there is an increase of the disease incidence in France over the last years that could be explained by recent modifications of ticks’ ecology, the improved awareness towards the disease could have also participated in the recent peaks in 2016 and 2018.

Abstract 4300

**When cold water is too warm: healthcare-associated Legionnaires’ disease associated with hot season**

Frederike Waldeck*, Philipp Patrick Kohler, Manuel Frischknecht, Rolf Kuhn, Matthias Von Kietzell, Werner Albrich, Matthias Schlegel

1Cantonal Hospital of St. Gallen, Department of infectious diseases and hospital epidemiology, St. Gallen, Switzerland

**Background:** The most common form of legionellosis is pneumonia which can be acquired by inhalation of aerosolized *Legionella* spp. most commonly from man-made water-bearing systems. *Legionella* spp. grows best at 25 – 45°C. Increasing numbers of health-care associated legionella pneumonia have been observed in our hospital region since 05/2018 which led to this epidemiologic investigation. The aim was to prevent further cases.

**Materials/methods:** Sampling of the hot and cold water reservoir of two adjacent hospital water systems was performed. Samples were incubated and concentration of *Legionella* determined. The Swiss Federal Office of Public Health defines a *Legionella* concentration of ≥100 cfu/ml as elevated in high-risk settings such as oncological wards or intensive care units, where temperature has to be <25°C in cold water and >55°C in hot water. Technical details of the water supply system were inspected including presence of inactive and unused pipes, water flow in pipes, water temperatures at exit sites and in reservoir.

**Results:** We observed six cases of health-care associated legionellosis from 05/2018 – 09/2019. Concentrations of *Legionella* ≥100 cfu/ml were demonstrated in hot and surprisingly also in cold water in both hospitals and were significantly associated with temperatures above and below those recommended in cold and hot water system (p=0.004; odds ratio 27.0 [95% confidence interval 2.5 – 284.7]). Construction work involving the water supply caused inactivation of pipes and stagnation in the hot water supply. Elevated temperatures in the cold water supply were observed during hot season and construction work. Preventive measures included daily flushing of all pipes, installation of *Legionella* filters in showers, heating up and chlorination of the hot water supply and reconstruction of the cold water system. No subsequent cases of Legionnaire’s disease were observed.

**Conclusions:** While *Legionella* are commonly found in not sufficiently hot water reservoirs, our outbreak investigation identified also an association of increased legionella concentrations with too warm cold water supplies. These occurred during the hot season and construction work affecting the water system and could be reversed with preventive measures. Cold water supply must be considered as a possible source of Legionnaire’s disease.

**Presenter email address:** frederike.waldeck@kssg.ch
Abstract 4302

In vitro activity of ceftolozane-tazobactam and comparators against beta-lactam-resistant pathogens isolates collected from patients with urinary tract, intra-abdominal and lower respiratory infections in Lebanon and Jordan [SMART Study Data 2016-2017]

Aline Hajj1,2, Tarek Itani*3, Wail Hayajneh4, Andre Adame1, Noha Hakime5, May Mallah Hamdan1, Jihane Maalouf7, Reema Alsamarneh5, Mary Motyl8, Dan Sahm9, Irina Alekseeva10, Dolla Karam Sarkis1

1Laboratoire de Pharmacologie, Pharmacie Clinique et Contrôle de Qualité des Médicaments, Saint-Joseph University, Beirut, Lebanon, 2Faculty of Pharmacy, Saint-Joseph University, Beirut, Lebanon, 3Molecular Microbiology Laboratory, Saint-Joseph University, Beirut, Lebanon, 4Faculty of Medicine, Jordan University of Science and Technology, Irbid, Jordan, 5Department of Clinical Laboratory, Saint George Hospital, University Medical Center, Beirut, Lebanon, 6MSD Idea GmbH, Beirut, Lebanon, 7Laboratory Department, King Abdullah University Hospital, Irbid, Jordan, 8International Health Management Associates, Inc, Schaumburg, United States, 9International Health Management Associates, Inc., Schaumburg, United States, 10MSD Idea GmbH, Dubai, United Arab Emirates

Background: The Study for Monitoring Antimicrobial Resistance Trends (SMART) has been tracking resistance among Gram-negative bacilli (GNB) since 2002. High resistance rates over the years required the use of novel beta-lactam combination agents such as ceftolozane-tazobactam. This report summarizes the susceptibility rates to ceftolozane-tazobactam versus comparators and molecular characterization of extended spectrum beta-lactamases (ESBL)- and carbapenemases producing isolates collected from patients with urinary tract (UTI), intra-abdominal (IAI) and lower respiratory tract (LRTI) infections in Lebanon and Jordan (2016-2017).

Materials/methods: 332 ESBL-producing enterobacteriaceae were collected from four centers in Lebanon (131, n=2) and Jordan (201, n=2). The isolates were then shipped to a central laboratory (IHMA, Switzerland) to confirm the identification and susceptibility testing results and perform the molecular characterization. Extended spectrum beta-lactamases (ESBLs) and carbapenemases were characterized using the Check-Points microarray, followed by PCR and sequencing. We characterized all enterobacteriaceae isolates that were non-susceptible to ertapenem (CLSI breakpoints), and 50% (due to cost constraints) of the isolates that were phenotypically ESBL-positive but ertapenem susceptible.

Results: In general, Lebanese isolates exhibited relatively high susceptibility rates to ceftolozane-tazobactam (92%, 86.7%, and 88.5% in UTI, IAI, and LRTI respectively), while susceptibility rates to other beta-lactams (except for carbapenems) were notably lower (Figure 1). Lower susceptibility rates could be noted in Jordan including to ceftolozane-tazobactam with susceptibility rates of 88.8% (UTI), 77.4% (IAI), and 55.9% (LRTI). Low susceptibility levels to carbapenems were also noted in LRTI from Jordan compared to Lebanon (57.6% versus 92.3% to ertapenem, 78% versus 96.2% to imipenem and 81.4% versus 96.2% to meropenem). The high resistance rates in Jordan could be explained among others by the emergence of carbapenemases such as blaOXA-type: 30 strains isolated in LRTI, 17 in IAI and 5 in UTI versus only 8 strains in Lebanon (all sources). The most prevalent carbapenemases remain blaOXA-48 and blaOXA-181.

Conclusions: These findings highlight the importance of this novel antibiotic in treating complicated infections caused by ESBL producing enterobacteriaceae, especially in Lebanon but not for empiric use for LRTI in Jordan. Nevertheless, the result underscore the importance of appropriate antimicrobial stewardship strategies that are urgently needed in Jordan in order to control the growth of the problem of resistance.
LEBANON-JORDAN: SMART DATA 2016-2017:
Susceptibility rates of ESBL-producing pathogens in (A): IA, (B): LRTI and (C): UTI and (D): Molecular data of carbapenemases.

Abstract 4306

Revision of clinical guidelines for hospital-acquired pneumonia led to a reduction in carabapenem prescriptions at a Swiss cantonal hospital

Fabian Schefer1, Thomas Fehr1, Felix Fleisch1, Alexia Cusini*

1Cantonal Hospital of Grisons, Chur, Switzerland

Background: Carbapenems were replaced with cefepime or piperacillin/tazobactam in our internal guidelines for empiric treatment of late onset hospital acquired pneumonia (HAP) in May 2016. The recommendation for amoxicillin/clavulanate in early onset HAP remained unchanged. Antibiotic prescribing practice was assessed before and after guideline change.

Materials/methods: Electronic records of in-patients with a clinical diagnosis of HAP, extending 18 months before (period I) and after (period II) the guideline change, were retrospectively evaluated. Clinical data and antibiotic prescriptions were recorded. Differences in antibiotic prescriptions were analysed with Fisher’s exact test.

Results: 82 patients in period I and 86 in period II were included in the analysis. Median patient age was 77 years in period I and 74 in period II. Median Charlson Comorbidity index was 4.9 in both groups. Despite treatment prescription for a diagnosis of HAP, all criteria meeting the strict HAP definition (respiratory symptoms, new radiologic findings and signs of systemic inflammation) were retrospectively fulfilled in only 59% and 48% of patients in periods I and II respectively. Empiric guideline adherence was 84% in period I and 75% in period II. Prescription of imipenem/cilastatin decreased from 40% in period I to 6% in period II (p < 0.001), use of piperacillin/tazobactam increased from 32% to 45% (p = 0.082) and use of amoxicillin/clavulanate increased from 22% to 34% (p = 0.121). Cefepime prescription increased from zero in period I to 6% in period II (p = 0.059). Treatment duration was longer than recommended in 13% of patients in period I and 8% in period II. Treatment was successful in 86% of patients in period I and 89% in period II.

Conclusions: A safe and substantial reduction in empiric use of carbapenems for presumed HAP was achieved through guideline change. Appropriate diagnosis and indication for treatment of HAP remain challenging.

Abstract 4307

Performance of RealAccurate Quadruplex Mycobacteria PCR for detection of non-tuberculous mycobacteria in clinical samples

Jasmine Coppens*1, Sam Van Goethem1, Kristof Berge1, Mindy Mihiels1, Leen Rigouts1, Herman Goossens1, Hilde Jansens1, Veerle Matheussen2

1Antwerp University Hospital, Edegem, Belgium, 2Institute of Tropical Medicine Antwerp, Mycobacteriology Unit, Department of Biomedical Sciences, Antwerpen, Belgium

Background: Simultaneous molecular detection of non-tuberculous mycobacteria (NTM) next to Mycobacterium tuberculosis complex (MTB) might be beneficial in routine microbiological practice as NTM infections are not always considered. This feature is offered by the RealAccurate Quadruplex Mycobacteria PCR kit (PathoFinder) but performance data are scarce. Our study aimed to evaluate this commercial assay specifically for NTM detection in clinical samples.

Materials/methods: The Pathofinder assay was used for MTB detection in clinical samples from patients at the Antwerp University Hospital during 2018-2019. DNA was extracted with NucliSENS® easyMAG® (bioMérieux) and amplified using the RealAccurate Quadruplex Mycobacteria PCR kit (PathoFinder) on LightCycler® 480 (Roche). Samples positive for NTM or with clinical suspicion of NTM infection (n=38; 15 respiratory samples, 10 biopsy, 8 glands, 3 pus/fluid and 2 CSF) were also analysed by culture (n=30) and/or an in-house conventional nested PCR (n=38) (reference method). Proficiency testing for NTM was performed on the 2019 NTM QCMD panel (n=10).

Results: An agreement of 100% was achieved with the Pathofinder on the proficiency panel. Of the 38 clinical samples, 26 were NTM positive by Pathofinder (Ct-values: 29.29-38.14). However only 7 of these (Ct-values: 29.29-37.7) were positive with the reference method (1 via culture, 7 via PCR). For the 19 false-positive samples (Ct-values: 33.3-38.14) NTM infection was also not suspected based on clinical evaluation and culture data. Twelve of the 38 samples were NTM negative with Pathofinder, but 3 of those were positive with the reference method (1 via culture, 3 via PCR). The treating physicians considered all 3 patients as real NTM infected and patients were successfully treated. Neither false-positive nor false-negative results could be allocated to certain sample types. A sensitivity of 70% (95%CI: 35-93%) and specificity of 32% (95%CI: 16-52%) was obtained.

Conclusions: The Pathofinder assay showed low sensitivity and poor specificity for NTM detection in clinical samples although proficiency testing results were excellent. Aspecific amplification did not result in higher Ct-values or in differently shaped amplification curves compared to real positive results and could therefore not be distinguished. We do not recommend to use the assay for NTM detection in routine practice.

Abstract 4309

Modelling the impact of antibiotic resistance on surgical site infections: the case of hip replacements
Stephanie Evans*1, Nichola Naylor2, Koen Pouwels3, Theresa Lamagni1, Kristine Cooper1, Berit Muller-Pebody1, Julie Robotham1

1Public Health England, London, United Kingdom, 2Imperial College London, National Institute for Health Research Health Protection Research Unit in Healthcare Associated Infection and Antimicrobial Resistance, London, United Kingdom, 3University of Oxford, Oxford, United Kingdom

Background: Potential consequences of increased antibiotic resistance (ABR) include not only the increased risk of untreatable infections but also the largely unquantified effect of jeopardising the safety of surgeries reliant on antibiotic prophylaxis. Hip replacements account for approximately 30% of surgeries in England, and with antibiotic prophylaxis they have a low risk of surgical site infection (SSI). Consequently, they provide an ideal case study for evaluating the impact of a reduction in efficacy of antibiotic prophylaxis due to resistance. We present a model utilising English national surveillance data to estimate the potential burden of ABR on SSIs and apply it to the case of hip replacement surgery.

Materials/methods: Commonly used prophylactic antibiotics were identified from hospital prescribing guidelines/literature. To estimate the current prevalence of ABR, the proportion of hip swab samples from 2016-2018 that contained bacteria that were resistant to antibiotics commonly used for prophylaxis were estimated from English surveillance data using bootstrapping. The increase in infections resulting from varying levels of reduction in efficacy of prophylaxis was estimated by calculating the attributable risk reduction of infection between prophylaxis and control groups. A 100% reduction in efficacy was assumed to be the infection rate observed in the control group, derived from historical clinical trials of antibiotic prophylaxis versus placebo and groups at high risk of prophylaxis failure due to factors including obesity and diabetes in more recent published studies. We estimated this value to be in the range of 2-6%.

Results: Approximately 11% of SSIs following hip replacement surgeries were resistant to commonly used prophylactic antibiotics. Preliminary predictions estimate that, under current prophylaxis guidelines, ABR could cause up to a 10-fold increase in infections resulting from hip replacement surgery in England (Figure 1).

Conclusions: There is potential for increasing rates of ABR to considerably impact SSI incidence following hip replacement surgery, which has not previously been quantified in the European setting. Adequately defining the population that are susceptible and resistant to prophylaxis is crucial to producing accurate predictions of future impact.

Figure 1: Expected increase in infections per year resulting from hip replacement surgery at different levels of resistance

Background: Lactic acidosis is one of the most fatal adverse effects of linezolid, an antibiotic used to treat serious infections caused by antibiotic-resistant bacteria. However, the measures to prevent lactic acidosis have not been well established. We performed a retrospective study to analyze the impact of applying a serum lactate monitoring recommendation policy in patients treated with linezolid.

Materials/methods: Since September 2011, we have recommended inpatient monitoring of serum lactate levels in patients treated with linezolid at our hospital. Patients were divided into two groups according to whether they were seen during the non-recommendation or recommendation periods. The frequency of serum lactate monitoring, linezolid-induced lactatemia, lactic acidosis, critical illness, and death were compared between the two periods.

Results: After September 2011, adherence to the recommendation to monitor serum lactate increased from 6.1% to 60.1%. No difference was observed in the incidence of linezolid-induced lactatemia and lactic acidosis between the two periods. However, there was a significant difference in the incidence of linezolid-induced critical illness between the non-recommendation and recommendation periods (3 vs 0 cases, \( p = 0.044 \)).

*Critical illness includes shock, hemodialysis, and death

Conclusions: In patients treated with linezolid, serum lactate monitoring led to early detection of lactatemia, thus enabling rapid rescue. We recommend regular monitoring of serum lactate in all patients treated with linezolid.

Isavuconazole for the treatment of invasive fungal infection in solid organ transplant recipients: experience from a referral centre

María Ruiz-Ruigómez*, Laura Corbella Vazquez, Isabel Rodríguez Goncer, Jose Tiago Sequeira, María Pilar Hernandez Jimenez, Francisco Lopez-Medrano, Rafael San Juan Garrido, Jose M. Aguado Garcia, Mario Fernandez Ruiz

1Unit of Infectious Diseases. University Hospital 12 de Octubre, Instituto de Investigación Hospital "12 de Octubre" [imas12], Madrid, Spain, 2Hospital Universitario "12 de Octubre", Instituto de Investigación Sanitaria Hospital "12 de Octubre" [imas12], Unit of Infectious Diseases, Madrid, Spain

Background: Invasive fungal infection (IFI) is a major complication after solid organ transplantation (SOT). Interactions with immunosuppressive agents and increased risk of azole-induced toxicity complicate treatment of post-transplant IFI. Isavuconazole (ISA) is a broad-spectrum triazole with pharmacokinetic advantages and low potential for drug-to-drug interactions. However, SOT recipients were underrepresented in pivotal trials, and real-world data on the safety and efficacy of ISA in this population are scarce.

Materials/methods: We reviewed all SOT recipients with a diagnosis of IFI according to EORTC criteria that received ISA as first-line or salvage therapy at our institution from January 2018 to October 2019.

Results: We included 14 patients: 4 kidney (28.6%), 4 heart (28.6%), 3 lung (21.4%), 2 small bowel (14.3%), and one kidney-pancreas recipient (7.1%). Median interval from transplantation to IFI diagnosis was 121 days (IQR: 71.8 – 744.3). One patient (7.1%) met criteria for possible, 8 (57.1%) for probable and 5 (35.7%) for proven IFI. Aspergillus spp. was isolated in 13 patients (A. fumigatus [8 cases], mixed infection involving A. fumigatus [2 cases], and A. lentulus, A. nidulans, A. granulosus [one case each]). Sites of infection included invasive pulmonary aspergillosis (57.1% [8/14]), isolated CNS aspergillosis (14.3% [2/14]), disseminated aspergillosis, cutaneous aspergillosis, tracheobronchial aspergillosis, and disseminated IFI due to Trichosporum inkin (7.1% [1/14] each). ISA was used as first-line therapy in 12 patients (85.7%); the remaining 2 were switched to ISA due to voriconazole-induced hepatotoxicity or drug interactions. Combination therapy (mainly with an echinocandin) was used in 7 patients (50.0%). Tacrolimus daily dose was reduced in 9 (64.3%) patients by a median of 47%, with no differences observed in blood trough levels during the first month of therapy. Complete and partial response rates were 58.3% [7/12] and 41.7% [5/12] among evaluable patients. Treatment-emergent adverse events attributable to ISA occurred in one patient (7.1%) with electrolyte imbalance that resolved after discontinuation of therapy. Among 9 patients with serial ECG recordings, 4 (44.4%) had cQT interval shortening (median of 30 mseg). There was one death (7.1%) during follow-up not attributable to IFI.

Conclusions: ISA appears to be effective and well tolerated in SOT recipients with IFI.

Abstract 4314

**Experimental evolution of high-level azithromycin resistance in Neisseria gonorrhoeae during morbidostat culture**

Jolein Laumen*, Sheeba S. Manoharan-Basil, Els Verhoeven, Said Abdellati, Iriith De Baetselier, Tania Crucitti, Basil Britto Xavier, Sabine Chapelée, Christine Lammens, Christophe Van Dijck, Surbhi Malhotra-Kumar, Chris Kenyon

1Institute of Tropical Medicine, Department of Clinical Sciences, STI unit, Antwerpen, Belgium, 2Institute of Tropical Medicine, Department of Clinical Sciences, STI Reference Laboratory, Antwerpen, Belgium, 3Cente Pasteur du Cameroun, Yaoundé, Cameroon, 4University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious disease institute, Antwerpen, Belgium, 5University of Cape Town, Department of Medicine, Cape Town, South Africa

**Background:** The prevalence of azithromycin resistance in Neisseria gonorrhoeae (NG) now exceeds 5% in multiple locations around the world. We sought to characterize the genetic pathway to high-level azithromycin resistance (HL-AZMR: minimal inhibitory concentration (MIC) >256mg/L).

**Materials/methods:** A NG-morbidostat was constructed and used to subject two NG reference strains (WHO-F and WHO-X) to dynamically sustained AZM pressure. Experiments were performed in triplicate (F1 -F3, X1 -X3) and included controls that received no AZM. Cultures were sampled twice a week and MICs of azithromycin were determined using E-test (bioMérieux). Whole-genome sequencing (WGS) was performed using MiSeq (Illumina) via 2x 250b reads (Nextera XT). Reads were processed and mapped to the WHO reference genomes [LT51957 and LT519215] followed by variant analysis using CLC Genomics Workbench v 12.0.

**Results:** Within four weeks, all cultures evolved to HL-AZMR. One strain of WHO-F and all triplicates of WHO-X developed high-level resistance between day 13 and 17 (Figure 1). HL-AZMR was attained by day 24-26 in the other two strains of WHO-F. WGS revealed variants associated with low-to-mid level resistance in several genes. In the case of rplD, rplIV, mtrD and recJ, the same, or similar mutations were found in different vials. Nonsynonymous mutations in the 50S ribosomal proteins L4 (rplD) and L22 (rplIV) included G70D and R71C for L4, and a F85S and deletion of codons at 94-97 positions for L22. K823E and A443V substitutions were observed in the mtrD and the recJ gene, respectively. Variants in the pilQ and topB genes were only detected in one vial each, F1 and F3. When MICs shifted to high-level resistance, three mutations at the 23S ribosomal RNA were observed. The well-known A2059G mutations was observed in most vials. Whereas, F3 showed a mutation at position 2058 and X2 at position 2611. The controls for both WHO strains retained their low MICs.

**Conclusions:** These data show that development of low and mid-level AZMR was mainly associated with mutations in genes encoding the multidrug efflux mtrD subunit, the recJ exonuclease and the ribosomal proteins L4 and L22. High level resistance was only achieved by point mutations in the 23S rRNA.

**Abstract 4316**

**Influenza and respiratory syncytial virus antigen diagnostic tests: do they still have a place in a routine diagnostic laboratory?**

Ben Vanmassenhove*,1, Anne-Sophie Hervent1, Lies Persijn1, Liesbeth Vynckier1, Gudrun Alliet1

1AZ Damiaan, Oostende, Belgium

**Background:** Rapid diagnosis of respiratory infections can help clinical decision making easier leading to a reduction of unnecessary antibiotic use and a reduction of nosocomial infections by means of isolation procedures.

Antigen testing is a cheap method which is easy to perform and the result is obtained after only 15 minutes but the sensitivity is variable.

**Materials/methods:** The antigen detection tests were done following the manufacturers’ instructions (BinaxNOW® Influenza A &B and RSV [respiratory syncytial virus] Card - Alere/Abbott) and results were compared with an in-house RT-PCR test targeting the M-gene [matrix] for influenza and the N-gene [nucleoprotein] for RSV. Retrospective evaluation was done on data collected during five winter seasons [2014-2019] in a Belgian regional hospital. Sensitivity was compared between a pediatric and an adult population (> 16 years).

**Results:** The average sensitivity of the RSV antigen test in the pediatric population (1607 patients) was 63% which stayed more or less constant over the five seasons.

The average sensitivity of the influenza antigen test in the pediatric population (1438 patients) was almost two times higher than the sensitivity in the adult population (1262 patients): 58% versus 32%.

The sensitivity of the influenza antigen test ranged from 53 to 73% in the pediatric population and from 19 to 37% in the adult population, depending on the subtype of the influenza strains which were circulating in that particular winter season.

**Conclusions:** Our evaluation is in line with the literature (C. Chartrand et al., Ann Intern Med, 2012).

According to our opinion a cheap rapid antigen test can be performed as a first line analysis in the pediatric population when a negative result is followed by a molecular diagnostic test. In the adult population however a rapid antigen test should not be used in routine due to a lack of sensitivity and a molecular diagnostic test is the preferred method of choice.

Abstract 4317

Whole metagenome shotgun-sequencing in a case of hyperammonaemia syndrome following lung transplantation
Charlotte Michel*1, Vladimir Lazarevic2, Nina Leduc3, Michela Raimo4, Christiane Knoop3, Jacques Schrenzel2, Marie Hallin1, Maya Hites4, David Grimaldi5

1Department of Microbiology, Laboratoire Hospitalier Universitaire de Bruxelles (LHUB-ULB), Bruxelles, Belgium, 2Geneva University Hospitals, Geneva, Switzerland, 3Department of Pneumology, CUB-Erasme Hospital, Brussels, Belgium, 4Department of Infectious diseases, CUB-Erasme Hospital, Brussels, Belgium, 5Intensive Care Unit, CUB-Erasme Hospital, Brussels, Belgium

Abstract third-party references: Department of Microbiology, Laboratoire Hospitalier Universitaire de Bruxelles (LHUB-ULB), Rue Haute 322, 1000 Brussels, Belgium. Genomic Research Laboratory, Service of Infectious Diseases, Geneva University Hospitals [HUG], 1205 Geneva, Switzerland, Department of Pneumology, CUB-Erasme Hospital, route de Lennik 808, 1070 Brussels, Belgium, Department of Infectious diseases, CUB-Erasme Hospital, route de Lennik 808, 1070 Brussels, Belgium, Intensive Care Unit, CUB-Erasme Hospital, route de Lennik 808, 1070 Brussels, Belgium

Background: Mycoplasma hominis and Ureaplasma sp. are responsible for opportunistic infections in transplant patients, sometimes causing a life-threatening hyperammonemia syndrome. Both pathogens are not identified with standard microbiology techniques, resulting in missed or delayed diagnosis. We present a clinical case that illustrates the added value that Next Generation Sequencing (NGS) may offer in the diagnosis of respiratory infections in immune-compromised patients.

Results: A 55 years-old man with idiopathic pulmonary fibrosis underwent double lung transplantation. He received antibiotic prophylaxis with piperacillin-Tazobactam (TZP) and a classic immunosuppressive regimen. At day 4 post-transplantation (PTx), the patient presented an acute respiratory distress requiring re-intubation. A broncho-alveolar lavage (BAL) was performed, and TZP was switched to Cefuroxime. At day 5 PTx, the patient presented a status epilepticus due to diffuse cerebral oedema. Serum ammonia concentration was 66 1 µmol/dL. BAL bacterial culture was negative. Because of the clinical presentation, special cultures were performed and identified 100.000 CFU/mL of M. hominis and Ureaplasma sp. and specific PCRs were positive for M. hominis and U. parvum. Antibiotic therapy was shifted to azithromycin and doxycycline; within 48h ammonia serum concentrations returned to normal (< 102 µmol/dL). Clinically, the coma persisted several weeks, followed by a persistent frontal lobe syndrome.

A follow-up BAL was performed on day 11 Ptx. The Mycoplasma/Ureaplasma culture was negative, yet the specific PCRs remained positive. Bacterial culture found 100 CFU/ml of Staphylococcus aureus and viral culture was positive for Herpes Simplex Virus. These results were confirmed by whole-metagenome shotgun sequencing (WMGS) as 9.32 x10⁷ genomes were found: 3980/3906 (Forward)/(Reverse) genomes mapped Human alphaherpesvirus-1, and 3804 genomes mapped bacterial phylum of which 37.5% belonged to S. aureus. M. hominis and U. parvum genomes were amplified at 0.98% and 0.15%, in favour of microbiological cure.

Conclusions: WMGS offered added diagnostic and quantitative values compared to classic PCRs which can remain positive after resolved infections. The initiation of appropriate antibiotic therapy would have occurred earlier on, possibly resulting in a better clinical outcome if WMGS had been performed in a routine fashion. The added value of this method should be investigated in a larger cohort of patients.

Quantification and characterisation of antibiotic resistance in greywater discharged to the environment

Seema Porob1, Hillary Craddock2*, Yair Motro2, D Spursi1, Michael Gdalevich4, Nadav Davidovitch3, Zeev Ronen1, Jacob Moran-Gild1

1Ben Gurion University of the Negev, Department of Environmental Hydrology and Microbiology, Zuckerberg Institute for Water Research, Midreshet Ben Gurion, Israel, 2Ben Gurion University of the Negev, MAGICAL Group, Faculty of Health Sciences, Beer Sheva, Israel, 3Soroka University Medical Center, Beer Sheva, Israel, 4Ministry of Health, South District Health Office, Beer Sheva, Israel, 5Ben Gurion University of the Negev, Department of Health Systems Management, Faculty of Health Sciences, Beer Sheva, Israel

Background: In disprivileged communities greywater (wastewater which does not contain effluent from toilets) is often environmentally discharged without treatment. This results in a potential human exposure to associated antibiotic-resistant bacteria (ARB) including extended spectrum beta-lactamase (ESBL)-producers, however this risk is under-studied. We sought to examine the abundance of ARBs (with a focus on ESBLs) and antibiotic-resistance genes (ARGs) in greywater from rural, off-grid Bedouin villages in Southern Israel.

Materials/methods: Greywater samples (n=21) were collected from five Bedouin villages in the Negev (March-November 2018). Serial dilution was carried out to quantify faecal coliforms. ESBL-producers were recovered on CHROMagar ESBL and confirmed by VITEK®2 for ID/AST. Genomic DNA was extracted from the samples and qPCR was used to determine the relative abundances (gene copies/16S rRNA gene) of class 1 integron-integrase intI1 and the following ARGs: blaTEM, blaCTX-M-32, sul1, and qnrS. 16S amplicon sequencing was performed on the Illumina MiSeq and sequences were processed using the QIIME pipeline.

Results: Mean count of isolates recovered by selective plating was 4.6x10⁶ CFUs/100mL (Range:3.0x10⁶-7.4x10⁶ CFUs/100mL). Of 81 presumptive isolates, 15 ESBL-producers were recovered (4 Escherichia coli, 9 Klebsiella spp., 2 Enterobacter cloacae); ESBL-producers were detected in every village. Phenotypically, 86.7% of ESBL-producers were multi-drug resistant. A high abundance of intI1 (0.14 gene copies/16S rRNA), qnrS (0.02 gene copies/16S rRNA), and sul1 (0.05 gene copies/16S rRNA) was observed, followed by blaTEM (3.5x10⁻⁵ gene copies/16S rRNA) and blaCTX-M-32 (2.2x10⁻⁵ gene copies/16S rRNA, Figure 1). Pearson’s correlation analyses showed that total faecal coliform counts were positively correlated to 16S gene copies (p-value=0.001) and total ESBL counts (p-value=0.008). Microbiome analysis showed much diversity between samples, however some commonalities were detected between spatially-related samples. Clustering was observed among some ESBL-producers.

Conclusions: Greywater can be a source of ARBs, including ESBL-producers, in settings characterised by low sanitary conditions and inadequate wastewater management. A multimodal approach combining culture, qPCR, and microbiome studies is especially useful for risk assessment in relation to environmental ARB spread and impact on human health. Such an approach could inform future studies aiming at characterising environmental resistomes in communities worldwide struggling with appropriate sewage management.

Presenter email address: hcraddock5@gmail.com
Tracing of ESBL-producing and ciprofloxacin-resistant Escherichia coli in Belgian broiler and pig farms: a longitudinal study

Sien De Koster, Moniek Ringenier, Christine Lammens, Dieter De Coninck, Marjolein Kluytmans - Van Den Bergh, Jan A. J. W. Kluytmans, Jeroen Dewulf, Herman Goossens

1 University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious Diseases Institute, Antwerp, Belgium, 2 Ghent University, Veterinary Epidemiology Unit, Department of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Merelbeke, Belgium, 3 bioMérieux, Sint-Martens-Latem, Belgium, 4 Amphia Hospital, Department of Infection Control, Breda, Netherlands, 5 Utrecht University, Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands, 6 Amphia Hospital, Microvida Laboratory for Microbiology, Breda, Netherlands

Abstract third-party references: i-4-1-Health Study Group

Background: Resistant Escherichia coli from livestock may be found in food. Retail chicken meat contaminated with ESBL-producing bacteria has been documented in several countries. In addition, ciprofloxacin resistance is found to be high in Belgian livestock. Importantly, the mechanisms of fluoroquinolone resistance in veterinary and human clinical isolates are the same. Whole genome sequencing of resistant bacteria can identify the burden of antibiotic resistance and determine relatedness of resistant bacteria in farms.

Materials/methods: In the i-4-1-Health project, presence of ESBL-producing (ESBL-E. coli) and ciprofloxacin-resistant (CiproR-E. coli) E. coli in fecal samples (FecalSwab, Copan Italy) from Belgian broiler (n=15) and pig (n=15) farms was investigated longitudinally. Per farm, three measurements with a six-month interval were performed between September 2017 and April 2019. When present, three ESBL-E. coli and three CiproR-E. coli from each farm and each measurement were sequenced (Illumina MiSeq). Bioinformatic analysis was performed with BioNumerics (Applied Maths). Core-genome multilocus sequence typing (cgMLST) was used to determine clonal relatedness. A threshold of 20 allelic differences for genetic distances was used to distinguish epidemiologically related/unrelated isolates.

Results: The most common ESBL-gene in ESBL-E. coli from broilers (37%) and pigs (38%) was blaCTX-M-1. Of all CiproR-E. coli, 14% showed plasmid-mediated quinolone resistance (oqxAB, qnrS1, qnrB19), 97% showed mutations at hotspots S83L, D87N in GyrA and/or S80I in ParC and 8% also carried an ESBL-gene. Plasmid-mediated colistin resistance was detected among ESBL-E. coli and CiproR-E. coli in four pig farms (mcr-2.1 n=2, mcr-1.1 n=1, mcr-5.1 n=2, mcr-9.1 n=5) and one broiler farm (mcr-9.1 n=1). The predominant sequence type was ST1158 (7%) in broilers and ST744 (9%) in pigs. Reoccurrence of related ESBL-E. coli and/or CiproR-E. coli within a farm over different measurements was observed in 22/30 farms, indicating recirculation of isolates within farms [Figure-1]. Clonally related E. coli were detected among different broiler farms, but not among pig farms.

Conclusions: Recirculation of clonally related E. coli suggests that resistant strains reside in the farm environment. The occurrence of related strains among different broiler farms suggests a common reservoir (e.g. at top of the pyramid in the broiler production system) or transmission of resistant bacteria.
Figure 1: Minimum spanning trees based on cgMLST of ESBL-E. coli and CiproR-E. coli from broilers (A and B) and pigs (C and D) in Belgium. Colours represent different farms (F) and measurements (M). Branch numbers represent allelic differences. Clonally related isolates are partitioned when allelic differences are ≤ 20.

Optimal detection of multidrug-resistant Gram-negatives from stools
Claudine Fournier¹, Mustafa Sadek¹, Laurent Poirel¹, Patrice Nordmann*¹

¹University of Fribourg, Fribourg, Switzerland

Background: Early detection of multidrug-resistant (MDR) bacteria in colonized patients is becoming crucial to prevent infections. In many health care settings, screening of hospitalized patients is performed as routine for infection control measures. However, the optimal detection strategies are not well established. This study evaluated different screening strategies: non-enrichment, non-selective enrichment, and selective enrichment steps prior to inoculation on selective agar plates for the detection of seven types of clinically-relevant MDR bacteria, namely extended-spectrum β-lactamase-producing Enterobacterales (ESBL-E), carbapenemase-producing Enterobacterales (CPE), polymyxin-resistant Enterobacterales (PMR-E), carbapenemase-producing Acinetobacter baumannii (CRAB), polymyxin-resistant A. baumannii (PMR-AB), carbapenem-resistant Pseudomonas aeruginosa (CRPA), and polymyxin-resistant P. aeruginosa (PMR-PA) from spiked stools.

Materials/methods: A collection of MDR Gram negative bacteria was used to test enrichment strategies. Two procedures were compared, namely an enrichment step in tryptic soy broth (TSB) and an enrichment step using TSB supplemented with antibiotic. Different antibiotic concentrations were chosen below EUCAST and CLSI breakpoint values. Commercially-available selective agar plates were used including ChromID-ESBL, SuperPolymyxin, SuperCarba, CHROMagar-Pseudomonas supplemented with meropenem (2 mg/L), and CHROMagar-MDR-Acinetobacter agar plates. Stool suspension spiked with given MDR bacteria were inoculated in three different procedures: a) directly on the selective media, b) into 5 mL of non-selective TSB, or c) into 5 mL of TSB supplemented with antibiotic. Colony-forming units (CFU) were counted after 18h of incubation at 37°C.

Results: The impact of the three different procedures revealed significant differences. Following TSB enrichment, the detection of MDR bacteria was significantly improved when compared to direct plating on selective medium (100,000-fold). Furthermore, the use of selective enrichment containing antibiotic, respectively supplemented with cefotaxime (0.1 mg/L), ertapenem (0.1 mg/L), colistin (0.5 mg/L), and meropenem (0.1 mg/L), improved the detection of MDR bacteria compared to non-selective enrichment step (10,000 fold).

Conclusions: The use of selective enrichment broths prior to direct inoculation onto selective culture media resulted in significant increased growth of all MDR bacteria tested. This screening protocol might be the best option to improve the sensitivity of the screening process, being a relatively low-cost, easy-to-implement strategy when performing extended surveys either in human, animal or environmental settings.

Antimicrobial stewardship and infection control programmes on the incidence of carbapenem-resistant Klebsiella pneumoniae: a nonlinear time-series analysis

Marianna Meschiari1*, César Nebot2, Arielle Beyaert3, Mario Sarti4, Andrea Bedini1, Gabriella Orlando1, Jose Maria Lopez Lozano5, Cristina Mussini2

1Infectious Disease Clinic, Azienda Ospedaliero-Universitaria di Modena; University of Modena, Modena, Italy, 2Economics. Centro Universitario de la Defensa-UPCT, San Javier, San Javier, Spain, 3Econometrics. Universidad de Murcia, Murcia, Spain, 4Clinical Microbiology Laboratory, University Hospital of Modena, Modena, Italy, 5Research Group on Health Sciences Data Analysis. University of Murcia, Murcia, Spain

Abstract third-party references: Supported by THRESHOLDS study group

Background: There is lacking evidence for effective strategies to contain the spread of carbapenem-resistant Klebsiella pneumoniae [KLEBCRE] in highly endemic hospitals. Our aim was to quantify the effectiveness of sequential infection control and antimicrobial stewardship (ABS) programs to reduce the spread of KLEBCRE.

Materials/methods: A non-linear time-series analysis (NL-TSA) exploring temporal associations between consecutive infection control interventions [hand hygiene (iHAND Campaign) and ABS (iASP Campaign)] and Incidence Density of KLEBCRE (DI_KLEBCRE) in Azienda Ospedaliero-Universitaria Policlinico Modena was conducted. We used the statistical approach elsewhere described (López-Lozano JM, et al. Nat Microbiol. 1160–1172, 2019) in order to adjust a non-linear model (Multivariate Adaptive Regression Splines) with endogenous identification of thresholds. Moreover, we evaluate the effectiveness of different interventions with a counterfactual analysis.

Results: Previous DI_KLEBCRE, alcoholic gel consumption (ALCBED) and recent hospital antimicrobial use [carbapenems and cephalosporins] were explanatory variables in the best-fit [adjusted-R²=0.539] NL-TSA model. We identified a threshold at 12.43 liters per 1000 occupied bed days [OBDs] for alcoholic gel consumption (ALCBED) above it, each additional liter per 1000 OBDs decreased the DI_KLEBCRE by 0.005 new cases per 1000 OBDs. Regarding antimicrobial consumption, we identified two thresholds: 46 DDD/1000 OBDs for Carbapenems (CARBA) and 98 DDD/1000 OBDs for Cephalosporins (CEFARES); above these thresholds, the KLEBCRE increased by 0.035 and 0.089 new cases per 1000 OBDs, respectively (figure 1). With a counterfactual analysis, we estimate that iCARBA and iASP reduced KLEBCRE by a monthly average of 0.035 (0.008, 0.058; CI-95%) per 1000 bed-days, the total accumulated decrease being of 2.5. Combining these campaigns with iHAND we estimate a decrease of KLEBCRE by 0.06 (0.028,0.092; CI-95%), with a total accumulated decrease of 4.57.

Conclusions: Antimicrobial stewardship, hand hygiene and target screening are essential components to reduce the spread of KLEBCRE in endemic settings. Our results confirm the hand hygiene central role to reduce KLEBCRE nosocomial transmission. The DI KLEBCRE increased significantly when the hospital uses of carbapenems and cephalosporins exceeded minimum thresholds. This finding could provide quantitative targets to drive ABS strategy.
Abstract 4326

The solitary parE-type toxin gene in *Pseudomonas aeruginosa* sequence type 111 clinical isolates collected in a paediatric intensive care unit in Moscow

Yulia Bocharova*1, Tatiana Savinova1, Dmitry Shagin1, Igor Chebotar3

1National Medical Research Center for Children’s Health, Moscow, Russian Federation, 2Central Research Institute of Epidemiology, Moscow, Russian Federation, 3Pirogov Russian National Research Medical University, Moscow, Russian Federation

**Background:** Bacteria can survive antibiotic treatment using several strategies, including adaptive resistance, tolerance and persistence. The investigation of bacterial survival strategies is an important challenge in clinical microbiology.

**Materials/methods:** This study included ten *Pseudomonas aeruginosa* sequence type 111 strains isolated from a pediatric intensive care unit in Moscow (2012-17). Minimal inhibitory concentration (MIC) values were determined using Sensititre Gram Negative MIC Plates (Thermo Fisher Scientific); the results were interpreted according to the EUCAST criteria. Whole genome sequencing (WGS) was performed on the Illumina Hiseq 2500 platform. BLAST, ResFinder service and ISsaga tool were used for analysis of WGS data.

**Results:** All *P. aeruginosa* isolates were colistin-only susceptible and demonstrated resistance to piperacillin-tazobactam, ticarcillin-clavulanic acid, ceftazidime, meropenem, imipenem, amikacin, netilmicin, ciprofloxacin. A number of resistance genes, including *bla*VIM-2*, aacA29a*, *aph(3')-IIb*, *crpP*, *fosA* and *sul1*, were found in all strains. In two isolates, an insertion sequence (IS) element containing the transposase gene and inverted repeats identical to those of ISPa40 was detected. The IS element was located within the polyketide cyclase gene (*pc* gene) at nucleotide position 59. In contrast to reference ISPa40, IS detected in the present study contained a passenger gene homologous to *parE* (*parE-type* gene) encoding RelE/ParE super-family toxin, which is known to be a part of toxin-antitoxin system and induce persister formation. The *parE-type* gene was 447 bp in length and resembled *parE* from *Pseudomonas graminis* (58% query cover, 98% identity). The genetic environment of the detected *parE-type* gene is presented in Figure 1. No corresponding antitoxin genes were found in *parE-type*-positive *P. aeruginosa* isolates, therefore *parE-type* was a solitary toxin gene.

**Conclusions:** We hypothesize the detected *parE-type* gene can spread among bacterial isolates via IS element and confer to bacteria an ability to form persister cells under antibiotic treatments.

Global outbreak of *Mycobacterium chimaera* infections in cardiac surgery patients: tracking risk through ongoing surveillance in the UK

Theresa Lamagni*, Andre Charlett¹, Brendan Mason⁵, Jenny Wares⁵, Eleri Davies⁵, Jim Mcmenamin¹, Lorraine Doherty¹, Grace Smith¹, Meera Chand¹

¹Public Health England, London, United Kingdom, ²Public Health Wales NHS Trust, Cardiff, United Kingdom, ³NHS Highland, Inverness, United Kingdom, ⁴Health Protection Scotland, Glasgow, United Kingdom, ⁵Public Health Agency Northern Ireland, Belfast, United Kingdom

**Background:** Global distribution of *Mycobacterium chimaera* contaminated heater cooler units used in open-heart surgery has resulted in one of the most widespread multicenter hospital outbreaks described to date, with cases documented in 13 countries spanning 4 continents. Prospective monitoring established in 2015 by Public Health England in collaboration with Devolved Administrations informed UK risk mitigation strategies. We assess changes in risk since implementation of these measures, including enhanced device decontamination, advice on theatre positioning and patient notification of early signs and symptoms.

**Methods:** Following initial retrospective case finding, laboratories were requested to report prospective cases meeting our case definition - *Mycobacterium chimaera* endocarditis, surgical site infection or disseminated infection within 10 years of cardiopulmonary bypass (cardiothoracic surgery, extracorporeal membrane oxygenation or other procedure involving heater cooler units). Risk to patients in England was quantified using denominators derived from NHS Digital Hospital Episode Statistics.

**Results:** 45 *Mycobacterium chimaera* outbreak cases have been identified to date in the UK. Patients had undergone surgery in 22 cardiac centres, including 2 private facilities. Most [39] had heart valve surgery, the remainder coronary artery bypass or aortic graft surgery. The earliest case underwent surgery in 2007 and the most recent in 2016. Median interval between surgery and microbiological diagnosis was 23 months (<1 month to 68 months) with a decrease from 27 to 12 months from 2007-11 to 2016. Analysis of data from England indicated a crude risk of 0.19 per 1000 patients undergoing heart valve surgery from 2007 to 2018 (1 in 5000). Assuming a 5y period of risk, incidence peaked in 2014 at 1.48 cases per 10,000 person-years of follow-up, with significant decrease from 2014 to 2018 (RR=0.51, 95% CI 0.31-0.84). To date, just over half (25) of cases have died, with deaths within 1y of diagnosis (n=16) dropping between 2007-11 and 2016.

**Conclusions:** Whilst cases linked to this global outbreak continue to be diagnosed in the UK, risk estimates suggest a substantial reduction since the implementation of control measures in 2015. With limited effectiveness of treatment, outcomes for patients remain very poor, highlighting the devastating impact of this unique outbreak.

ABSTRACT BOOK – 30th ECCMID 2020

Abstract 4333

**Chronic mucocutaneous candidiasis in children in Saint Petersburg, Russia**

Olga Kozlova1, Ekaterina Frolova1, Tatjana Bogomolova1, Evgeny Suspsitsin2, Tatjana Gabrusskaja3, Elizaveta Dosovitskay3, Nikolai Klimko*1

1North-Western State Medical University named after I.I. Mechnikov, Ministry of Public Health of Russian Federation, Saint-Petersburg, Russian Federation, 2St. Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation, 3Children’s City Multidisciplinary Clinical Center for High Medical Technologies, St. Petersburg, Russia, Saint-Petersburg, Russian Federation

**Background:** Chronic mucocutaneous candidiasis (CMC) is a rare hereditary disorder characterized by persistent and recurrent infections by Candida due to changes in cellular immunity and may be associated with autoimmune endocrine disorders.

**Materials/methods:** Molecular genetic studies were performed with multigenic targeted sequencing (MiSeq, Illumina, USA).

**Results:** In prospective single center study included 11 patients with CMC. Median age was – 7.5 y, range - 6 to 13 y, males - 92%. Molecular genetic study has shown heterozygous mutation in the STAT1 gene in 4 patients and mutations in autoimmune regulator (AIRE) in 7 patients. Sites of candidiasis were oral mucosa – 100%, skin – 54%, esophagus – 46%, and nails – 31%. *Candida albicans* was isolated in all patients. Recurring CMC was diagnosed more than 4 times per year in all patients. Endocrine disorders were present in patients with AIRE syndrome: primary adrenal insufficiency – 71%, hypoparathyroidism – 71%, autoimmune thyroiditis with hypothyroidism – 29%; autoimmune disorders: autoimmune gastritis – 71%, alopecia – 29%, hematological disorders: lymphopenia – 30%, pernicious anemia – 14%. In patients with impaired STAT1 were lymphopenia – 50%, autoimmune gastritis 25%, other skin infections (*Streptococcus spp.*, *Malassezia spp.* ) – 25%. On susceptibility testing one *Candida albicans* (18%) was resistant to fluconazole and voriconazole. Patients with exacerbations of CMC receive fluconazole 3 mg/kg/day for two weeks, then 3 mg/kg/day once per week for 2 months with clinical response and disappearance of symptoms in 9 patients. Patient with azole resistant *Candida albicans* received itraconazole with clinical effect.

**Conclusions:** In 100% patients with mutations in AIRE and STAT1 genes diagnosed candidiasis of oral mucosa, 54% - candidiasis of skin. Endocrine system disorders, autoimmune diseases, hematological disorders was diagnosed in patients CMC with mutations in autoimmune regulator AIRE. Lymphopenia, autoimmune gastritis, other skin infections was diagnosed in patients CMC with mutations in STAT1.

Abstract 4335

Risk factors associated with carbapenemase-producing Enterobacteriaceae infection

Laura Corbella Vazquez*,1, Mario Fernandez Ruiz2, Maria Ruiz-Ruigómez1, Jose Tiago Sequeira1, Isabel Rodriguez Goncer1, Maria Pilar Hernandez Jimenez1, Francisco Lopez-Medrano1, Jennifer Villa1, Jose M. Aguado Garcia1, Rafael San Juan Garrido1

1Unit of Infectious Diseases. University Hospital 12 de Octubre, Instituto de Investigación Hospital “12 de Octubre” [imas12], Madrid, Spain, 2Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” [imas12], Unit of Infectious Diseases, Madrid, Spain, 1Unit of Microbiology. University Hospital 12 de Octubre, Instituto de Investigación Hospital “12 de Octubre” [imas12], Madrid, Spain

Background: In most of published studies looking for risk factors for carbapenemase-producing Enterobacteriaceae (CRE) infection, matching was exclusively based on the presence of bacteremia, regardless of the source of infection or admission department.

Materials/methods: We performed a case-control study to evaluate risk factors for CRE infection including all first episodes between 06/2013 and 12/2016. We selected episodes of infection due to non-CRE Enterobacteriaceae as controls [non-CRE], matched [1:1 ratio] by clinical syndrome, previous invasive procedure and admission department.

Results: We included 136 CRE and 136 non-CRE episodes. Baseline characteristics were similar except for cardiovascular disease, that was more frequent in cases [52.2% vs. 41.2%; odds ratio [OR]: 1.882; 95% confidence interval [95%CI]: 1.045-3.390; p=0.035]. Hospital admission in the previous 90 days was more common in cases [51.5% vs. 28.7%; OR 3.214; 95%CI: 1.764-5.856; p <0.0001], with more cumulative days of hospital stay [median: 29.0 vs. 16.0; OR: 1.047; 95%CI: 1.026-1.069; p <0.0001]. Previous infection by a multidrug resistant microorganism [16.2% vs. 2.9%; OR: 5.500; 95%CI: 1.895-15.960; p=0.002] and CRE colonization [62.5% vs. 2.2%; OR 65.289; 95%CI: 8.749-487.332; p <0.0001] were more frequent in cases. The following treatment-related variables were also more common in this group: antibiotic therapy in the previous 90 days (81.6% vs. 44.9%; OR: 13.500, 95%CI: 4.889-37.725; p <0.0001), cumulative days of therapy [median: 20.0 vs. 15.0; OR: 1.030, 95%CI: 1.005-1.057; p=0.0219], and previous use of carbapenems [40.4% vs. 14%; OR: 4.600, 95%CI: 2.321-9.115; p <0.0001], quinolones [31.6% vs. 8.8%; OR: 5.429, 95%CI: 2.424-12.156; p <0.0001] and cephalosporins [31.6% vs. 18.4%; OR: 2.125, 95%CI: 1.173-3.850; p=0.016]. After adjusting by conditional logistic regression, previous renal replacement therapy [adjusted OR [aOR]: 4.924, 95%CI: 1.283-18.898; p=0.020], cumulative hospital stay within the previous 90 days [aOR [per one-day increment]: 1.034, 95%CI: 1.010-1.059; p=0.005], and previous use of quinolones [aOR: 9.516; 95%CI: 2.997-30.213; p <0.0001] and carbapenems [aOR: 3.339; 95%CI: 1.332-8.373; p=0.010] remained as independent risk factors.

Conclusions: After matching by source of infection and admission department, previous renal replacement therapy, cumulative hospital stay within the previous 90 days and previous treatment with quinolones and carbapenems emerged as risk factors for CRE-infection.

Host biomarkers to differentiate bacteraemias from microbiologically proven viral infection in adults with acute fever episodes attending outpatient clinics in Tanzania

Loic Lhopitallier, Melissa Richard-Greenblatt, Kathleen Zong, Zainab Mbarak, Josephine Samaka, Tarsis Mlaganile, Theckla Kazimoto, Aline Mamin, Blaise Genton, Laurent Kaiser, Kevin Kain, Valérie D’acremont, Noémie Boillat-Blanco

1Service des Maladies Infectieuses, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, 2Toronto General Hospital, Toronto, Canada, 3Mwananyamala Hospital, Dar es Salaam, Tanzania, 4Ifakara Health Institute, Dar es Salaam, Tanzania, 5University Hospital Geneva, Geneva, Switzerland, 6Swiss Tropical and Public Health Institute, Basel, Switzerland, 7Department of Sciences, University of Basel, Basel, Switzerland, 8Department of Vaccination et Médecine des Voyages, Département des Policliniques, Université Lausanne, Switzerland, 9Laboratoire de Virologie, Hôpitaux Universitaires de Genève, Genève, Switzerland, 10Département de Formation, Recherche et Innovation, Université Lausanne, Switzerland

Background: Patients with bacterial and viral infections have overlapping clinical presentations. Amongst febrile patients, discriminating between both groups is paramount for correct and timely therapeutic decision-making. There have been mixed results in the study of host biomarkers to this effect. We aimed to test the predictive validity of biomarkers in a microbiologically well-characterized cohort to overcome potential overlaps.

Materials/methods: Consecutive adults with temperature >38°C were recruited and the study team collected a detailed medical history and clinical examination. Blood and nasopharyngeal samples were taken to perform rapid tests, serologies, cultures and molecular analyses for infectious pathogens.

We then identified a group of patients with microbiologically-proven infections: 1) bacterial infection defined as positive blood cultures and 2) viral infection defined as patients with fever without focus and positive dengue RDT, acute HIV infection (positive p24 antigen only), acute EBV/CMV infections (IgM positive, IgG negative) and chickenpox (positive VZV PCR on skin swab).

Plasma concentrations of markers of endothelial (Angpt-2, sFlt-1, sVCAM-1, sICAM-1) and immune (sTREM-1, IL-6, IL-8, CHI3L1, sTNFR1, PCT, CRP) activation pathways were quantified using Luminex and ELISA. We evaluated the accuracy of these mediators in discriminating bacterial from viral infections.

Results: Of 507 patients we selected 172 patients with microbiologically-proven infections. 23 with bacterial infections [12 Salmonella typhi and S. paratyphi, 4 Streptococcus pneumoniae and 7 others]. 149 with viral infections of which 134 dengue, 4 acute HIV infections and 12 herpesvirus. Chronic HIV was significantly more prevalent in the bacterial infection group (48% versus 9%; p<0.01).

The top 3 predicting biomarkers were chitinase-3-like protein-1, procalcitonin and soluble-tumour-necrosis-factor-receptor-1 (area under the receiver operating characteristic [AUROC] 0.82 [95% CI 0.81-0.94], 0.86 [0.78-0.94] and 0.85 [0.73-0.96]). Adding PCT to HIV screening significantly improved the diagnostic performance [AUROC 0.69 [0.59-0.80] versus 0.90 [0.83-0.97]; p<0.01]

Conclusions: Systematic HIV screening of febrile patients identifies patients at higher risk of bacteremia. By combining it with a commercially available biomarker point-of-care test, procalcitonin, our results showed an excellent discriminatory power between bacterial and viral infections. An algorithm based on both tests for patient management has the potential to improve outcomes and decrease inappropriate antibiotic prescriptions.

Vanvitelli, Italy, 15Infectious Diseases and Viral Hepatitis, Department of Mental and Physical Health and Preventive Naples, Italy

Background: direct-acting antivirals (DAA)-regimens are associated with failure in about 5%. The failure was associated with the emergence of resistance associated substitutions [RASs]. This real-life study characterized the virological patterns in patient failing to DAA and evaluated the efficacy of retreatment.

Materials/methods: all the consecutive 207 HCV patients failed to DAA observed at the laboratory of infectious diseases of University of Campania, Naples were enrolled. All the patients were treated according to HCV genotype, international guidelines and local availability. Sanger sequencing of NS3, NS5A and NS5B was performed at failure by home-made protocols.

Results: Patients enrolled were mainly males (68.1%) with median age 65[31-89]. 86% were Relapse, 8,7%no Responder,5,3% Breakthrough, 35 (17% %) were re-treated. Table 2 shows the epidemiological, clinical and virological characteristics of the 35 retreated patients. At failure, 68,5% of patients presented one RAS and 42,8 % had 2 or more RAS. 17 (48,6%) obtained SVR. The 7 re-treated patients with genotype 3 most frequently (41,2%) showed SVR than the patients with genotype 1 (29,4%), 2 (23,6%) and 4 (5,8) but without statistical significance.

We analyze the SVR prevalence according to previous/latest DAA regimen, RASs distribution and Resistance-Guided Therapy [RGT]. Patients retreated with the latest DAAs regimen most frequently obtained SVR than patients retreated with previous generation of DAA (76.6% vs 13.3%, p<0.05). Patients with SVR most frequently had RGT (63.4% vs 26.6%, p<0.05).

Conclusions: The prevalence of RASs was high in our real-life population. Failed patients have at least one RASS in one HCV region. The latest DAA regimen more frequently obtained SVR despite previous regimen. Patients with RGT more frequently obtain SVR. NS3, NS5A and NS5B sequencing seems mandatory in the choice of re-treatment DAAs.

Abstract 4341

Extrapulmonary tuberculosis among migrants in Europe
Sally Hayward*1,2, Teymur Noori3, Laura B. Nellums1,4, Sally Hargreaves1, Jon S. Friedland1

1St George’s, University of London, London, United Kingdom, 2London School of Hygiene & Tropical Medicine, London, United Kingdom, 3ECDC, Solna, Sweden, 4University of Nottingham, Nottingham, United Kingdom

Background: The proportion of tuberculosis (TB) cases in Europe that occur in migrants is increasing. While not transmissible, extrapulmonary TB (affecting organs other than the lungs) poses challenges in diagnosis and treatment and causes serious morbidity and mortality. To date, there has been no in-depth exploration of extrapulmonary TB in migrants across Europe.

Materials/methods: We analysed 22 years of data from the European Centre for Disease Prevention and Control’s European Surveillance System (TESSy) for 31 EU/EEA countries collected between 1995 and 2017. We investigated whether the proportion of TB cases that were extrapulmonary varied between migrants and non-migrants, and whether this varied by a) country/region of origin, b) reporting country/region, and c) site of disease. All analyses were conducted in StataSE v15.

Results: 1,270,896 TB cases were included in the analysis, comprising 326,987 (25.7%) migrants, and 943,909 (74.3%) non-migrants. 45.2% (n=147,814) of cases among migrants were extrapulmonary, compared to 21.7% (n=204,613) among non-migrants (χ²=6.7x10⁴, p<0.001). The mean age of all included migrants with TB was 38 years, and 59.9% were male, compared with 48 years and 40.1% male in non-migrants. Among extrapulmonary TB cases, specific site varies by migrant status (χ²=1.9x10⁴, p<0.001). For migrants, 47.6% of extrapulmonary TB is lymphatic, compared with 25.3% in non-migrants. Bone/joint and peritoneal/digestive TB are also relatively more common in migrants than in non-migrants. The majority of migrant extrapulmonary TB cases were from South-East Asia (n=55,390) and Sub-Saharan Africa (n=38,319), with the highest proportions of extrapulmonary TB seen among migrants from these regions (62.0% and 54.5% respectively). A relatively low proportion of extrapulmonary TB was seen in Eastern Europe (17.4%) compared with Northern/Western Europe (38.7%), where the proportion of extrapulmonary TB is greater in foreign-origin cases (49.7% extrapulmonary in foreign-origin vs. 27.2% in native-origin, χ²=2.6x10⁴, p<0.001).

Conclusions: Among TB cases in the EU/EEA, the proportion of cases that are extrapulmonary is higher in migrants than in non-migrants, particularly among those from South-East Asia and Sub-Saharan Africa. This pattern is seen primarily in final destination countries in Northern and Western Europe, which has clinical and policy implications for patient management.

Significant increase in the prevalence of macrolide resistance-mediating mutations in Mycoplasma genitalium from 2014 to 2019

Guzel Khayrullina*1, Tamara Makhova1, Elena Goloveshkina1, Guschin Alexander2

1 Federal Budget Institute of Science "Central Research Institute for Epidemiology", Moscow, Russian Federation, 2 Moscow Scientific and Practical Center of Dermatovenereology and Cosmetology DZM, Moscow, Russian Federation

Background: Mycoplasma genitalium is the second cause of non-gonococcal urethritis and non-gonococcal cervicitis after C.trachomatis. The recommended first-line treatment for uncomplicated M. genitalium infection according 2016 European guideline is Azithromycin 500 mg on day one, then 250 mg od days 2–5. But the last 10 years was shown the essential decrease of azithromycin efficacy and now it is approaching 60%. The azithromycin treatment failure is caused by appearance of macrolide resistance-mediating mutations in region V of the 23S rRNA gene M.genitalium.

Materials/methods: The study objective was to compare the prevalence of macrolide resistance associated mutations in M. genitalium positive patients in 2014-2015 and in 2018-2019. Samples from 400 M. genitalium positive patients who attended non-STD clinics in Moscow were collected in 2014-2015 and 125 in 2018-2019. Among received 525 urogenital samples 353 (67%) were from females and 172 (33%) from males. The extracted DNA from the samples were amplified with primers specific for V region of 23S rRNA gene M. genitalium. Antibiotic resistance-associated mutations were identified using conventional Sanger sequencing.

Results: The prevalence of macrolide resistance associated mutations was shown about three times higher in 2018-2019 than in 2014-2015: 13.6% and 4.75%, respectively. There was no significant difference in the mutation’s prevalence between men and women. The most prevalent macrolide resistance-mediating mutation - A2059G was the same in 2014-2015 and in 2018-2019 and it’s prevalence was 68.4% and 58.8%, respectively. The second most prevalent mutation was A2058G: 26.3% in 2014-2015 and 23.5% in 2018-2019. And the rarest mutations were A2062G – 5.3% in 2014-2015 and A2058T - 17.6% in 2018-2019.

Conclusions: Study showed the macrolide resistance-mediating mutations prevalence growth by about three times over 4 years, this can lead to significant problems with M. genitalium infection treatment after 3-4 years. Our data highlights the need for optimization treatment protocol and development diagnostics assays for detection antibiotic-associated mutations in M. genitalium in Russia.

Abstract 4347

Risk factors for Chlamydia and gonorrhoea infections and STI testing uptake amongst youth in Harare, Zimbabwe

Kevin Martin*1,2, Michael Marks2, Nyasha Buwu1, Ethel Dauya1, Joyce Muzangwa1, Ioana-Diana Olaru1,2,3, Katharina Kranzer2,3, Rashida Ferrand2,3

1Brighton & Sussex Medical School, Brighton, United Kingdom, 2London School of Hygiene & Tropical Medicine, London, United Kingdom, 3Biomedical Research and Training Institute, Harare, Zimbabwe

Background: Sexually transmitted infections (STIs) contribute to significant morbidity globally, and youth are particularly vulnerable. In low resource settings, syndromic management is recommended. There is therefore limited evidence regarding factors associated with uptake of STI testing in these settings, as well as sparse data on STI prevalence and risk factors for STIs.

Materials/methods: A cross-sectional mixed methods observational study was nested within a cluster randomised trial assessing the impact of a community-based package of sexual health services for youth aged between 16 and 24 years inclusive, in Harare, Zimbabwe. Testing for chlamydia and gonorrhoea was offered as part of this package of services. Questionnaires were used to collect data on sociodemographic characteristics, sexual and reproductive history, knowledge of STIs, attitudes towards STI testing and attitudes and perceived barriers to partner notification. Testing for gonorrhoea and chlamydia infection was performed on urine samples using the Cepheid GeneXpert platform. Univarate analysis and multivariate logistic regression was used to assess factors predicting STI testing uptake and a positive STI result.

Results: Of 350 participants accepting testing, prevalence of chlamydia and gonorrhoea infection was 16.3% and 3.7%, respectively. Number of different sexual partners in the preceding year was the only factor significantly associated with having an STI on univariate analysis. Multivariate analysis revealed a strong association between female gender and a positive STI result.

Among the 243 participants included in the testing uptake analysis, older age, female gender, being employed, being married compared to single, having no recent new sexual partners and not using a condom at the most recent sexual encounter were all significantly associated with accepting STI testing in univariate analyses. The presence of current symptoms was significantly associated with accepting testing in both univariate and multivariate analyses.

Conclusions: The high prevalence of chlamydia and gonorrhoea amongst youth in Harare demonstrate the limitations of syndromic management. Regarding testing, presence of symptoms appeared to be a driving factor for uptake. Furthermore, younger males had particularly poor uptake and so should be encouraged to test. However, this should not be at the expense of females who had higher odds of having an STI.

**Outcomes of bacteraemic and non-bacteraemic patients presenting to the emergency department**

Rebecca Sparks*, Ruchir Chavada1, Christopher Trethewy1, Arisa Harada1

1Gosford Hospital, Gosford, Australia

**Abstract third-party references:** Emergency Department, Gosford Hospital, Department of Medicine, Gosford Hospital, Department of Microbiology and Infectious Diseases, NSW Health Pathology-Central Coast

**Background:** Bacteraemia is a major cause of sepsis and is associated with high morbidity and mortality. Delayed antibiotic treatment in the septic shock population has previously been associated with poorer outcomes. We designed this study to look at the outcomes between bacteraemic and non bacteraemic patients.

**Materials/methods:** This was a retrospective cohort study performed in two metropolitan hospitals in NSW. The first cohort included adult patients (>18 years) with positive blood cultures (bacteraemia with a true pathogen). The second cohort consisted of patients matched by age to the first without bacteraemia. Data was collected on demographics and outcomes including length of stay, ICU admission and ICU length of stay, in-hospital mortality related to sepsis and antibiotic duration. Mortality associated with time to antibiotics was evaluated in both cohorts.

**Results:** There were 251 patients in each cohort. Sepsis-related mortality was higher in the bacteraemic group (OR 0.4, p=0.03). Bacteraemic patients had longer hospital admissions (10.7 vs 7.5 days, p<0.001) and longer antibiotic duration (15.44 versus 8.20 days, p=0.001). There was no difference in ICU admission (p=0.55) or ICU length of stay (p=0.11). Antibiotics administered within an hour of triage did not improve overall mortality in the bacteraemic group (p= 0.64).

**Conclusions:** Bacteraemic patients have higher sepsis-related mortality, longer length of hospital admission and longer antibiotic duration when compared with non bacteraemic septic patients. Antibiotics administered within one hour of triage did not improve sepsis mortality related outcomes.

Abstract 4351

**Evaluation of a multiplex PCR in genital ulceration diagnosis**

Laura Verdurme*1, Arnaud Lheude1, Eric Hedbaut1, Sabine Trombert Paolantoni1, Nesrine Day1, Stephanie Haim-Boukobza1

1Laboratoire Cerba, Saint Ouen l’Aumone, France

**Background:** Genital ulcerations can be hard to diagnose because different pathogens can be involved and lesions can be atypical. The aim of this study was to evaluate the analytical performances and the clinical impact of using a multiplex PCR (Allplex genital ulceration Seegene) in genital ulceration diagnosis at laboratory.

**Materials/methods:** First, analytical performances on 38 known samples were compared, using sample positive for HSV1, HSV2 and VZV (simplex PCR Sacace), *Haemophilus ducreyi* (Vircell standard), *Chlamydia trachomatis* serovar L (genotyped by the French National Reference Center) and *Treponema pallidum* (patient presenting with positive VDRL serology, with an available swab and/or positive direct examination by immunofluorescence). Then, we studied patient samples (=38) received in Cerba laboratory from February to July 2019 with a request of only *Treponema pallidum* or *Haemophilus ducreyi* PCR, or genital ulceration multiplex PCR. We notified also those for which the evidenced pathogen was not initially prescribed.

**Results:** 38 samples have then been compared to simplex tests for analytical performance evaluation. The different samples studied were anal (n=11), genital (n=8), 4 peripherical from a newborn; urine (n=1); urethral (n=1), external quality controls (n=12), and commercial standard (n=1). Results showed 100% concordance, the discrimination between HSV1 and HSV2 and between L and no-L *Chlamydia trachomatis* was perfect. (table 1) Then, among the 38 patient samples: 16 were positive for at least one target and 22 were negative. We found 11 HSV; 3 *Treponema pallidum*; 1 VZV and 1 *Chlamydia trachomatis* serovar L. (table 2) From the 16 positive samples, multiplex PCR testing allowed to diagnose 7 pathogens which were not initially prescribed.

**Conclusions:** Analytical performances of the genital ulceration multiplex PCR (Allplex Seegene) were satisfactory, with sensitive and specific detection, and can be used as an epidemiological tool. Moreover, it allowed detection of non-prescribed pathogens.

**Presenter email address:** laura.verdurme@lab-cerba.com
Abstract 4352

**Clonal spread of multidrug-resistant penicillin-nonsusceptible *Streptococcus agalactiae***

Jeonghyun Chang*1, Heungsup Sung2, Mi-Na Kim2

1Ilsan Paik Hospital, Department of Laboratory Medicine, Goyang, South Korea, 2University of Ulsan College of Medicine and Asan Medical Center, Department of Laboratory Medicine, Seoul, South Korea

**Background:** Penicillin is the first-line antibiotics for treatment and *S. agalactiae* is generally susceptible to penicillin. Three cases of penicillin non-susceptible *S. agalactiae* (PNSA) were isolated from respiratory specimens. Those three strains were analyzed for genomics and phenotypic characteristics.

**Materials/methods:** Antimicrobial susceptibility of 3 PNSA was analyzed using Microscan® STREP MSP6+ panel (Dade Bahning, West Sacramento, CA, USA) and penicillin minimal inhibitory concentration (MIC) was determined by Etest (BioMerieux, St Laurent, QC, France). Whole genome of 3 PNSA were obtained using PacBio 20-kb platform (Pacific Biosciences, USA), which were compared to whole genome of 16 reference strains. RNA transcriptomics of those strains were quantified compared to *Streptococcus agalactiae* ATCC13813 as the reference. Antimicrobial resistance and virulence factor genes were searched from whole genome data. Molecular epidemiology was investigated by multi-locus sequence typing (MLST), serotyping by sequencing, single nucleotide polymorphism (SNP) of penicillin-binding protein (PBP) gene and similarity of whole genomes.

**Results:** Three PNSA were susceptible to ampicillin, chloramphenicol, cefotaxime, daptomycin, linezolid, meropenem and vancomycin, and resistant to clindamycin, erythromycin, levofloxacin, and tetracycline. MICs of penicillin were 0.19 µg/ml, 0.5 µg/ml, and 0.25 µg/ml in SA1, SA2, and SA3, respectively. Three strains were all ST10. Each of three PNSA strains generated the whole genomes of 2,445,137 bp, 2,528,754 bp, and 2,486,170 bp, respectively and carried variable numbers of SNP to 16 reference genomes from minimum of 5,282 to maximum of 19,229. There were 170 SNP detected common in all PNSA and belonged to 96 coding sequences. The three isolates were differed by 214 to 603 SNPs each other and genomic similarity between 3 PNSA were more than 99.96%. All 3 isolates possessed same mutations of G398A, V405A, Q557E amino acid substitutions in pbp2x gene. There was no difference of RNA expression within genes of penicillin-binding proteins.

**Conclusions:** PNSA have been clonally spread in community. Causes of penicillin non-susceptibility of *S. agalactiae* were PBP aberration induced by deleterious amino acid substitutions and not by quantitative changes of PBP protein. Penicillin resistance should be monitored among *S. agalactiae* in Korea.

Abstract 4362

Population pharmacokinetics of ceftriaxone administered as continuous or intermittent infusion in critically ill patients
Emiel Leegwater*1,2, Bastiaan Kraaijenbrink3, Dirk Jan Moes4, Ilse Purmer5, Erik B. Wilms1,2

1 The Hague hospitals pharmacy, Den Haag, Netherlands, 2 Haga Hospital (Leyweg), Department of pharmacy, Den Haag, Netherlands, 3 Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands, 4 Leiden University Medical Center (LUMC), Department of Clinical Pharmacy & Toxicology, Leiden, Netherlands, 5 Haga Hospital (Leyweg), Intensive Care, Den Haag, Netherlands

Background: The pharmacokinetics of beta-lactam antibiotics are altered in critically ill patients. As a result of these alterations, conventional antibiotic regimens are insufficient to reach the pharmacodynamic target of 100% T>MIC. Ceftriaxone is a beta-lactam antibiotic with a long half-life. Because of the half-life the target T>MIC was assumed to be achieved with intermittent dosing. Nevertheless, increased clearance and reduced protein binding in critically ill patients may lead to insufficient exposure. Continuous infusion could therefore be supportive in reaching a T>MIC of 100%. However, no data comparing intermittent and continuous infusion of ceftriaxone are currently available.

Objective: To describe the population pharmacokinetics of ceftriaxone in critically ill patients when administered as intermittent or continuous infusion. To determine an optimized dosing regimen.

Materials/methods: A population pharmacokinetic study was performed in the intensive care unit of a tertiary teaching hospital. Patients were treated with ceftriaxone as continuous infusion or intermittent administration. A pharmacokinetic model was developed with non-linear mixed effect analysis. Subsequently, influential patient characteristics and dosing regimens were simulated with a Monte Carlo simulation to assess the probability of target attainment (PTA) of a T>MIC of 100% in intermittent and continuous dosing.

Results: 55 patients were included. The data were best described by a one-compartment model with linear elimination and non-linear saturable protein binding. The included covariates were: estimated creatinine clearance (CLcr), serum albumin concentration and intermittent or continuous infusion. The simulation results showed that 2 g/24 hours as intermittent infusion was only sufficient to reach a PTA of 90% for an MIC of 1 mg/l in patients with a reduced CLcr (0-60 ml/min). With continuous infusion of 2 g/24 hours a PTA 100% PTA was reached in all patients (CLcr 0-180 ml/min), in patients with an increased CLcr (120-180 ml/min), intermittent dosing of 2 g/24 hours and 2 g/12 hours were not sufficient to reach a PTA of > 90%.

Conclusions: Intermittent dosing of 2 g/24 hours ceftriaxone in patients with a normal or increased CLcr may lead to subtherapeutic exposure. Treating patients at risk with continuous infusion of 2 g/24 hours is superior to increasing the dose with intermittent infusion.

Orbitrap ultra high-resolution mass spectrometry proteomics data mirrors clinically relevant functional associations of black dematiaceous hyphomycetes (black yeast-like fungi)

Sybren De Hoog*,1,2; Alejandra Giraldo Lopez2; Ivan Moser1; Juha Knuuttila1; Joanna Freeke2,4; Azadeh Jamalian2,4; Benjamin Stielow2,4

1Radboud University Medical Center, Nijmegen, Netherlands, 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands, 3Thermo Fisher Scientific, Microbiology, Helsinki, Finland, 4Thermo Fisher Scientific, Microbiology Mass Spectrometry, Landsmeer, Netherlands

Background: Dematiaceous, or darkly pigmented fungi (namely black yeasts) are a large, phylogenetically heterogeneous group of organisms that have been associated with a wide variety of clinical syndromes. These are uncommon causes of human disease, but can be responsible for life-threatening infections in both immunocompromised and immunocompetent individuals. Due to rarity of many taxa in clinical practice, their (often) poorly defined and precise taxonomic assignment and the often inconsistently annotated clinical presentation makes affiliations of unknown strains often challenging. We present Orbitrap™ Mass Spectrometry data for a variety of genera and species and provide data for a remarkable association of functional traits (clinical presentation) in species that are genetically not related. Categorization of strains based on traits may appear highly useful when identification returns a rarely encountered microbial pathogen with unknown or poorly studied treatment options.

Materials/methods: High resolution accurate mass mass spectrometry was applied to >20 species of black yeasts with all strains being of clinical origin and obtained from pre-identified strain collections deposited at the Westerdijk Fungal Biodiversity institute, Utrecht, the Netherlands. Strains were characterised by means of standard molecular barcoding using multiple protein coding genes. Mass spectra were evaluated for the individual protein masses detected.

Results: A multi genera-species strain set comprising Cladophialophora, Exophiala, Fonsecea, S. stearothrix, Curvularia, Phaeoacremonium and Blastomyces were subjected to acquisition of Orbitrap™ mass spectrometry data. Species in black yeast-like fungi were functionally associated via different algorithmic approaches, mirroring their clinical presentation other than evolutionarily relatedness based on DNA sequences.

Conclusions: Inferring relationships between organisms and based on proteomic data which is conflicting traditionally derived classification schemes on the basis of DNA sequencing, can greatly widen our views on the evolution of microbial pathogenicity mechanisms. Associations based on traits that have functional meaning, were useful to categorize organisms according to disease outcome. Due to rarity of certain taxa in clinical practice, their (often) poorly defined and precise species identity and the often inconsistently annotated clinical presentation makes affiliations of unknowns based on traits highly useful when an identification results return a rarely encountered microbial pathogen with unknown or poorly studied treatment options.

Abstract 4368

Rapid increase of CTX-M-producing ST152 Shigella sonnei isolates in Switzerland

Edgar Campos-Madueno1, Odette J Bernasconi1, Carlo Lorenzo Casanova1, Maria Verena Elzi1, Carola Maffioli1, Thomas Bodmer1, Andreas Kronenberg1, Andrea Endimiani*1

1University of Bern, Institute for Infectious Diseases, Bern, Switzerland, 2MCL Medizinische Laboratorien, Bern, Switzerland, 3Labormedizinisches Zentrum Dr. Risch, Bern, Switzerland

Background: Shigella sonnei (Ss) is one of the most common causes of diarrhea in returning travelers and the emergence of antibiotic resistant strains is a matter of concern. Recently, the Swiss Centre for Antibiotic Resistance (ANRESIS) has noted a significant increase of third-/fourth-generation cephalosporin-resistant (3/4GC-R) isolates at national level. Here, we characterize a collection of Ss strains to better understand this phenomenon.

Materials/methods: So far, 25 Ss (of which 12 3/4GC-R) collected during 2017-2019 in Canton Bern have been analyzed. ASTs were performed using microdilution Sensititre panels. Whole-genome sequencing (WGS) was achieved using both Illumina and Nanopore and analyzed using the Center for Genomic Epidemiology platform. Sequence type (ST) was achieved using the E. coli MLST scheme. Plasmids and core genome analyses were also performed.

Results: According to the ANRESIS database, the national prevalence of 3/4GC-R Ss strains was 3.8%, 12.8%, 15.6%, and 38.5% in 2016, 2017, 2018, and 2019, respectively. The 3/4GC-R strains belonged to ST152 or, more rarely, to its single allele variant ST1503. The non-3/4GC-R belonged to different STs not included in clonal complex 152. The 3/4GC-R strains mainly carried \textit{bla}_{CTX-M-15} in IncFII or \textit{bla}_{CTX-M-3} in IncI1 plasmids. However, plasmids of same Inc group were not always similar to each other. Core genome analysis indicated that the ST152/1503 Ss strains were almost identical, with a limited number of different SNPs and allele matches >99%.

Conclusions: Our data indicate that the increase of 3/4GC-R Ss recorded by the national surveillance system (ANRESIS) is mainly due to the spread of a clone (ST152) producing CTX-M-3/-15. Although we cannot retrieve detailed epidemiological information from the laboratory databases, we noted that some strains were isolated from the stools of travelers returning from different countries. Therefore, we speculate that ST152 is a pandemic clone. In this context, we emphasize that this ST has been already reported in USA, Iran, Brazil, and we recently described a CTX-M-3 producer in Italy imported from Albania. Since Shigellosis is subject to mandatory declaration, an active collaboration with the Swiss Federal Office of Public Health could provide further key epidemiological data to better understand this concerning phenomenon.

Abstract 4369

**Antifungal susceptibility testing practices in mycology laboratories in France, 2018**

Anne-Pauline Bellanger¹, Florence Persat², Françoise Foulet³,⁴, Christine Bonnal⁶, Françoise Botterel⁴,⁵, Eric Dannaoui*⁵,⁷

¹Hôpital Universitaire Jean Minjoz, laboratoire de Parasitologie-Mycologie, Besançon, France, ²Hospices Civils de Lyon, laboratoire de Parasitologie-Mycologie, Institut des Agents Infectieux, Lyon, France, ³University Lyon 1, Villeurbanne, France, ⁴Hôpital Universitaire Mondor, laboratoire de Parasitologie-Mycologie, Créteil, France, ⁵EA Dynamyc UPEC, EnviA, USC Anses, Faculté de Médecine de Créteil, Créteil, France, ⁶Hôpital Universitaire Bichat, laboratoire de Parasitologie-Mycologie, Paris, France, ⁷Hôpital Européen Georges Pompidou, Unité de Parasitologie-Mycologie, Service de Microbiologie, Université Paris Descartes, Paris, France

**Abstract third-party references:** on behalf of the SFMM-AFST Study Group

**Background:** In vitro antifungal susceptibility testing (AFST) is important for therapeutic management of patients and to detect resistance. Commercial techniques are the most common AFST methods used by mycology laboratories. Nevertheless, the practices and potential difficulties encountered in their routine use are not well known.

**Materials/methods:** An online survey was performed to assess the practices of AFST in mycology laboratories in France. An electronic questionnaire was used for the survey. It consisted of 43 questions divided into 16 sections about the type of methods used, the strategy of antifungal testing, the way of reading the MIC, the interpretation of the MIC, the quality aspects, the technical aspects, the screening of resistance.

**Results:** The survey captured information from 45 laboratories (overall response rate of 94%). A large majority (77%) of the participating mycology laboratories (PML) performed AFST for more than 150 fungal isolates per year. The E-test was the most frequently used method (86%). For yeasts, 85% of PML tested a combination of four antifungal molecules [one echinocandin, fluconazole, voriconazole and amphotericin B]. A majority of PML declared reading the MIC results first at 24h of incubation, and then at 48h, both for Candida spp. (67%) and Aspergillus spp. (58%). Most of the PML (89%) used either an internal quality assessment (IQA) or an external quality assessment (EQA) and 62% used both IQA and EQA. Forty-six percent of the PML used the EUCAST clinical breakpoints (CBs), when available, to interpret the MIC values. Almost all the PML (98%) declared that the interpretation of MIC values was the main problem encountered during AFST and 40% reported difficulties in reading MIC values. Systematic screening of resistance was performed by very few PML (≈10%) in 2018.

**Conclusions:** A majority of French mycology laboratories routinely used E-test as AFST method, for both yeasts and filamentous fungi. If most parameters were similar between the 45 PML, two main problems emerged from this survey: reading and interpretation of MIC values. To homogenize AFST practices, detailed guidelines and instructions are needed, and could be implemented both by the manufacturer and by the French Society of Medical Mycology.

Abstract 4370

Species delimitation of clinically challenging fungi by Orbitrap ultra high-resolution mass spectrometry: a case study in Mucor, Rhizopus and Lichtheimia

Ivan Moser¹, Azadeh Jamalian*¹, ², Benjamin Stielow¹, ², Juha Knuuttila³, Alejandra Giraldo Lopez¹, Sybren De Hoog¹, ⁴, Joanna Freeke¹, ²

¹Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands, ²Thermo Fisher Scientific, Microbiology Mass Spectrometry, Landsmeer, Netherlands, ³Thermo Fisher Scientific, Microbiology, Helsinki, Finland, ⁴Radboud University Medical Center, Nijmegen, Netherlands

Background: The epidemiology of invasive fungal diseases due to filamentous fungi immunocompromised patients and other host groups is shifting with changing clinical practice. After Aspergillus, Mucorales (Zygomycetes) fungi are the next most commonest pathogens in patients with haematological malignancy, haematopoietic stem cell transplantation and solid organ transplantation. Additionally Mucorales infections are increasingly recognized in individuals with diabetes mellitus, after trauma or iatrogenic injury and have been associated to outbreaks following natural disasters (eg. by global climate change). We present ultra high resolution Orbitrap™ mass spectrometry data for the most relevant causative agents of Mucormycosis and their subsequent precise classification into the most up to date taxonomic entities. The presented data aims to provide an outlook on improved diagnosis to one of the most challenging fungal groups encountered in clinical microbiology.

Materials/methods: High resolution accurate mass mass spectrometry was applied to eight species of the genera Mucor, Rhizopus and Lichtheimia. Strains were all of clinical origin and obtained from pre-identified collections deposited at the Westerdijk Fungal Biodiversity institute, Utrecht, the Netherlands. Strains were characterised by means of standard molecular barcoding using multiple protein coding genes. The protein extracts from each strain were introduced to the mass spectrometer using electrospray ionisation (ESI). Mass spectra were evaluated for the individual protein masses detected. Different identification and algorithmic approaches were compared.

Results: With the described mass spectrometry method individual protein masses of a variety of classes were detected. Across the different fungal strains of the same species the variation in the presence of proteins enabled searching for species, lineage and strain specific protein masses that were used to delimit the tested entities.

Conclusions: The presented Orbitrap™ mass spectrometry identification assay was able to identify Mucormycosis causing agents, in a time efficient and effective and precise manner. Identification accuracy could not yet be obtained by conventional mass spectrometry approaches such MALDI-ToF, and demonstrates for the first time the application of a high resolution mass spectrometry technology to resolve effectively a notoriously difficult group of clinically relevant fungi in an easy way.

Persuading the prescriber: the impact of prospective audit with feedback on hospital antibiograms

Marianneta Chatzopoulou*, Argyrw Kyriakaki1, Lucy Reynolds2

1London School of Hygiene & Tropical Medicine, University of London, London, United Kingdom, 2Kapandriti Health Center, Department of Microbiology, Athens, Greece, 3London School of Hygiene & Tropical Medicine, London, United Kingdom

Background: Antimicrobial stewardship constitutes an essential element of any concerted effort to tackle rising trends of bacterial resistance. The term comprises variable strategies which aim to optimise prescribing practices through either mandatory antibiotic restrictions or prospective audits of prescriptions and subsequent feedback to clinicians. Although highly debated, the actual effect of the latter on hospital antibiograms has not been evaluated systematically. Therefore, the present study aims to review, collect and assess the available literature concerning the impact of persuasive stewardship strategies on antimicrobial resistance within hospital settings.

Materials/methods: A systematic literature review was conducted in the PubMed/Medline, Embase, Global Health and CINAHL Plus databases.

Results: Cluster randomised studies were absent and including observational designs in the dataset was the sole feasible option. Eight studies were included, seven simple before-and-after and one of an interrupted time series design. Frequency of audits and compliance rates varied within and between settings. The rationale of treatment optimization is not delineated in most cases rendering policy evaluation difficult. Overall, surveillance of sentinel microorganisms post-intervention indicates trivial results. Lack of proper theroretical reasoning causes uncertainty as to whether the few recorded successes are due to a causal effect or constitute random incidence fluctuations. The most straightforward and, thus, most informative approach targeted solely fluoroquinolone prescriptions and achieved improvements in relevant Pseudomonas susceptibilities as well as MRSA.

Conclusions: Research of higher standards is needed to address the actual effects of persuasive stewardship strategies on antimicrobial susceptibility patterns. At present, prospective audits with feedback seem inadequate to play a decisive role in bacterial resistance control within hospital environments

Recreational waters: a reservoir for Shiga toxin-producing Escherichia coli?

Louise O’connor1,2; Carina Brehony3; Brigid Hooban1,2; Kelly Fitzhenry1,2; Niamh Cahill1,2; Liam Burke*1,2; Paul Hickey4; Shane Keane4; Aine McNamara3; Martin Cormican1,2,5; Dearbhaille Morris1,2

1Antimicrobial Resistance and Microbial Ecology Group, School of Medicine, National University of Ireland Galway, Galway, Ireland; 2Ryan Institute, Centre for One Health, National University of Ireland Galway, Galway, Ireland; 3EUPHEM, HSE Dublin, Dublin, Ireland; 4Environmental Health Service, HSE West, Galway, Ireland; 5Health Service Executive, HSE West, Galway, Ireland

Abstract 4374

**Background:** Shiga toxin-producing *E. coli* (STEC) are pathogenic *E. coli* that can cause severe intestinal infection and haemolytic uremic syndrome (HUS) in humans, representing a major threat to public health. Since 2012, the notification rate of STEC in Ireland has been the highest in Europe. The aim of this study was to examine if recreational waters are a possible reservoir for STEC.

**Materials/methods:** Seawater (n=52), river (n=15) and lake (n=8) samples (30L) were collected from locations around Ireland between December 2018 and October 2019. Samples were processed using the CapE method and filters were enriched overnight in buffered peptone water. A boil-lysis was carried out on enrichment broth aliquots and extracts were tested using multiplex real-time PCR for *eae*, *vtx1* and *vtx2* genes. Positive samples were tested further for genes associated with serogroups O157, O26, O103, O104, O111 and O145.

**Results:** Of the 75 samples tested, 29/52 (56%) seawater samples, 14/15 (93%) river and 6/8 (75%) lake samples were positive for the *eae* gene and at least one of *vtx* genes. When these samples were tested further all samples were found to contain multiple serogroup gene targets. In seawater and lake samples the predominant serogroup was O103 and in river water samples it was O157. Two samples, both from fresh water sources were *vtx1/vtx2* positive but negative for *eae*.

**Conclusions:** To our knowledge this is the first investigation of multiple sites across Ireland for the presence of STEC in recreational waters. There was a high occurrence of STEC DNA in the samples tested, highlighting the need for further investigation to establish the scale of the problem. The findings indicate that there is a need to focus attention on the potential risk of infection from recreational waters where exposure is likely. It is worth noting that all of the seawaters tested were designated as good or excellent quality based on current EU bathing water monitoring criteria. This highlights the limitations of only assessing the total number of *E. coli* present as an indicator for quality without taking into consideration the pathogenicity of some variants.

Abstract 4375

Comparison of different sepsis scoring systems and pathways: qSOFA, SIRS, Shapiro Criteria and CEC SEPSIS KILLS pathway in bacteraemic and non-bacteraemic patients presenting to the emergency department

Rebecca Sparks*,1, Ruchir Chavada1, Christopher Trethewy2, Arisa Harada1

1Gosford Hospital, Gosford, Australia

Abstract third-party references: Department of Medicine, Gosford Hospital, Emergency Department, Gosford Hospital, Department of Microbiology and Infectious Diseases, NSW Health Pathology-Central Coast

Background: Bacteraemia is a major contributor to sepsis-related morbidity and mortality, with management focused on the early identification and treatment of these patients. However, prompt identification of bacteraemia has remained challenging. We designed this study to assess the performance of existing scoring systems and pathways - CEC SEPSIS KILLS pathway, quick sequential organ failure score (qSOFA), systemic inflammatory response syndrome (SIRS), the Shapiro criteria and the SEPSIS KILLS icon.

Materials/methods: This was a retrospective cohort study performed in two metropolitan hospitals in NSW. The first cohort included adult patients (>18 years) with positive blood cultures (bacteraemia with a true pathogen). The second cohort consisted of patients matched by age to the first without bacteremia. Performance of different criteria and pathway (sensitivity, specificity and mortality prediction) - qSOFA (≥2 criteria), SIRS (≥2 criteria), Shapiro criteria (≥1 major or ≥2 minor) and CEC SEPSIS KILLS pathway (BTF derangement +/- clinical concern), in the first 4 hours following ED triage was assessed.

Results: There were 251 patients in each cohort. When the Bacteraemic and Non-Bacteraemic cohort were compared using the scoring systems and pathways, the modified Shapiro criteria had the highest sensitivity (88%) with modest specificity (37.85%), and qSOFA had the highest specificity (83.67%) with poor sensitivity (19.82%). SIRS had reasonable sensitivity (82.07%), with poor sensitivity (20.72%). The CEC SEPSIS pathway sensitivity of 70.1% and specificity of 71.1%. The SEPSIS KILLS was activated on only 14% of bacteraemic patients.

Abstract 4376

**Identification of genetic factors increasing carbapenem resistance in Klebsiella pneumoniae with blaOXA-48**

Martina Cremanns*1, Sören G. Gatermann1, Niels Pfennigwerth1

1Ruhr-Universität Bochum, Department of Medical Microbiology, Bochum, Germany

**Background:** Carbapenemase-producing Enterobacterales became the most clinically significant multi-drug resistant bacteria. In Germany, *Klebsiella pneumoniae* with *bla*OXA-48 are most frequently detected, as shown in the annual reports of the National Reference Centre for Multidrug-resistant Gram-negative Bacteria (NRC). Although all carry *bla*OXA-48 some isolates show high resistance to carbapenems while some only show low minimal inhibitory concentrations (MIC) of carbapenems and are categorized susceptible according to EUCAST breakpoints. The aim of this study was to reveal possible genetic causations for varying MICs of carbapenems in *K. pneumoniae* expressing *bla*OXA-48.

**Materials/methods:** 20 Clinical *K. pneumoniae* isolates with *bla*OXA-48 showing low MICs of carbapenems were put under gradually rising selective pressure of meropenem during broth macrodilution to select for mutants with elevated MICs. Whole genome sequencing were performed with the low MIC primary isolates and the high MIC selected mutants to check for mutations. A hybrid assembly of Illumina MiSeq and Oxford Nanopore sequencing data was carried out to generate whole genome sequences.

**Results:** Mutations possibly leading to elevated MICs were predominantly found in genes of outer membrane proteins (OMP), as already described in the literature. But not in all isolates a insertion or mutation leading to an early abortion of OMP expression can be found. Ten of twenty selected mutants had an insertion element inserted within the *ompK36*-promoter, two had a complete deletion of OmpK36 and four had mutations within the *ompK36* gene, but there were also mutations in yet unsuspicous genes associated with OMP expression or proper folding.

**Conclusions:** There are only few single mutations having huge impact on the MICs of carbapenems in *K. pneumoniae* with *bla*OXA-48 as shown by sequencing data of clinical isolates and selected mutants. To further check if these mutations lead to elevated MICs of carbapenems they will be integrated into the primary clinical isolate genomes via CRISPR/Cas system. Clinical *K. pneumoniae* isolates with high MICs of carbapenems will be screened for the found or similar mutations in the same genes to check if *bla*OXA-48 or *bla*OXA-48 in combination with an mutation in an appropriate gene leads to high MIC in clinical isolates.

Abstract 4379

The mouse ear skin model reveals specific innate immune signatures into study of the dynamics of innate immune responses against to Staphylococcus aureus biofilms

Aizat Abdul Hamid1,2, Andrea Cara1, Alan Diot1, Jérome Josse1, Elisabeth Billard3, Frédéric Laurent2, Pascale Gueirard1

1Université Clermont Auvergne, Laboratoire Microorganismes : Génomique et Environnement, Clermont Ferrand, France, 2Université Claude Bernard Lyon 1, Centre International de Recherche en Infectiologie, Lyon, France, 3Université Clermont Auvergne, Laboratoire Microbes Intestin Inflammation et Susceptibilité de l’Hôte, Clermont Ferrand, France

Background: Staphylococcus aureus (SA) is a human pathogen that frequently causes nosocomial infections and infections on indwelling medical devices, mainly due to its capacity to shift between planktonic and biofilm lifestyles. Biofilm infections pose an important problem in human medicine, as they often lead to bacterial persistence and thus to chronic infections. Furthermore, they have been shown to be more resistant towards anti-infective agents and more importantly towards host immune cell attacks. In vivo, the bilateral interactions between biofilms and myeloid cells remain poorly studied and analysis of cell dynamics in tissues inoculated with biofilms is still an unexplored field. Thus, it is essential to design biologically sound in vivo experimental approaches aimed to extract specific immune signatures elicited by biofilms in order to develop alternative forms of therapies.

Materials/methods: Here, an in vivo transgenic mouse model is used in conjunction with intravital confocal microscopy, to study the dynamics of host inflammatory responses towards bacteria. We set up culture conditions to prepare calibrated inoculums of a red fluorescent strain of SA, in its planktonic or biofilm form. Then, we set up a confocal imaging acquisition and analysis protocol to study the recruitment of green fluorescent innate immune cells in the skin, specifically the mouse ear pinna of LysM-EGFP transgenic mice. These data were correlated with FACS analysis of recruited immune cells and quantification of bacterial load in target tissues (ear tissue, auricular lymph node).

Results: We show here that inflammatory responses to SA can be quantified over time, and that the dynamics of innate immune cells can be characterized. Our first results show that, despite being massively recruited in both cases, phagocytic cells have an attenuated capacity to infiltrate the injection site in the presence of biofilms and have an altered motility when compared to cells in the presence of planktonic bacteria.

Conclusions: We developed a mouse model of infection to compare the dynamics of inflammatory responses to planktonic or biofilm bacteria at the tissue and cellular level. The mouse ear pinna model appears to be a powerful imaging system to analyze the mechanisms of biofilm resistance to immune attacks.

Spontaneous and clinically relevant tet(A)-dependent tigecycline resistance development
Jennifer Jagdmann*1, Dan I. Andersson1, Hervé Nicoloff1
1Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden

Background: Overexpression of the tetracycline efflux pump tet(A) from Tn1721 in vitro has previously been shown to give increased resistance to the last-line, third generation tetracycline antibiotic tigecycline. We have previously discovered that spontaneous, high-frequency amplification of tet(A) in clinical Escherichia coli isolates leads to tigecycline resistance, but not in isolates with a 24-basepair deletion in the repressor protein tetR(A). We aimed here to study the effect of the frequent 24-nucleotide deletion on the expression of the efflux pump and on fitness. We also determined whether tet(A) could facilitate resistance development to the new tetracycline antibiotic omadacycline.

Materials/methods: Competitions of the wild-type tet(A) (tet(A)wt) and the tetR(A) 24-basepair deletion allele (tet(A)∆tetR) were performed in presence of tetracycline antibiotics (tetracycline, tigecycline, minocycline, and doxycycline) at varying concentrations. β-galactosidase assays were performed on the two tet(A) alleles and in presence of different concentrations of tetracyclines. Omadacycline MICs were determined by broth microdilution and DNA copy numbers were determined by qPCR.

Results: Competitions between strains carrying either tet(A)wt or tet(A)∆tetR showed that at high antibiotic concentrations, tet(A)wt gave a fitness advantage. At lower concentrations, there was either no difference in fitness between the two alleles, or a slight fitness advantage for tet(A)∆tetR. Neither allele appeared to be outcompeted by a strain devoid of tet(A). β-galactosidase assays showed that induction of tetA(A) was lower for the tet(A)∆tetR allele compared to tet(A)wt for all tetracycline antibiotics tested. Our simple PCR screening could accurately differentiate the different tetR(A) alleles. An increase in omadacycline MIC was observed for isolates carrying an amplification of tet(A)wt but not for isolates carrying an amplification of tet(A)∆tetR.

Conclusions: Expression of tetA(A) was decreased in the tet(A)∆tetR allele, thus explaining the inability of isolates carrying tet(A)∆tetR to develop tigecycline resistance. Maintenance of the tet(A)∆tetR allele in a population in absence and at low concentrations of tetracyclines might partially explain the high prevalence of the tet(A)∆tetR allele in E. coli. The tet(A)-associated tigecycline resistance development pattern appears to be similar for omadacycline. A simple PCR screen can identify the tet(A) allele and potentially aid in a clinical setting.

**Abstract third-party references:** American Type Culture Collection

**Background:** With over 2 million infections per year in the United States alone, antimicrobial resistance (AMR) among bacterial pathogens has become a serious threat to global health. In 2017, the World Health Organization (WHO) released a report to guide the direction of antimicrobial research and drug development that was designed to have a significant impact on public health; the criteria used to select pathogens included transmissibility and preventability, recent trends and prevalence of resistance, healthcare burden, and global mortality. A global panel of experts in infectious disease, antimicrobial resistance, drug development, and public health developed three tiers for the prioritization of pathogens: critical, high, and medium. To thwart the AMR threat via drug discovery and diagnostics research, accurate characterization of AMR gene clusters, mobile elements, insertions, and deletions in bacterial genomes is crucial. To that end, we developed the ATCC Global Priority Superbugs Collection, which comprises 57 fully authenticated, characterized, and sequenced strains representing critical level pathogens. Here, we discuss the phenotypic and genotypic characterization of these strains through antimicrobial susceptibility profiling and a standardized sequencing, assembly, and annotation pipeline.

**Materials/methods:**

**Results:**

**Conclusions:** Genotypic and phenotypic characterization of antimicrobial-resistant priority pathogens is beneficial for studies involving epidemiology, antimicrobial resistance mechanisms, and drug development. To support this need, strains in the ATCC Global Priority Superbugs collection are provided with:

- Susceptibility data – MIC values and susceptibility profiles for targeted drugs.
- Genetic data – Complete genome sequence, antibiotic resistance genes and 16S rRNA genes.
- Source information – Geography, collection date, patient age and gender, and collection site.

Abstract 4383

Diverse populations of carbapenem-resistant Klebsiella pneumoniae isolated in rectal colonisation cultures from intensive care units of a single tertiary centre in Greece

Efthymia Protonotariou*1, Charalampos Kotzamanidis2, Theofilos Papadopoulos3, Dimitrios Pilalas4, Areti Tychala15, Dimitra Papadopoulou1, Fotini Netsika1, Georgios Meletis1, Antonios Zdragas2, Metallidis Symeon1, Lemonia Skoura1

1AHEPA University Hospital, Department of Microbiology, Thessaloniki, Greece, 2Greek Agricultural Organisation-DIMITRA, Veterinary Research Institute of Thessaloniki, Themi, Greece, 3Aristotle University of Thessaloniki, School of Veterinary Medicine, Department of Microbiology and Infectious Diseases, Thessaloniki, Greece, 4AHEPA University Hospital, Medical School, Aristotle University of Thessaloniki, First Propedeutic Department of Internal Medicine, Thessaloniki, Greece, 5Thessaloniki Psychiatric Hospital, Department of Microbiology, Stavroupoli, Greece, 6AHEPA University Hospital, Department of Infectious Diseases, First Department of Internal Medicine, Thessaloniki, Greece

Background: Colonized patients with carbapenem-resistant Enterobacterales, especially those admitted to intensive care units (ICUs), are considered at high risk for developing serious infections. The aim of our study was to describe the epidemiology of rectal colonization by carbapenemase-producing Klebsiella pneumoniae (CPKP) among inpatients in the intensive care units (ICUs) in a University Hospital in Thessaloniki-Greece and to identify possible epidemiological links using molecular techniques.

Materials/methods: A total of 45 CPKP were randomly selected among isolates collected from fecal samples of 45 inpatients performing active rectal screening for multidrug-resistant Enterobacterales during hospitalization in the three ICUs of AHEPA University Hospital during a two-year period (2016-2018). Bacterial identification and susceptibility testing were performed by the automated system VITEK2 (bioMérieux, France). Carbapenem-resistant isolates were phenotypically screened for the presence of MBL, KPC or both carbapenemases with a combined disk test using meropenem disks with and without carbapenemase inhibitors (EDTA and phenyl-boronic acid). The presence of carbapenemase-encoding genes was further confirmed by PCR. XbaI-PFGE typing was used to subtype the isolates and identify possible epidemiological links. A database containing all the PFGE patterns was created using the Bionumerics software. Cut off value for cluster determination was set to 90%.

Results: The patient median age was 59 (17-87) years; 27 were male. blaKPC gene was detected in 35 (78%) of the isolates while 8 (18%) of them harbored blaVIM and 9 (20%) blaNDM suggesting the different mechanisms for strains resistant to carbapenems. The 45 CPKP isolates could be assigned to 37 PFGE patterns and 20 PFGE clusters. Dominant PFGE clusters were not detected; only eight strains isolated from different ICUs were assigned to a specific cluster, indicating heterogeneity of strains circulating in the hospital wards during the study period.

Conclusions: The detection of multiple clones of CPKP colonizing patients in the ICUs of our hospital and the risk for infection they present pose challenges for infection control in a setting with shortage of ICU beds. Furthermore, it creates an environment where bacteria may accumulate different mechanisms of resistant. Further study is required to determine the molecular epidemiology of CPKPs in our setting.
**Pathogenic potential and antimicrobial resistance genomic analysis of human gut commensal Escherichia coli**

Babak Pakbin1,2, Paola Lisotto1, Erwin G. Raangs3, Alexander W. Friedrich3, John W. A. Rossen3, Silvia García Cobos4,*

1Faculty of Veterinary Medicine, University Of Tehran (FVM-UT), Tehran, Iran, 2University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 3University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 4Reference and Research Laboratory on Antimicrobial Resistance and Healthcare-associated infections, National Microbiology Center, Institute of Health Carlos III, Majadahonda, Spain

**Background:** Gut commensal Escherichia coli (gCEC) can cause extraintestinal infections in elderly or immunocompromised patients. Sometimes these bacteria cannot be distinguished from extraintestinal pathogenic E. coli (ExPEC) by molecular epidemiological approaches, although their genotypes and virulence content may differ. Here we analyzed gCEC genomes from healthy people to investigate their pathogenic potential and phylogeny.

**Materials/methods:** Forty-eight E. coli isolated from faeces (nT=47, two isolates from the same sample had a different susceptibility pattern) from a healthy cohort (2014, Lifelines, the Netherlands) were sequenced in a NextSeq 500 Illumina instrument, 2x150bp paired-end reads. Reads were trimmed and de-novo assembled (CLCbio). We analyzed the genomes to gather information on virulence factors (VFs) associated to ExPEC and intestinal pathogenic E. coli (EnPEC) (Abricate), CRISPR-Cas system content (CRISPRCasFinder), which limits acquisition of foreign DNA, antimicrobial resistance genes (ResFinder) and molecular typing (phylogroup, serotype, MLST and cgMLST using SeqSphere).

**Results:** One isolate (B2-unknown ST, O84:H2) harboured a verocytotoxin vt1 gene considered for enterohemorrhagic E. coli (EHEC). The remaining isolates (97.9%) had either uropathogenic E. coli (UPEC) and/or neonatal meningitis E. coli (NMEC) associated genes. Fifty percent of isolates had between 11-16 of the 27 specific ExPEC genes investigated. The most prevalent genes were related to adherence (ibeA, 97.9%;aslA, 91.7%;fimA, 100%), protection (iss, 70.1%;kpsM, 58.3%) and iron-acquisition functions (chuA, 89.5%). All isolates harboured CRISPR arrays in which 56.3% (27/48) had a Cas protein cluster [41.7% I-E subtype, 12.5% I-F subtype and 2.1% both subtypes]. The number of CRISPR repeat units varied between 1 to 10. The most common phylogenetic group was B2 (39.6%). We observed 35 different MLST-STs, ST73 (10.4%) being the most abundant and all isolates had more than 41 allele differences by cgMLST analysis. Isolates were resistant to ampicillin (10.4%) -blaTEM-1B, 1C, 1D genes-, amoxicillin and amoxicillin-clavulanic acid (20.8%), cefuroxime (2.1%) and trimethoprim-sulfamethoxasol (10.4%).

**Conclusions:** The studied human gCEC isolates were genetically very diverse and could be potential extraintestinal pathogens due to the presence of associated VFs. A low number of CRISPR repeat units has been previously associated with the presence of a higher number of VF.

Abstract third-party references: This work was partly supported by the High Level-Hospital Program, Health Commission of Guangdong Province, China (HKUSZH201902012) High-Level Hospital Development Scientific Research Nurturing Program of The University of Hong Kong–Shenzhen Hospital, China as well as the Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Ministry of Education, China.

Background: Amongst the list of >360 Aspergillus species, A. fumigatus, A. flavus, A. terreus and A. niger are the predominant species that cause human infection, but the clinical spectrum of Aspergillus infections has progressively diversified, largely due to the advancement of molecular technologies, which revealed numerous clinical isolates to be cryptic species. Currently, there is a lack of knowledge on the types of disease that these cryptic species cause. Moreover, these cryptic species may exhibit dissimilar antifungal susceptibilities to the four predominant Aspergillus species.

Materials/methods: All Aspergillus strains isolated in this study were recovered from clinical specimens from five hospitals in Hong Kong, Shenzhen and Shanghai. Sequencing of two long-established markers, beta-tubulin and/or calmodulin genes was performed to ensure accurate species identification. Antifungal susceptibility testing was performed to investigate the susceptibility pattern of these cryptic species against 10 antifungal agents by the EUCAST reference protocol.

Results: During 2012–2018, 21 clinical strains from 21 patients aged 26-78 years [male:female ratio = 2:1] were found belonging to twelve cryptic Aspergillus species (A. tubingensis [n = 4], A. caelatus [n = 3], A. amoenum [n = 2], A. brunneoviolaceus [n = 2], A. sydowii [n = 2], A. tamarii [n = 2], A. aculeatus [n = 1], A. ostroafricanus [n = 1], A. nidulans [n = 1], A. neoniger [n = 1], A. quadricirratus [n = 1], A. welwitschiae [n = 1]). Sixteen of the patients (76.2%) were burdened with underlying disease related to chronic respiratory diseases [56.2%]. Infection manifested as a broad-spectrum of diseases mainly comprising of chronic pulmonary aspergillosis [33.3%], chronic otitis media [9.5%], invasive aspergillosis [9.5%], wound infection [9.5%] and onychomycosis [9.5%]. Susceptibility testing showed elevated azole MICs for A. tubingensis and A. neoniger (isavuconazole: 2 to >16 mg/L; voriconazole: 2 to >16 mg/L; itraconazole: 1 to >8 mg/L; posaconazole: 0.125 to 2 mg/L).

Conclusions: Our results demonstrated a diverse spectrum of cryptic Aspergillus species infection and the potential emergence of antifungal resistance. Accurate identification of clinical Aspergillus isolates and in vitro antifungal susceptibility testing are crucial for better patient management.

Abstract 4386

Suspected reverse zoonosis of influenza A(H1N1)pdm09 virus infection found in Ailuropoda melanoleuca in Hong Kong Oceanarium

Chun Ho Chang*,1, Yik Hei Fong1, Jade Li Teng1, Susanna K. P. Lau1, Patrick C. Y. Woo1

1Department of Microbiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong

Background: We confirmed a case of pH1N1 infection in an Ailuropoda melanoleuca (giant panda) kept in an oceanarium of Hong Kong in 2019. The panda developed clinical signs suggestive of respiratory infections, including nasal discharge, loss of appetite and fatigue, and was nonfebrile throughout. Complete blood picture two days after symptom onset shows significant leucocytosis. Eventually, symptoms completely resolved on day 8.

Materials/methods: Nasal swab specimens were collected in 1 mL of phosphate-buffered saline for virologic studies. Investigation of the specimens was carried out for identification of causative pathogen. Rapid antigen detection and reverse transcription PCR (RT-PCR) were performed to identify the presence of influenza A virus. Real-time RT-PCR targeting the M gene was used to monitor the daily change in viral load. Cytopathic effect of the virus was studied using cell culture inoculated with the specimen. The entire viral genome was obtained for sequence analysis. Subsequent phylogenetic studies were carried out by analysing the sequences of surface glycoproteins of the isolate.

Results: Viral detection showed positive result for influenza A and RT-PCR confirmed the findings. Viral load displayed a descending trend from 6.00 log_{10} copies/mL upon symptom onset to undetectable level four days later. Phylogenetic analysis of the entire genome revealed that the isolated strain has close relation with other known pH1N1 viruses prevalent in Hong Kong previously. In particular, this strain was most closely related to the most prevalent strain within the region when the giant panda was infected, with genetic difference of two bases.

Conclusions: Study on the phylogeny of the isolated pH1N1 strain revealed close relation with other human strains. The infection is thus possible to be originated from infected humans during the influenza season. Handlers of animals are of the greatest risk of reverse zoonosis. They should pay close attention to the prevention of transmitting infectious diseases to animals. More results will come into light as the origin of infection will be tracked in the upcoming phase of the study. Handlers of the giant panda and other animals in the proximity will be screened for influenza virus, regardless of the presence of respiratory symptoms.

Evaluation in general practice of the patient’s feelings about a recent hospitalisation and isolation for a multidrug-resistant infection

Ophélie Hereng1, Aurélien Dinh1, Simon Bessis1, Soline Siméon1, Morgan Matt1, Benjamin Davido*1

1Hopital Raymond Poincaré, Garches, France

Background: Isolation precautions used against multidrug-resistant (MDR) organisms are responsible for many emotional side effects. We evaluated patient’s feeling after a hospitalization for an MDR infection. Deciphering patients’ emotions might help provide better answers to latent and shameful questions.

Materials/methods: We conducted a qualitative study that included 11 interviews from August 2017 to June 2018 of patients previously hospitalized and placed in isolation precautions in a single occupancy room in an infectious disease ward. We used phenomenology and verbatim transcription analysis was performed using NVivo software.

Results: Participants consisted of 3 women and 8 men. Median age was 58 (26-81) years. Median duration of hospitalization was 10 (5-21) days. Patients had been previously infected by an ESBL urinary tract infection including 3 pyelonephritis, 2 epididymitis, 4 cystitis complicating a neurologic bladder, and 1 MRSA osteomyelitis. One patient experienced a skin and soft tissue infection due to a K pneumoniae OXA-48. Median duration of the interview was 12 minutes, 8 seconds, ranging from 10.10-32.35 seconds.

No interview was interrupted by any participant. Median time between discharge from the hospital and the interview was 12 weeks (4-13). Participants were mainly convinced that the infection was strongly linked to the hospital and considered it as nosocomial that led to anxiety, especially regarding the origin of the infection and the absence of formal source of infection. Also they expressed fears of contagion to their close surroundings therefore the patient is willing to “be free from carriage” and is self-questioning about limitation or therapeutic arsenal in the future.

Conclusions: MDR infections are negatively impacting patient’s lived experience even after hospital discharge, partly owing to prior implementation of isolation precautions. We need to improve communication between specialists and general practitioners to reassure the patient and his surroundings regarding the anxiety resulting from such hospitalization.

Direct detection of extended-spectrum beta-lactamases in bacteria isolated in blood culture bottles using a lateral flow assay

Genoveva Cuesta Chasco*1, Jordi Bosch1;2;3, Yuliya Zboromyrska1, Cristina Pitart1;3, Andrea Vergara1, Francisco Javier Morales1, Elisa Rubio Garcia1, Berta Fidalgo1, Mariana José Fernández1, Climent Casais-Pascual1;2;3, Jordi Vila Estape1;2;3

1Hospital Clínic de Barcelona, clinical microbiology department, Barcelona, Spain, 2ISGlobal, Barcelona, Spain, 3University of Barcelona, Barcelona, Spain

Background: Rapid identification and susceptibility testing of bloodstream infection pathogens remain a crucial step in the early effective therapy, especially for patients with sepsis, causing high morbimortality and medical costs. Traditional methods require at least one day for susceptibility testing results. We evaluated the use of a lateral flow assay - which includes NG-test Blood Culture Prep (NGBCP) and NG-Test CTX-M MULTI Lateral Flow Test (LFT) NGbiotech® - for the detection of extended spectrum beta-lactamase (ESBL) directly from positive blood cultures.

Materials/methods: A total of 48 blood cultures positive for Enterobacterales were included in the study: 28 positive for ESBL producing strains (18 Escherichia coli and 10 Klebsiella pneumoniae) and 20 non-ESBL producing strains, which included 16 third-generation cephalosporin susceptible strains (11 E. coli, 2 K. pneumoniae, 2 K. oxytoca and 1 K. variicola) and 4 third-generation cephalosporin resistant strains due to mechanisms other than ESBL (1 E. coli, 1 K. pneumoniae and 2 K. aerogenes). Species identification was performed with direct MALDI-TOF. Blood culture vials positive for Gram-negative bacilli were stored at 4°C until antimicrobial susceptibility testing were available. Only one vial from each patient was used for NGBCP+LFT. The procedure was: 1 mL of positive blood culture was mixed with 1 mL of lysis buffer, vortexed 20 seconds, centrifuged 1 minute/15000 rpm. The pellet was resuspended with 1 mL of wash buffer, vortexed 20 seconds, centrifuged 1 minute/15000 rpm. The pellet was resuspended with 5 drops of extraction buffer to perform the LFT.

Results: Test protocol (NGBCP+LFT) and results in the Figure.

</tbody>
</table>

Sensitivity and specificity of the protocol for ESBL detection directly from positive blood cultures were 92.8% and 100%, respectively. The protocol turnaround time was one hour.

Conclusions: ESBL detection time from positive blood culture samples was reduced from one day to one hour using the described protocol. The NGBCP allows standardized sample preparation compared to in-house protocols. The reduced sensitivity was probably due to insufficient bacterial load obtained from positive blood cultures in two samples.

Mouse colonisation by multidrug-resistant *Escherichia coli* in the absence of antibiotic selection

Chris Connor*1, Amanda Zucoloto2, Ianling Yu2, Braedon Mcdonald2, Alan Mcnally1

1University of Birmingham, Institute of Microbiology and Infection, Birmingham, United Kingdom, 2University of Calgary, Calgary, Canada

**Background:** Antimicrobial resistance (AMR) is a growing health concern with pathogenic bacteria becoming increasingly resistant to clinically used antibiotics. *E. coli* account for a significant proportion of these multi-drug resistant (MDR) infections. Of particular note is *E. coli* ST1 31 which has established itself as a globally dominant MDR clone. It is unclear what has permitted this particular clone to spread so effectively. Moreover, traveller surveillance studies have indicated that MDR bacteria are capable of colonising healthy individuals in the absence of antibiotic treatment. It is therefore clear that there are additional factors controlling the spread of AMR. Here we present data illustrating the ability of *E. coli* ST131 to outcompete and displace commensal bacteria in a germ-free mouse model.

**Materials/methods:** Germ free C57/B16 mice were colonised with bacteria via oral gavage of 10⁹ CFU. For competition experiments mice were colonised with 5 x10⁸ of each strain. For displacement and co-housing strains mice were colonised for one week before challenging with a second strain or co-housing. Colonisation was monitored by CFU counts from faecal pellets for between 1 and 4 weeks. Specific strain composition at select timepoints was confirmed by qPCR. Host inflammatory response was measured by histology and cytokine mRNA profiling.

**Results:** All bacterial strains used were able to colonise germ-free mice and were stable for up to 4 weeks. When co-gavaged in a 1:1 ratio the MDR ST73 and ST131 strains were able to outcompete the commensal ST10. One day subsequent to gavage the MDR strains were dominant accounting for greater than 50% of the bacterial load. The ST131 strain achieved near 100% dominance by day 4 compared to ST73 at day 6. Furthermore both ST73 and ST131 are capable of displacing a resident ST10 commensal strain. Displacement occurs both when challenging bacteria are gavaged and when mice are co-housed. ST131 produced a bacterial ‘bloom’ in the first 5 days of challenge.

**Conclusions:** MDR strains are capable of out-competing commensals when co-gavaged into mice. Moreover, MDR strains are able to dominate over resident commensals. In both instances there was no antibiotic mediated selection.

Clinical impact of infections caused by carbapenemase-producing Enterobacteriaceae
Laura Corbella Vazquez* 1, Mario Fernandez Ruiz 2, Maria Ruiz-Ruigómez 1, Isabel Rodriguez Goncera 1, Jose Tiago Sequeira 1, Francisco Lopez-Medrano 1, Maria Pilar Hernandez Jimenez 1, Manolo Lizasoain 1, Jennifer Villa 3, Jose M. Aguado Garcia 1, Rafael San Juan Garrido 1

1Unit of Infectious Diseases. University Hospital 12 de Octubre, Instituto de Investigación Hospital “12 de Octubre” (imas12), Madrid, Spain, 2Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain, 3Unit of Microbiology, University Hospital 12 de Octubre, Instituto de Investigación Hospital “12 de Octubre” (imas12), Madrid, Spain

Background: Carbapenemase-producing Enterobacteriaceae (CRE) infections cause major morbidity. Most previous studies were designed to detect risk factors for developing CRE infections. Nevertheless, the clinical impact of carbapenem resistance once adjusted by potential confounders remains uncertain.

Materials/methods: We performed a retrospective observational study including all episodes of CRE-infection at our institution between 01/06/2013 and 31/12/2016. A comparative cohort of infection due to non-CRE Enterobacteriaceae was assembled by matching each episode by clinical syndrome, previous manipulation and admission department. The primary outcome was clinical failure (composite of lack of clinical cure, clinical and/or microbiological recurrence and all-cause 30-day mortality), whereas 30-day attributable mortality was considered as secondary outcome.

Results: We included 334 episodes of infection (167 CRE and 167 non-CRE). Most common clinical syndromes were urinary tract infection (47.3%), surgical site infection (24%), respiratory tract infection (24%), catheter-associated bacteremia (8.4%) and intraabdominal infection (7.2%). Bacteremia was present in 76 episodes. Baseline characteristics were similar between both groups except for previous renal replacement therapy (16.2% vs. 8.0%; p=0.030). Clinical failure at 30 days was 47.3% for CRE-infection and 22.8% for non-CRE-infection (unadjusted hazard ratio [HR]: 2.017; 95% confidence interval [CI]: 1.370 – 2.970; p <0.0001). 30-day attributable mortality was 22.2% for CRE-infection and 7.2% for non-CRE-infection (unadjusted HR: 3.325; 95% CI: 1.730 – 6.391; p <0.0001). After including several variables in a Cox regression model to evaluate clinical failure (McCabe and age-adjusted Charlson scores, renal replacement therapy, cumulative days of hospitalization during actual admission, Pitt bacteremia score, source control, appropriate therapy within 72 hours from the onset of symptoms, and use of potentially nephrotoxic antibiotics), CRE-infection remained as an independent risk factor (adjusted HR: 1.862; 95% CI: 1.150 – 3.013; p=0.011). In addition, CRE-infection was also predictive of 30-day attributable mortality after adjusting for previous renal replacement therapy, Pitt score, source control, appropriate therapy within 72 hours and use of nephrotoxic agents (adjusted HR: 3.273; 95% CI: 1.675 – 6.396; p=0.001).

Conclusions: After matching by baseline characteristics and adjusting for potential clinical confounders, infections caused by CRE had higher 30-day rates of clinical failure and attributable mortality than episodes caused by carbapenem-susceptible microorganisms.

Impact of multidisciplinary management on the outcome of aortic prosthetic vascular graft infections: a retrospective, single-centre experience

Mathilde Puges*1, Aurélie Cluzeaud2, Charles Cazanave1, Vincenzo Brizzi2, Caroline Caradu2, Eric Ducasse2, Xavier Bérard2

1Bordeaux University Hospital, Infectious Diseases Department, Bordeaux, France, 2Bordeaux University Hospital, Vascular Surgery Department, Bordeaux, France

Background: Aortic prosthetic vascular graft infection (PVGI) is a rare (up to 5%) but devastating complication in vascular surgery, burdened by high mortality and reinfection rates. Aim of this study was to evaluate the impact of a multidisciplinary management on the outcome of aortic PVGI in terms of morbidity and mortality.

Materials/methods: A monthly meeting dedicated to vascular infections has been set up in Bordeaux University Hospital since April 2011. In these meetings, infectious disease physicians, vascular surgeons, nuclear medicine physicians, microbiologists, and anaesthesists discuss about the management of all patients suffering from a vascular graft infection in our centre, in order to propose a tailored treatment strategy and to improve the prognosis of these severe infections. Patients treated in our unit for aortic PVGI infection from January 2004 to July 2018 were retrospectively reviewed and divided in two groups: period 1, P1 (from 2004 to April 2011) and period 2, P2 (from April 2011 to 2018). Mortality and reinfection rates were the primary outcomes and were calculated using Kaplan-Meier curves. Log-Rank test was used to compare the two groups.

Results: A total of 92 patients (87 males, mean age: 64 years old) were included, 31 patients during P1 and 61 during P2. Demographic and baseline disease characteristics were comparable between groups. Mean delay between index surgery and PVGI surgical treatment was six years. For each period, 21% of patients underwent an emergent surgical treatment. A conservative treatment without surgery was performed in four cases during P2. More complete excisions (48% vs 51.7%) and more revascularisation using cryopreserved allograft (0 vs 19%) were performed during P2. Mean follow-up was 4.9 and 1.2 years for P1 and P2, respectively. In-hospital mortality rate was 32.3% and 21.3% during P1 and P2, respectively. Median reinfection delay was 7.5 months. Reinfection rate was significantly reduced in P2 (47.6% vs 12.5%, p=0.02). The 2-years survival rate was 54.6% and 69%, during P1 and P2, respectively.

Conclusions: Multidisciplinary management seems to provide better results for aortic PVGI management and reduces in-hospital mortality and reinfection rates.

Abstract 4394

Delamanid in MDR/XDR pulmonary tuberculosis in Russia: first experience
Andrey Maryandyshev, Suleiman Lorsanov, Zarema Khaidarkhanova, Dmitry Perkhin, Oxana Sveshnikova, Anastasia Gaida, Elena Khimova, Vladislav Privolnev
Northern state medical University, Arkhangelsk, Russian Federation, Respublican TB hospital, Grozny, Russian Federation, Arkhangelsk clinical TB dispensary, Arkhangelsk, Russian Federation, R-Pharm Medical Department, Moscow, Russian Federation

Background: Delamanid is not approved in Russia. MSF made supply of delamanid for 2 cities.

Materials/methods: In 2015-2019 delamanid was used for 48 MDR/XDR patients. 25% were females. The age was 44.87±14.38. Forty-three (89.6%) patients had caverns. Patients’ profiles: failure of previous therapy 26(54.2%), interruption of previous treatment - 12 patients (25%), a new case - 6 (12.5%), relapse - 4 (8.3%) patients. HIV was observed in 4 (8.3%) people. Hepatitis B was in 5 (10.4%), hepatitis C in 12 (25%), both in 4 (8.3%) people, combination of 3 diseases in 1 patient. Delamanid administrated with linezolid and/or clofazimine. 22 (45.8%) patients received bedaquiline. Therapy of MDR and pre-XDR resistant to injectable aminoglycosides included levofloxacin, linezolid, clofazimine. Some XDR cases included imipenem and amoxicilline/clavulanate. Safety monitoring of clinical symptoms was performed daily, laboratory and instrumental control monthly.

Results: Positive smear microscopy was in 37 (77.1%). Resistance: MDR – 11 (23%), pre-XDR-FQ – 3 (6%), pre-XDR-AMG – 11 (23%), XDR – 23 (48%) patients. The sputum culture conversion after 6 months achieved in 22 (45.8%) patients in period from 32 to 241 (average 107) days. Delamanid administrated on an average of 223.9 days. Treatment success after 4 years follow up was registered in 68.7%. Lost of observation – 5 (10.4%) patients. Ineffective treatment - 4 (8.3%) patients. Six (12.5%) died of tuberculosis during treatment. Two (4.1%) continue to have positive culture and treatment till now. 13 (27.1%) died including 9 deaths form tuberculosis. Adverse events did not required the cancellation of delamanid or change of treatment. 12 (25%) patients had QTcF prolongation, 1 patient more 500 ms normalized with no treatment. Other adverse events: increased liver enzymes, thrombocytopenia, anemia, peripheral neuropathy, dermatitis, vomiting, heart pain, cardiomyopathy, edema of the extremities. All cases did not result in the cancellation of delamanid.

Conclusions: Delamanid in combination therapy showed a good result of treatment and good safety among the most complex MDR/XDR patients with ineffective and interrupted previous course of treatment, co-infected HIV, hepatitis B and C. The combined use of delamanid, bedaquiline, linezolid, clofazimine for XDR did not lead to serious adverse events.

Variations in antibiotic prescribing among village doctors in rural Shandong province, China

Oliver J. Dyar1*, Yang Ding2, Yin Jia2, Sun Qiang2, Cecilia Stålsby Lundborg1

1Karolinska Institutet, Stockholm, Sweden, 2Shandong University, Jinan, China

Abstract third-party references: On behalf of the IMPACT consortium

Background: Understanding variations in antibiotic prescribing at the prescriber-level can be valuable for exploring barriers and facilitators to rational antibiotic use, as well as for enabling individualised feedback on prescribing practices. We assessed variation in antibiotic prescribing among village doctors in rural Shandong province.

Materials/methods: Prescriptions were collected retrospectively over a 2.5 year period at eight village clinics located around a single town. A target of 60 prescriptions per month were included from each clinic, from an average total of 300. Diagnoses were coded according to the International Classification of Diseases, 10th Revision and prescribed antibiotics were coded according to the Anatomical Therapeutic Chemical classification system. Prescriptions were analysed at the aggregate level and at the individual-prescriber level, with a focus on diagnoses of likely viral acute upper respiratory tract infections [AURI], defined as J00 [acute nasopharyngitis [common cold]] and J06.9 [acute upper respiratory infection, unspecified].

Results: In total 14471 prescriptions from 23 prescribers were included, of which 5833 (40.3%) contained at least one antibiotic. A total of 5177 prescriptions were categorised as likely viral AURI, and 62.5% (3237/5177) of these included an antibiotic, accounting for 55.5% (3237/5833) of all antibiotic-containing prescriptions. At the individual prescriber-level there was very wide variation in the antibiotic prescribing rate for likely viral AURI [33.1% to 88.0%], as well as the multiple antibiotic prescribing rate [1.3% to 60.2%] and injectable antibiotic prescribing rate [3.2% to 62.1%], see Figure. Each doctor prescribed between 11 and 21 unique agents for the single diagnosis of AURI, including many broad-spectrum antibiotics. Doctors in the top quartile for antibiotic prescribing for AURI also had higher antibiotic prescribing rates for potentially bacterial upper respiratory tract infections [pharyngitis, tonsillitis, laryngopharyngitis] [92.7% vs. 72.4%, p<0.05] and for gastritis, gastroenteritis and diarrhoea [88.8% vs. 76.2%, p<0.05] compared with doctors in the lowest quartile for antibiotic prescribing for AURI.

Conclusions: All prescribers showed evidence of over-using antibiotics for respiratory tract infections. Variations in individual prescriber practices are significant even in a small homogenous setting in rural China, and these must be accounted for when developing targets and interventions to improve antibiotic use.

Abstract 4399

**Effect of rapid influenza detection tests on antibiotic prescriptions**

Aimé Berwa*1, Meghann Gallouche2, Sylvie Larrat2, Jérôme Fauconnier2, Jean Luc Bosson1, Caroline Landelle1

1Grenoble-Alpes, Centre Hospitalo-Universitaire Grenoble-Alpes, La Tronche, France, 2Grenoble-Alpes, Centre Hospitalo-Universitaire Grenoble-Alpes, La Tronche, France

**Background:** Antibiotic misuse is common among patients with influenza like illness (ILI), contributing to the emergence of multidrug resistant bacteria. Our primary objective was to evaluate whether the deployment of rapid PCR tests for detection of influenza viruses could lead to a decrease in antibiotic prescriptions, in comparison with classic tests. The impact of rapid tests on prescription of biological tests, X-rays and oseltamivir; hospitalizations and length of stay (LOS) was also evaluated.

**Materials/methods:** Data from patients with ILI at the emergency department (ED) of Grenoble-Alpes University Hospital were retrospectively collected over three influenza seasons: in 2016/2017 and 2017/2018 when classic influenza tests were used (Rapid RT-PCR Genexpert® [Cepheid] and RT-PCR R-DiaFlu® [Diagenode Diagnostics]), and in 2018/2019 when rapid influenza tests were used (Cobas® Liat System [Roche Diagnostics]). The primary outcome was antibiotic prescription (any versus none). A bivariate analysis compared antibiotic prescriptions between the seasons; a multivariate analysis assessed the association between influenza seasons and antibiotic prescriptions, adjusting for age, sex, influenza test result and hospitalization after ED stay. Ancillary testing (complete blood count, blood chemistry, c-reactive protein, procalcitonin [PCT] and blood culture), chest X-ray and oseltamivir prescriptions were also compared, along with hospitalizations after ED stay and LOS at the ED.

**Results:** Among 1,849 patients included, 620 had a positive influenza test result. The number of antibiotic prescriptions was significantly different between the 3 periods in the bivariate analysis (31.1% in 2018/2019 vs 44% in 2017/2018 and 48.3% in 2016/2017, p<0.0001) and in the multivariate analysis (Odds Ratio [OR]=0.48, IC95%=0.30-0.76 for 2018/2019 and OR=0.99, IC95%=0.67-1.46 for 2017/2018, in comparison to 2016/2017). There were significantly fewer prescriptions of biological tests (except PCT and blood cultures), fewer X-rays and fewer hospitalizations in 2018/2019, in comparison with the 2 previous seasons. There were significantly more oseltamivir prescriptions in 2018/2019. LOS was not significantly different.

**Conclusions:** Introducing rapid influenza tests in the ED seems to decrease antibiotic use and leads to less ancillary testing, X-rays and hospitalizations among patients with ILI. However, medico-economic studies are now necessary before a definite recommendation.

Abstract 4402

Acceptability of selective reporting of antibiotic susceptibility testing results in primary care
Maïa Simon*, Gaelle Le Dref2, Sébastien Fougnot2, Patrice De Monchy2, Joëlle Kivits2, Céline Pulcini2, Nathalie Thilly2

1University De Lorraine, Nancy, France, 2University De Lorraine, Nancy, France

Background: Selective reporting of antibiotic susceptibility testing (AST) results is one possible antibiotic stewardship strategy. The ongoing “ANTIBIO-ciblés” pragmatic, prospective, multicenter, controlled, before-after study aims to assess the impact of selective reporting of AST for Escherichia coli positive urine cultures on the prescription of broad-spectrum antibiotics (co-amoxiclav, 3rd-generation cephalosporins and fluoroquinolones) by general practitioners (GPs) of a north-eastern region of France. Acceptability by GPs and laboratory professionals has been assessed to explore potential barriers to its implementation on a larger scale.

Methods: Twenty-one semi-structured individual interviews with a random sample of GPs and three semi-structured focus groups with laboratory professionals (biologists, technicians and secretaries) having respectively received and experienced selective reporting of AST were conducted to collect their perceptions about it. The main points discussed were their knowledge and their acceptability of the selective reporting of AST, the number and reasons of calls from primary care physicians (GPs and other specialties) to the laboratory to obtain the complete reporting of AST, and their perceptions of antibiotic resistance. Focus groups and interviews were transcribed to perform a comprehensive thematic analysis.

Results: Acceptability was high for all professionals, who considered selective reporting as an effective tool against antibiotic resistance. It was not perceived as an important constraint, neither by GPs nor laboratory staff. GPs found this tool helpful, and only complained about the time needed to obtain the complete reporting of AST in specific cases. These demands were however infrequent (1.3%). Laboratory professionals were therefore not over-solicited. Biologists expressed their desire to have more training, in order to better advise physicians when they called. According to them, making prescribers more aware of the threat of antibiotic resistance would further improve the effectiveness of selective reporting of AST. Selective reporting was also perceived positively by laboratory staff, as this highlighted their added value as antibiotic stewards.

Conclusions: Overall, selective reporting of AST was well accepted by both GPs and laboratory professionals. The results about impact of the “ANTIBIO-ciblés” study on antibiotic prescriptions will be available at the beginning of 2021.

7 Internal Medicine and Hepatology Unit, PO G. Da Procida-AOU- San Giovanni e Ruggi D’Aragona, University of Salerno, Naples, Italy
8 Internal Medicine, University of Campania L. Vanvitelli, Naples, Italy

Background: Despite the excellent efficacy, direct-acting antivirals (DAA)-regimens are associated with failure in about 5% of cases. To characterize the virological patterns and the resistant-associated substitutions (RASs) in the patients with failure to second-line DAA-regimen. It may help to identify the best approach of new line DAA-regimen

Methods: All the consecutive 63 HCV patients (pts) with failure to IFN-free regimen observed at the laboratory of infectious diseases of University of Campania, Naples from January 2018 to February 2019 were enrolled. All the pts had been treated with DAA-regimens according HCV genotype, international guidelines and local availability. Sanger sequencing of NS3 (for genotypes 1 and 4), NS5A and NS5B (for all genotypes) was performed at failure by home-made protocols.

Results: According to therapeutic outcome, 90.5% relapse, 4.7% breakthrough and 4.7% non-response. Among the 63 patients failed at three therapeutic regimens, 19 (30.1%) were treated with Sofosbuvir+Velpatasvir, 11 (17.4%) with Glecaprevir/Pibrentasvir and 33 (52.4%) with Elbasvir/Grazoprevir. The duration of DAA in months, median (range) 12 (8-24), the timing of resistance test in months at the end of treatment, median (range) 5 (1-19). The NS5A-RASs were more frequent in Sofosbuvir+Velpatasvir (17/19, 89.5%) and in Grazoprevir/Elbasvir (32/33, 97%) failed patients than in Glecaprevir/Pibrentasvir (4/11, 36.7%) failed patients (p=0.002 and 0.000 respectively). According to Sofosbuvir/Velpatasvir regimen 36.4% pts showed at least 2 RASs in at least two HCV region including NS5A and 70.3% pts showed at least 2 RASs only in NS5A region. Considering Grazoprevir/Elbasvir regimen 27.3% pts showed at least 2 RASs in at least two HCV region including NS5A and 88% pts showed at least 2 RASs only in NS5A region. (p=0.00). All 21 re-treated patients with Sofosbuvir/Velpatasvir/Voxilaprevir, obtained with SVR. The re-treatment was guided by genotyping test.

Conclusions: Patients with failure to a second-line therapeutic regimens frequently present mutation above all in the NS5A region. At re-treatment all patients obtained SVR. According to our real-life experience, re-treatment with the new regimes is effective and safe.

Improved diagnostic of acute gastrointestinal disease by a multiplex real-time PCR semi-automated method for the detection of enteropathogens

Berta Fidalgo*, Elisa Rubio García, Victor Pastor, Marta Parera, Cristian Aylagas, Pilar Salvador, Adán Fernández, Mariana José Fernández, Genoveva Cuesta Casco, Andrea Vergara, M. Eugenia Valls, Miriam José Alvarez Martinez, Maria Angeles Marcos, Clara Ballesté, Jordi Vila Estape, Miguel J. Martinez, Climent Casals-Pascual

1Hospital Clinic, Barcelona, Spain

Background: The identification of enteropathogens is critical for the clinical management of patients with acute gastrointestinal disease. New molecular methods have been developed to increase the diagnostic sensitivity. The aim of this study was to compare a multiplex real-time PCR analysis semi-automated platform (FLOW System®, Roche) that detects a combination of 11 enteropathogens (Table 1) with standard methods.

Materials/methods: A total of 10654 samples were analyzed. From 2013-2018 (July-September), stool samples were processed using standard microbiology methods: Culture for bacteria, microscopy for parasites and immunochromatography for viruses. In 2019, the FLOW system® was introduced.

Results: Study results are shown in Table 1. Other enteropathogens, like enteropathogenic E. coli, and parasites were not included in the table. The percentage of positive samples increased with the use of molecular methods. This trend was significant for bacterial pathogens ($P<0.001$) and G. intestinalis ($P=0.059$). Molecular methods identified 13 cases of G. intestinalis and 8 of Cryptosporidium spp unsuspected by clinicians. In 39 cases (3.62%), more than one enteropathogen was detected by FLOW.

Conclusions: FLOW system on stool samples improves diagnostic performance and is likely to modify routine microbiology protocols and clinical management. Molecular methods increase sensitivity, shorten turnaround time and may identify pathogens unsuspected by clinicians.

Abstract 4408

Identification of mutations in hepatitis B virus reverse transcriptase associated with a tenofovir-resistant phenotype in South African adults

Jolynne Mokaya*1, Tongai Gibson Maponga1, Marije Van Schalkwyk1, Susan Hugo2, Jantjie Taljaard2, Chikezie Nwankwo2, Joshua B Singer3, Mariateresa De Cesare1, David Bonsall1, Azim Ansari1, Wolfgang Preiser2, Monique Andersson1, Christo Van Rensburg2, Eleanor Barnes1, Anna McNaughton1, Philippa Matthews1

1University of Oxford, Oxford, United Kingdom, 2Stellenbosch University, Tygerberg, South Africa, 3Stellenbosch University, Tygerberg, South Africa, 4University of Glasgow, Glasgow, United Kingdom

Background: Tenofovir disoproxil fumarate (TDF) is widely recommended for treatment of chronic hepatitis B (HBV) infection because it has a high genetic barrier to resistance. TDF resistance associated mutations (RAMs) have been reported, but data are limited. We set out to identify RAMs in three individuals with detectable HBV viraemia on TDF treatment.

Materials/methods: We recruited adults with chronic HBV infection from Tygerberg Hospital, Cape Town, South Africa in 2018. Among 66 individuals with chronic HBV (17 HIV/HBV coinfected), 44 were on TDF, and three had persistent viraemia despite >12 months treatment. We sequenced HBV DNA for these three patients using MiSeq Illumina (whole genome target enrichment) and analysed for RAMs, applying maximum likelihood phylogenetic analysis to obtain genotypes.

Results: Consensus sequence from all three individuals contained RAMs that have been described in association with TDF resistance [Table], with at least 6 RAMs present in each. In participant 209, 12 putative TDF resistant mutations were present. Significant treatment non-adherence in this individual is unlikely as HIV-RNA was suppressed to a low level on TDF-containing antiretroviral therapy. RAMs Y9H and F122L/Y were present in all three individuals. All RAMs were present in >99% of HBV reads.

Conclusions: Our findings add to the evidence that RAMs in HBV RT can underpin a TDF resistant phenotype. This is the first time these RAMs have been reported from Africa in association with clinical TDF resistance. More data are required to determine the frequency and clinical impact of RAMs, to investigate the role of combination therapy, and to support development of new antiviral agents.

Table: Participants with persistent HBV viraemia on TDF.

Transcriptional and phenotypic responses to multidrug resistance plasmid acquisition are strain-specific in *Escherichia coli*

Steven Dunn*1, Laura Carrilero2, Mike Brockhurst2, Alan McNally1

1University of Birmingham, Birmingham, United Kingdom, 2The University of Sheffield, Sheffield, United Kingdom

**Background:** Multi-drug resistant (MDR) *Escherichia coli* are a global public health priority, and their incidence has been increasing since the start of the century. This is driven by a handful of successful MDR clones (e.g. ST-131). However, little is known regarding why some clones of *E. coli* are more able to acquire and maintain MDR plasmids. Data comparing the transcriptional and phenotypic responses of diverse *E. coli* strains to MDR plasmid acquisition are lacking.

**Materials/methods:** Using a combination of long and short read whole genome sequencing, as well as RNA-seq and phenotypic assays, several strains of *E. coli* were tested to determine their genomic and transcriptional response to novel MDR plasmid acquisition.

**Results:** Whilst very little genomic variation was detected across the dataset, the transcriptional landscape varied dramatically by strain. In general, there was a reduced transcriptional impact in MDR associated sequence types compared to environmental isolates. Genes that were differentially expressed in the dataset encompassed functions related to chemotaxis, flagellar, as well as carbohydrate, nitrogen, phosphonate and sulphur metabolism. These strains also varied by phenotype, displaying distinct effects to growth rates and conjugational efficiency.

**Conclusions:** The evolutionary cost of MDR plasmid acquisition is mitigated in a strain specific manner, with MDR associated clones displaying a reduced transcriptional impact. Further work is ongoing to characterise the effects of plasmid acquisition over long generational timeframes.

**Presenter email address:** s.j.dunn@bham.ac.uk
Risk factors for intra-abdominal candidiasis in intensive care units: results from EUCANDICU study

Matteo Bassetti1, Antonio Vena1*, Daniele Roberto Giacobbe1, Cecilia Trucchi2, Matteo Bassetti1, Antonio Vena1*, Daniele Roberto Giacobbe1, Cecilia Trucchi2,

Abstract 4414

Background: There are no studies specifically assessing risk factors for development of intra-abdominal candidiasis (IAC) among patients admitted to intensive care unit (ICU).

Materials/methods: We performed a case-control study in 26 ICUs from 10 European countries during the period January 2015- December 2016 [EUCANDICU project]. Patients ≥18 years-old who developed an episode of microbiologically documented IAC during their stay in the ICU (at least 48 hours after admission) served as the case cohort. The control group consisted of adult patients admitted in the ICU who did not develop episodes of invasive candidiasis during admission. Matching was performed at a ratio of 1:1 according to the exposition period (i.e. the period lasting between the admission in the same ICU ward of the case and the collection of the first positive sample for Candida).

Results: During the study period, we identified 101 case patients with a diagnosis of intra-abdominal candidiasis. The most commonly isolated species was C. albicans [58.4% of the isolates], followed by C. glabrata [15.8%] and C. tropicalis [4.0%]. Overall, resistance to fluconazole was detected in 17 out of 64 tested isolates (26.5%). At the univariate analysis of the comparison between patients with ICU-acquired IAC with those without an IAC, variables associated with IAC development included severe hepatic failure (7.9% vs 1.0%, p=0.03), receiving parenteral nutrition (64.4% vs 48.5%, p=0.03), re-intervention (84.9% vs 40.9%, p<0.001), recurrent gastrointestinal perforation (31.4% vs 6.8%, p=0.002), anastomotic leakage (45.3% vs 20.5%, p=0.007), previous antibiotic therapy (69.3% vs 41.6%, p=0.0001), higher median number of abdominal surgical interventions

Abstracts 2020

[3 vs 1, \( p=0.04 \)] and higher mean SAPS II score at the time of ICU admission (42 vs 34.6, \( p=0.007 \)). At multivariate analysis, risk factors independently associated with IAC were recurrent gastrointestinal perforation (OR 5.64; 95% CI 1.46-21.80, \( p=0.01 \)), anastomotic leakage (OR 2.86; 95% CI 1.11-7.38, \( p=0.03 \)) and receiving previous antimicrobial therapy (OR 2.91; 95% CI 1.24-6.80, \( p=0.01 \)).

Conclusions: Patients admitted to ICU have peculiar risk factors for IAC development. Prospective clinical studies are needed to identify which high-risk patients will benefit from antifungal prophylaxis.

**Abstract 4416**

**Triaging influenza in patients attending fever clinical scoring system for a modified influenza case definition**

Wu Liyuan*1, Jianyu Zhao1, Qianqian Zhou1, Xinxin Lu1

1Beijing Tongren Hospital, Beijing, China

**Background:** Reliable and rapid clinical predictors to assess the likelihood of influenza in the clinical practice are lacking. To develop such predictors, we undertook a prospective analysis of influenza in patients attending fever clinics.

**Materials/methods:** From 1 January 2019 to 28 March 2019, we analyzed the differences in clinical presentation and laboratory parameters between fever clinic patients with PCR-confirmed influenza infection (N = 461) and those with PCR-negative non-influenza infection (N = 204).

**Results:** In multivariate logistic regression analysis we identified four parameters, namely cough (OR 3.22, P = 0.000), sputum production (OR 1.70, P = 0.011), rhinorrhea (OR 1.73, P = 0.005) and lymphocyte counts (OR 0.313, P = 0.000), as independent predictors of influenza infection. A six point score, one point for sputum production, rhinorrhea, and two points for cough and lymphopenia (< 1.16x10^9/L) was calculated for influenza infection. The median score was significantly higher in influenza as compared to non-influenza (4 [IQR 3–5] vs 3 [IQR 2–4], P = 0.000). Receiver operating characteristics showed a moderately high diagnostic accuracy of this diagnostic score (AUC 0.74 [95%CI 0.70–0.77]), which was better as compared to each parameter alone. Of the 253 patients (38%) with a score > 4 points, 90% of patients had influenza infection, which was far superior to the influenza antigen test (89.7% vs 41.1%, P < 0.0001).

**Conclusions:** A simple and practical six point score based on cough, sputum production, rhinorrhea, lymphopenia can be used to stratify patients with influenza into different management groups.

Abstract 4424

Comparison of two commercially available qPCR kits for the detection of Candida auris
Anne Brunke1,2, Janko Sattler1,2, Georg Plum1, Pia Wiegel1, Oliver Kurzai3,4, Jacques F. Meis5,6, Axel Hamprecht1,2,7

1University of Cologne, University Hospital, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research, Partner Site Bonn-Cologne, Cologne, Germany, 3German National Reference Center for Invasive Fungal Infections, Leibniz Institute for Natural Product Research and Infection Biology - Hans Knöll Institute, Jena, Germany, 4University of Würzburg, Institute for Hygiene and Microbiology, Würzburg, Germany, 5Radboud University Nijmegen Medical Center, Department of Medical Microbiology, Nijmegen, Netherlands, 6Canisius Wilhelmina Hospital Nijmegen, Department of Medical Microbiology and Infectious Diseases, Nijmegen, Netherlands, 7University of Oldenburg, University Hospital, Institute of Microbiology and Immunology, Oldenburg, Germany

Background: Candida auris is an emerging fungal pathogen, which has been first described in 2009. Its emergence has become a major public health concern as this species shows resistance to several antifungals and has caused outbreaks on different continents. Identification of C. auris with standard microbiology techniques is prone to errors. So far detection of patients colonized with C. auris relies mostly on cultural methods. A quicker, molecular based detection of this pathogen could help to detect carriers of C. auris more rapidly and improve patient management. In this study, the performance of two commercially available qPCR kits for C. auris detection was assessed.

Materials/methods: The two kits Fungiplex Candida auris RUO Real-Time PCR (Bruker, Bremen, Germany) and AurisID (OLM, Newcastle Upon Tyne, GB) were challenged using genomic DNA of 29 molecularly characterized C. auris isolates belonging to five different clades. Additionally, three closely related Candida species (C. pseudohaemulonii, C. haemulonii and C. duobushaemulonii) were employed to determine specificity. Serial 10-fold dilutions of DNA starting with 60 ng genomic DNA/reaction were used to assess the qPCR kits. All PCRs were performed on an ABI 7500 Real Time PCR System.

Results: All tested C. auris strains were correctly identified by the AurisID kit in the undiluted samples and up to an amount of at least 6x10^-7 ng DNA. At 60 ng/reaction, all three non-C. auris strains gave rise to false positive results. The Fungiplex kit correctly identified the C. auris strains up to an amount of at least 6x10^-5 ng DNA; no false-positive results were recorded with this assay even at higher concentrations.

Figure 1: Detection limit of the two assays at different DNA loads.

Conclusions: Both kits show excellent analytical sensitivity and specificity at lower C. auris DNA concentrations which are expected in clinical specimen. AurisID demonstrated higher sensitivity but lower specificity. Both kits could help to rapidly detect C. auris in colonized patients, e.g. in case of an outbreak. However, future studies have to further evaluate their performance on clinical samples and their usefulness in the hospital setting.

Abstract 4426

Human mass balance study of enmetazobactam using 14C analysed by AMS
Paola Motta*, Stephen English1, Philip Barth1

1Allecra Therapeutics, Saint-Louis, France, 2Pharmaron, Germantown, United States

Background: Enmetazobactam (formerly known as AAI101) is a novel penicillanic acid sulfone β-lactamase inhibitor, active against a broad range of β-lactamases, including extended-spectrum β-lactamases (ESBLs) and some carbapenemases. Enmetazobactam (500 mg) is currently in Phase 3 clinical development in combination with cefepime (2 grams) for the treatment of adult patients with complicated urinary tract infections. We report here the results of a Phase 1 mass-balance study that investigated the disposition of enmetazobactam in healthy participants.

Materials/methods: Ten healthy adult males aged 27 to 58 received a single 2-hour IV infusion of 500 mg of enmetazobactam containing 1 µCi of enmetazobactam labeled with [14C]. Subjects remained in the clinical unit for 7 days after dosing for observation and collection of whole blood and excreta samples. Samples and HPLC fractions collected during metabolic profile analyses were analyzed for [14C] by accelerator mass spectrometry.

Results: Overall, approximately 99.7% of the administered 14C was recovered in the excreta (urine and feces combined) at the termination of the 168-hour collection period, with greater than 98% recovered in urine within the first 24 hours. Human plasma and urine samples collected in the first 24 hours after administration were analyzed and metabolite profiling successfully determined. Unchanged AAI101 represented 94.7% of the total radioactivity in plasma (as AUC pool) and 90% of the total radioactivity in urine. The remaining radioactivity was almost exclusively due to a single chemical entity (sulfinic acid product) that is intrinsically inactive and is formed by the cleavage of the AAI101 thiazolidine ring. The same chemical route has been observed during enmetazobactam degradation when the test item is stored above 25°C or during some extraction processes.

Conclusions: The recovery of a single dose of enmetazobactam was complete one week after dosing. Consistently with the results of the mass-balance studies conducted in human with other β-lactamase inhibitors (i.e., avibactam, tazobactam and vaborbactam), a great percentage of the administered radioactivity was found in urine, with the majority being recovered as unchanged drug in urine within the first 24 hours. The same disposition pattern was observed for cefepime, primarily excreted unchanged in the urine.

Abstract 4427

**Prevalence and clinical outcomes associated with viral and atypical bacterial co-infections in a large global study of adults hospitalised with influenza (INSIGHT FLU003 Plus)**

Dominic Dwyer1, Deborah Wentworth2, Norman Gerry3, Marie Hoover3, Jim Neaton2, Rick Davey4, Mark Polizzotto5, Tristan Clark6, Armando Paez7, José Ramón Paño Pardo8, Jens D. Lundgren9, Ab Babiker10, Sarah Pett11

1Sydney University and Westmead Hospital, NSWHP Westmead, Westmead, Australia, 2University of Minnesota, Minneapolis, United States, 3Advanced BioMedical Laboratories, Cinnaminson, United States, 4NIAID, Bethesda, United States, 5Kirby Institute, Sydney, Australia, 6Southampton General Hospital, Southampton, United Kingdom, 7Baystate Infectious Diseases Clinical Research, Springfield, United States, 8Hospital Clinico Universitario Losana Blesa, Zaragoza, Spain, 9CHIP, Department of Infectious Diseases, Rigshospitalet, Copenhagen, Denmark, 10MRC Clinical Trials Unit at UCL, London, United Kingdom, 11University College London, London, United Kingdom

Abstract third-party references: on behalf of the INSIGHT Study Group

**Background:** It is unclear how viral and atypical bacterial co-infections influence clinical progression among adults hospitalised with influenza.

**Materials/methods:** Adults hospitalised with influenza enrolled in FLU003 Plus were included. A Luminex NxTAG panel (includes influenza types/subtypes, respiratory syncytial viruses A/B, coronaviruses 229E/OC43/NL63/HKU1, human metapneumovirus, rhinovirus/enterovirus, adenovirus, parainfluenzaviruses 1/2/3/4, human bocavirus, atypical bacteria (C. pneumoniae/M. pneumoniae/L. pneumophila) was performed on the enrolment nasopharyngeal specimen. Seven days after enrolment, the patient’s clinical state was described using an ordinal outcome with six categories ordered by severity (death; ICU/intubated; hospitalised on oxygen or not; discharged and back to normal activities or not). Prevalence and determinants of any co-infection were assessed, the latter with logistic regression. A proportional odds model was used to compare those with/without co-infection for the 6-category ordinal outcome at Day 7. Unadjusted and adjusted (for age, in ICU or on oxygen in the general ward at enrolment, geographic region, influenza type), proportional odds ratios (ORs), 95% CIs and 2-sided p-values are cited. Other baseline factors were included in the adjusted model if associated with co-infection. ORs by influenza type were compared by including an interaction term in the ordinal regression model.

**Results:** Among 1947 patients with Luminex-panel confirmed influenza (median age 61 years, 52% female, median five days since symptoms onset), 92 (4.7%) had a viral co-infection; 2/92 patients also had an atypical bacterium infection. Most patients (91%) had only one co-infection. Longer duration of symptoms at enrolment (p=0.02) and being immunocompromised (p<0.001) were associated with an increased co-infection prevalence. Co-infection was associated with a less favourable outcome category at day 7 (OR=0.66, 95%CI:0.45-0.98, p=0.04). After adjustment, the OR was 0.78, 95%CI:0.52-1.17, p=0.23. ORs of a favourable outcome with co-infection did not vary by influenza A/B type (p=0.87).

**Conclusions:** The prevalence of viral co-infections in hospitalised laboratory-confirmed influenza in a global study was low. Atypical bacterial co-infections were uncommon. After adjustment, the presence of co-infections considered did not significantly affect 7-day clinical status. The clinical benefit of testing for other viral pathogens in laboratory-confirmed influenza may be limited.

**Abstract 4434**

**Dissemination of carbapenem-non-susceptible Klebsiella pneumoniae from Oman**
Maarten Coorens1,2, Hissa Al Farsi*1,3, Isak Sylvén1,4, Zakariya Al-Muharrmi5, Saleh Al-Azri3, Amina Al Jardani3, Christian Giske1,2

1Karolinska Institute, Stockholm, Sweden, 2Karolinska Institute Hospital, Stockholm, Sweden, 3Central Public Health Lab, Muscat, Oman, 4Science For Life Laboratory, Stockholm, Sweden, 5Sultan Qaboos University Hospital, Muscat, Oman

**Background:** Carbapenem-resistant Klebsiella pneumoniae (CR-Kp) is considered one of the major challenges in the fight against antimicrobial resistance. While certain clonal groups, such as CG258, are currently the major cause of CR-Kp infections, new successful high-risk clones can emerge rapidly. As the prevalence of CR-Kp has not been thoroughly investigated in the Middle East, including Oman, this study aimed to identify and characterize CR-Kp in Oman.

**Materials/methods:** Two hundred and thirty-seven suspected CR-Kp isolates were collected between January-November 2015 from 11 different hospitals throughout Oman. They were examined phenotypically with disk diffusion and interpreted using EUCAST guidelines. Next, DNA extraction and Illumina-NGS were performed. Genomes were assembled using Unicycler. Resistance mechanisms were identified using the CARD database, while sequence types, species, as well as virulence factor presence were determined using Kleborate. BIGSdb database was used to assign new STs when required. SNP-based analysis was performed to determine genetic variation and classical Multidimensional Scaling (CMD-scaling) was used to plot genetic diversity within different STs.

**Results:** The majority of isolates were K. pneumoniae strictu sensu, while 2 strains were K. quasipneumoniae. Carbapenem-resistance was mostly caused by OXA-48-like enzymes (n = 86), in particular OXA-232, followed by NDM-1 enzymes (n=81). Interestingly, 18 strains co-produced NDM-1 and OXA-48-like enzymes. The most common STs identified were ST231 (32%) and ST11 (32%), followed by ST147 (15%) and ST15 (7%). Interestingly, low clonal diversity was observed within ST231 isolates compared to the other ST groups. Furthermore, an association between ST and carbapenemase genes was observed, with NDM-1 being completely absent in ST231 isolates, while most ST231 isolates expressed the OXA-232 carbapenemase. Finally, a high percentage of ST231 isolates (80%) express both aerobactin and yersiniabactin virulence genes, which could be an important contributor to its effective national dissemination.

**Conclusions:** This study showed that expression of OXA-232 and NDM-1 are the leading causes of carbapenem-resistance among K. pneumoniae in Oman. In addition, our results identified a ST231 clone co-expressing both OXA-232 as well as aerobactin and yersiniabactin virulence factors, which could be indicative of the emergence of a high-risk hypervirulent multi-drug resistant clone.

Elucidating the role of the essential operon yajC-secD-secF in Burkholderia spp.; a possible new target for new antimicrobial molecules

Elena Perrin*1, Marco Fonai1, Renato Fani1, Alessio Mengoni1

1Department of Biology, University of Florence, Sesto Fiorentino, Italy

Background: Infections caused by species belonging to the *Burkholderia cepacia* complex (Bcc) have a high mortality rate among immunocompromised and Cystic Fibrosis (CF) patients, due to the high levels of intrinsic antibiotic resistance of these bacteria. Consequently, the search of new therapeutic approaches to fight Bcc infections is crucial for these patient categories. Our aim is to understand the role of SecDF proteins in Bcc species in order to evaluate the possible use of this system as a new antibiotic target.

SecDF proteins, included in the Resistance Nodulation Cell-Division Superfamily (RND) of efflux pumps, are present both in Bacteria and Archaea. Some roles have been suggested for this system in different microorganisms (from protein translocation across or into the inner membrane of prokaryotes to antibiotic resistance) but its function in bacterial cells remains elusive and, although this efflux system proved to be non-essential for cells viability in all the microorganisms in which it has been studied to date, recently, the use of the "transposon mutagenesis with next-generation sequencing", TnSeq technology, revealed that the genes coding for these two proteins are essential in a variety of different microorganisms.

Materials/methods: We developed a strategy to understand the role of SecDF, based on a multiomic characterization (transcriptomics, metabolomics and phenotypic characterization) of a SecDF conditional growth mutant.

Results: A SecDF conditional growth mutant has been obtained and a preliminary characterization of its growth has been performed. A microscope observation of the cells showed problems of cell division. All the other experiments are in progress.

Conclusions: The understanding of the exact role that SecDF proteins have in bacterial cell is crucial to evaluate the role for this system as possible target for the design of new antimicrobial molecules, directed against all the microorganisms in which this system is essential, as Bcc species.

Abstract 4437

**High utility of Gram-stain of urine specimens for guiding empiric clinical management of pyelonephritis**

Koji Oh*1, Kazusa Egami2, Chihiro Nishio1, Hironobu Goshima1, Hiroki Konishi1

1Kobe City Medical Center West Hospital, General Internal Medicine, Kobe, Japan, 2Kobe City Medical Center West Hospital, Department of Microbiology, Kobe, Japan

**Background:** Gram-stain is a simple and still useful method for guiding empirical clinical management without expensive equipment. Interpretation of urine gram-stain is generally easier than that of other kinds of specimens like sputums. The current guidelines for pyelonephritis recommend starting treatment with antibiotics against gram-negative bacilli (GNB) such as *Escherichia coli*, although gram-positive cocci (GPC) are occasionally responsible. Previous studies have not reported specified conditions that require empirical antibiotic coverage against gram-positive organisms. The guidelines do not mention the utility of gram-stain of urine specimens.

**Materials/methods:** A single-center, retrospective study at a 358-bed community teaching hospital in Japan. Medical records were reviewed for adult inpatients diagnosed as pyelonephritis with positive blood cultures between 2016 and 2019. We evaluated the results of gram-stain of urine specimens, the results of urine and blood cultures, the proportion of causative organisms, the options of antibiotics as empirical therapy, and their clinical courses.

**Results:** We extracted 217 cases of pyelonephritis (mean age 78.1 years, male 30.0%). GPC proved responsible in 18 of the 217 cases (8.3%, 95%CI: 5.0-12.8%). They were streptococci in 8 cases, staphylococci in 5 cases, enterococci in 4 cases, and *Aerococcus spp.* in 4 cases, including the cases in which multiple organisms were responsible, specifically. Cefmetazole had been chosen most frequently as empirical therapy (67.3%). During empirical therapy, the GPC cases tended to receive inappropriate antibiotics compared with the GNB cases (27.8% vs. 2.5%, p<0.001). The empirical antibiotic therapies based on the results of gram-stain contributed to the adequate coverage of causative organisms (p=0.017). Regarding the interpretation of the urine gram-stain results, the proportion of GPC as causative organisms was very high when GPC were observed without GNB (97.8%), conversely, the proportion was low when GPC were observed with GNB (9.3%, p<0.001). Cox regression analysis identified independent predictors for pyelonephritis with GPC: male sex (p=0.016) and renal-ureteral stones (p=0.046).

**Conclusions:** Empirical therapies tend to be inappropriate in pyelonephritis cases caused by GPC. Gram-stain of urine specimens could lead to better decisions for adequate antibiotic regimens during empirical therapy. The guidelines should mention the potential of gram-stain.

Abstract 4440

Comparison between visual reading, smartphone image and digital scanner interpretation of lateral flow device result for detecting Aspergillus-specific IgG

Bayu Wilopo*1,2, Elizabeth Hunter1, Phil Goodwin3, Elliott Phillips3, Gareth Platt1, Malcolm Richardson1,4, David W. Denning1,5

1Division of Infection, Immunity and Respiratory Medicine, The University of Manchester, Manchester, United Kingdom, 2Division of Microbiology, Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia, 3Bio-Check (UK), St. Asaph, United Kingdom, 4Mycology Reference Centre, Excellence Center for Medical Mycology (ECMM), Wythenshawe Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom, 5National Aspergillosis Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: Chronic pulmonary aspergillosis (CPA) is a fungal disease with an estimated 3 million cases worldwide, and most patients are from low-middle income countries (LMIC) with limited access to diagnostic tests. A lateral flow device (LFD) is an inexpensive device that can identify an analyte in a clinical sample effortlessly. We tested an LFD prototype that is being developed for detecting Aspergillus-specific IgG using recombinant antigens and interpreted the results using three different methods: a visual reading, a smartphone image and a digital scanner.

Materials/methods: Sera from 122 CPA patient and 123 healthy controls were used for this study. All readers were blinded to the patient diagnosis at the time of interpretation. Visual reading interpretation was done by one reader immediately following incubation. After that, the device was scanned using a Qiagen ESEQuant LR3 (Lake Constance, Germany) lateral flow reader and finally, a smartphone image was taken. Smartphone image interpretation was done by three readers at different times, a third reader adjudicated if there was a difference between the interpretation of first and second readers. Sensitivity and specificity of each interpretation were recorded.

Results: Visual interpretation sensitivity and specificity were 75.4% (95% CI [66.8-82.8%]) and 63.4% (95% CI [53.4-71.9%]), respectively. Smartphone image interpretation sensitivity and specificity were 62.3% (95% CI [53.1-70.9%]) and 74.0% (95% CI [65.3-81.5%]), respectively. Optimum cut-off for the digital scanner was 41.7 mV. At this cut-off, the sensitivity and specificity for the digital scanner were 76.2% (95% CI [67.7-83.5%]) and 60.2% (95% CI [51.0-68.9%]), respectively.

Conclusions: Based on these results, the digital scanner interpretation and visual interpretation provided the highest sensitivity, followed by the smartphone image. Although the smartphone image interpretation had the lowest sensitivity, it is still suitable for recording LFD results in LMIC settings. Research to develop applications or platforms for digital reading that can be integrated with a smartphone will be very important, as developments of LFD as diagnostic tools is progressing rapidly.

Abstract 4441

Resistance trends among the common bacterial causes of community-acquired lower respiratory tract infection in the UK and Ireland, 2008-2018

Carolyne Horner, Shazad Mushtaq, David Livermore

1Birmingham, British Society for Antimicrobial Chemotherapy, Birmingham, United Kingdom, 2London, Public Health England, London, United Kingdom, 3Norwich, University of East Anglia, Norwich, United Kingdom

Abstract third-party references: The British Society for Antimicrobial Chemotherapy Standing Committee on Resistance Surveillance

Background: The BSAC Respiratory Resistance Surveillance Programme has monitored antimicrobial susceptibility of Haemophilus influenzae, Moraxella catarrhalis and Streptococcus pneumoniae from community-onset lower respiratory tract infections (CO-LRTI) in the UK and Ireland since 1999/2000. We review data for 10 surveillance seasons (Oct 2008 – Sept 2018).

Materials/methods: Consecutive isolates causing CO-LRTI were tested; participating laboratories (n=21-39) collected 14-20 isolates of H. influenzae and S. pneumoniae, and 7-10 isolates of M. catarrhalis per season. MICs were determined centrally by BSAC agar dilution. Isolates of S. pneumoniae were serotyped from Oct 2013.

Results: Among H. influenzae (n=4738), 959 (20%) produced β-lactamase. Rates of resistance to aminopenicillins and amoxicillin-clavulanate increased (amoxicillin: 19% 2008/09 – 31% 2017/18; ampicillin: 20% 2008/09 – 30% 2014/15; amoxicillin-clavulanate: 0.4% 2008/09 – 9.1% 2017/18); whereas resistance to cefotaxime remained low (mean 0.7%). Rates of resistance to ciprofloxacin, erythromycin, and tetracycline were ≤2% without trend; 27/845 (3%) H. influenzae were resistant to ceftaroline. Cefotiboprole MICs ranged from 0.004-2mg/L (median 0.06mg/L). Among M. catarrhalis (n=2266), 2188 (92%) produced β-lactamase. All isolates tested were susceptible to amoxicillin-clavulanate, cefotaxime and erythromycin. Resistances to ciprofloxacin (n=8), cefuroxime (n=4), and tetracycline (n=2) were rare. MICs of ceftaroline ranged from 0.002->4mg/L (median 2mg/L; n=38, MIC >4mg/L) and ceftobiprole from 0.008->4mg/L (median 1mg/L; n=9, MIC >4mg/L); four isolates had a MIC >4mg/L to both agents. Four S. pneumoniae isolates (n=3921) were resistant to penicillin (MIC 4-8mg/L), whilst MICs for 485 (12%) were from 0.12 – 2 mg/L (no trend). Increasing resistance was seen for tetracycline (9% 2008/09 – 14% 2017/18) and clindamycin (4% 2008/09 – 11% 2017/18); whereas resistance to erythromycin remained stable (mean 1%). Resistances to ceftaroline (1/670) and ceftobiprole (13/2416) were rare. Serotyping was completed for isolates ≥3 years into the PCV13 era; 78 serotypes were represented, most commonly 15A (8.7%), 11A (8.1%), and 23B (5.3%). There were 312 (12%) isolates with a serotype within PCV13, most commonly 3 (43%), 19F (28%) and 19A (19%).

Conclusions: M. catarrhalis remain largely susceptible to existing antimicrobials; however, an increase in the rate of resistance to first line β-lactams was identified in H. influenzae. For S. pneumoniae the rise of often-multiresistant serotype 15A is a concern.

Abstract 4444

**Epidemiology of cardiac surgical site infection in England, 2018/19**
Theresa Lamagni*1, Kristine Cooper1, Catherine Wloch1, Pauline Harrington1

1Public Health England, London, United Kingdom

**Background:** Data collected by hospitals participating in national surgical site infection (SSI) surveillance provide an invaluable tool to assess local changes in risk and national trends. We extracted data on cardiac procedures from NHS hospitals participating in the Public Health England national surveillance programme to update our understanding of current epidemiology.

**Methods:** Hospitals participating in voluntary surveillance of coronary artery bypass graft (CABG) and other cardiac non-CABG procedures (primarily valve repair/replacement) prospectively followed-up patients to detect infection (based on ECDC/CDC definitions) up to 1y after surgery. Infections were detected during the inpatient stay or on readmission. Optional patient post-discharge questionnaires (PDQ) were utilised by hospitals; patients self-completed PDQs 30d after surgery with possible signs of infection reviewed by hospital staff. Operations from 2018/19 were analysed, with sub-analysis for hospitals achieving >70% PDQ return rate.

**Results:** During 2018/19, 16 hospitals participated in cardiac surveillance submitting 9,866 procedures, 5,994 CABG and 3,872 cardiac (non-CABG). The latter included 293 paediatric procedures (<18y), 136 on infants. Inpatient and readmission-detected SSI risk was 2.27% for CABG, 1.79% with exclusion of donor incisional site SSIs. For cardiac (non-CABG), SSI risk was 1.32% overall and 2.05% in children. Most CABG SSIs were superficial infections (64%), with 28% deep incisional and 8% organ/space; equivalent breakdowns for cardiac (non-CABG) were 37%, 45% and 18%. Enterobacteriaceae were the most common causative pathogens [41.8% CABG SSI, 33.3% non-CABG]. Median time to infection (all detection methods; Figure) was 16d for CABG and 18d for cardiac (non-CABG). Inclusion of PDQ-detected SSIs increased SSI risk from 2.53% to 8.55% (IQR 6.99-11.20%) for CABG and 1.04% to 2.19% (IQR 1.04-2.40%) for cardiac (non-CABG) in 5 hospitals using this methodology. One in 200 cardiac (non-CABG) patients was readmitted for management of SSI, rising to 1 in 75 for CABG.

**Conclusions:** Surveillance data provide a valuable platform to understand the epidemiology of cardiac SSI, informing the design of local and national interventions and providing a means to assess their impact.

Figure: Onset of surgical site infection (inpatient and post-discharge detected) following coronary artery bypass graft (CABG) and cardiac (non-CABG) surgery, England 2018/19

Quantitative detection and impact of 5’ terminally deleted Group B enterovirus populations on type I IFN response in peripheral blood or heart tissue samples from acute myocarditis pediatric patients

Marie Glenet, Yohan Nguyen, Audrey Mirand, Cécile Henquell, Anne-Laure Lebreil, Fatma Berri, Firouze Bani Sadr, Bruno Lina, Isabelle Schuffenecker, Laurent Andreoletti

1Faculty of Medicine and Pharmacy of Reims Champagne-Ardenne, EA4684 Cardiovir Virology research laboratory, Reims, France, 2Hospital Robert Debré, Reims, France, 3Clermont Auvergne University, Clermont-Ferrand, France, 4Centre Hospitalier Universitaire, Clermont-Ferrand, France, 5National Reference Center of Enterovirus and Parechovirus, Clermont-Ferrand, France, 6Faculty of Medicine and Pharmacy, EA 4684 CardioVir, Reims, France, 7Hospices Civils De Lyon - Hcl, Lyon, France, 8Université de Lyon, Lyon, France, 9National Reference Center of Enterovirus and Parechovirus, Lyon, France

Background: Group B enteroviruses (EV-B) are common causes of acute myocarditis, which can be a precursor of chronic myocarditis and dilated cardiomyopathy (DCM), leading causes of heart transplantation. Major enterovirus B populations characterized by 5’ terminal genomic RNA deletions ranging up to 50 nucleotides (5’T-D) were identified either alone or associated with low proportions of intact 5’ genomic termini (FL) in heart tissue biopsies from acute myocarditis and chronic dilated cardiomyopathy (DCM) patients [1]. Dynamics of emergence of EVB-TD populations from the acute myocarditis to chronic DCM stage remain unknown.

Materials/methods: In the present study, we used an original rapid amplification of cDNA ends (RACE) PCR assay followed by micro-electrophoresis allowing quantifying FL or 5’T-D EV-B RNA genomes in clinical samples. Using this valuable molecular approach, we analyzed seven plasma and four heart tissues samples [French Enterovirus reference centers: 2015-2017] taken from seven pediatric acute myocarditis patients.

Results: EV-B viral load levels were assessed by a specific RT-qPCR assay in peripheral blood samples [5.0×10^4 cp/mL [1.82×10^3-2.98×10^4] and heart samples [4.50×10^6 cp/µg [3.97×10^4 – 9.85×10^6] of acute myocarditis cases. Our results evidenced the detection of STD RNA genomes ranging from 37 to 50 nucleotides (90 %) associated to FL (3 %) or 5’T-D RNA genomes ranging from 8 to 36 nucleotides (7 %) in the early stage of acute myocarditis. In study samples, IFN-β mRNA levels appeared to be negatively correlated with proportions of 5’T-D RNA genomes ranging from 37 to 50 nucleotides [R^2=0.811, P=0.006] whereas a positive correlation was observed between IFN-β mRNA levels and proportions of minor 5’T-D 8-36nt forms [R^2=0.905, P=0.001]. Following transfection of EVB-TD and FL forms in human cardiomyocytes (HCM), IFN-β mRNA and cytokine levels appeared to be significantly higher for the FL and minor 5’T-D 8-36 nt forms comparatively to 5’T-D 37-50 nt forms [P=0.0087].

Conclusions: In conclusion, our RACE PCR assay allowed the identification of major 5’terminally deleted EV-B populations in peripheral blood and cardiac tissues of acute myocarditis patients. Moreover, the proportions of minor 8 to 36nt EVB-TD and FL populations could modulate the innate immune sensing mechanisms in human cardiomyocytes.

Abstract third-party references: On behalf of the DZIF R-Net study group

Background: The increase of vancomycin resistance among Enterococcus faecium in Europe is alarming (from 10.5% to 17.3% between 2015 and 2018, ECDC). We aimed to identify the VRE prevalence upon hospital admission and to analyze risk factors for VRE colonization.

Materials/methods: From 2014 to 2018 patients were recruited within 72h of admission to seven participating German university hospitals. Screening for VRE was performed and data on potential risk factors (prior MDRO detection, current and prior antibiotic consumption, prior hospital, rehabilitation or long term care facility stay (LTCF), international travel, animal contact, and consumption of medication for gastro oesophageal reflux disease) were collected by structured interviews. VRE were detected on ChromID® VRE plates (biomerieux), phenotypical resistance was further tested by means of Vitek®2 (biomerieux) and genotypical analysis was performed by cgMLST analysis (Ridom SeqSphere+). Multivariable analysis was performed for VRE colonization and specific sequence types (ST).

Results: In five years, 17351 patients were recruited. The median age was 62 years (IQR 50-73) and 8198 were women (47.2%). In total, 270 patients were colonized with VRE on hospital admission – a prevalence of 1.6%. Risk factors for VRE colonization were antibiotic treatment at the time of screening (aOR 3.62; 95% CI 3.39-3.86), prior MDRO detection (aOR 3.19, 95%CI 2.59-3.93), stay in a LTCF (aOR 2.31, 95% CI 1.74-3.06), stay in a German hospital (aOR 3.33, 95%CI 2.41-4.60) and consumption of PPI or antacids (aOR 1.38, 95% CI 1.25-1.53). The VRE admission prevalence increased by 29% per year. cgMLST showed that 137 (50.7%) of the VRE were ST117, with a steep increase over the years (Table 1). Multivariable analysis revealed that ST117 and non-ST117 VRE differed only with respect to the admission year.

Conclusions: As vancomycin resistance rates increase, so does the VRE admission prevalence, mainly driven by the emergence of ST117. Different health care contacts seem to put patients at risk for VRE colonization.

Abstract 4451

Microbiota as a marker of mucoid Pseudomonas aeruginosa and Haemophilus influenzae in non-cystic fibrosis bronchiectasis

Ruben López1, Laia Fernandez Barat*,1, Nil Vazquez1, Victoria Alcaraz1, Leticia Bueno1, Roberto Cabrera1, Giulia Scioscia2, Patricia Elena Oscanoa1, Rosanel Amaro1, Antoni Torres1

1Pneumology Department, Hospital Clínic, Barcelona, Spain, Cellex laboratory, CibeRes (Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, 06/06/0028)- Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), School of Medicine, University of Barcelona, Spain, Barcelona, Spain; 2Foggia, Pneumology Department, Hospital Clínic, Barcelona, Spain, Foggia, Italy

Background: Pseudomonas aeruginosa (PA) and Haemophilus influenzae (HI) are two of the main pathogens in non-cystic fibrosis bronchiectasis (BE) chronic colonization. However, scarce evidence exists on respiratory concomitant microbiota patterns associated to each of the two pathogens, in particular when mucoid PA is present. The purpose was to determine if Pseudomonas aeruginosa (PA) non-mucoid (group 1) or mucoid (group 2), Haemophilus influenzae (HI) (group 3), and combined presence of mucoid PA and HI (group 4) are associated to any particular pattern of concomitant microbiota also clustering by BE alone or plus Chronic obstructive pulmonary disease (BE-COPD).

Materials/methods: Sputum in BE patients with at least 1 previous PA isolation was collected prospectively. Sputum samples were isolated by Norgen DNA sputum kit. The preparation of the DNA libraries was based on the hypervariable regions V1, V2, V3, V4, V5, V6, V7, V8 and V9 regions for bacterial 16S rRNA. DNA libraries were created and purified using the QIASeq Screening Panel 16S/ITS and Agencourt AMPure XP Beads. The pool of DNA libraries was introduced into Illumina Miseq platform. The bioinformatic analyses were performed by QIIME and Mothur with GreenGenes microbiome database, the pipeline design was adjusted for our objectives.

Results: Twenty-nine sputa were included in the analysis by groups 1 to 4 (n=5, n=9; n= 5 and n=10, respectively). Twenty-seven taxonomic units were found. PA and HI were present in all groups having the highest abundance of PA or HI the group 4 (p=0.022) or group 3 (0.007), respectively. HI was higher in the BE-COPD group compared to BE alone (520.5[207.5-11629.3] vs 49.5[0.0- 175.0], p=0.007, respectively).

Interestingly, four study groups differed in terms of concomitant microbiota. For instance, Carnobacteriaceae were only found in group 1 but Leptotrichiaceae, Fusobacteriaceae, Porphyromonadaceae, Erysipelotrichiaceae and Paraprevotellaceae were only found in group 2, being the fusobacteriaceae the ones with higher abundance. Mycoplasmataceae, Gemellaceae and Pectostreptococcaceae were only found in group 4 being the Gemellaceae the ones with higher abundance.

Conclusions: The use of Fusobacteriaceae or Gemellaceae as markers of mucoid PA or mucoid PA with HI colonization needs further investigation but could impact in clinical management of BE patients.

Abstract 4453

An outbreak of Clostridioides difficile infections due to a 027-like PCR ribotype 181

Melina Kachrimanidou1*, Amoe Baktash2, Despoina Dimoglou1, Fotini Netsika4, Olga Tsachouridou1, Dimitra Papadopoulou4, Efthymia Protonotariou1, Lemonia Skoura4, Metallidis Symeon4, Ed J. Kuijper2

1Medical School, Aristotle University Thessaloniki, Greece, Thessaloniki, Greece, 2Leiden University Medical Center, Leiden, Netherlands, 3Medical School, Thessaloniki, Greece, 4Ahepa University Hospital, Thessaloniki, Greece

Background: Clostridioides difficile is one of the most important healthcare-associated pathogens in Europe. Recently, a number of 027-like so-called “hypervirulent” types have been found that all belong to the Clade II, but have an unknown clinical and epidemiological presentation.

Materials/methods: We identified a rapidly spreading outbreak of nineteen episodes of C. difficile infections (CDI) in a Greek 180-bed Rehabilitation Clinic (RC) within a 28-day time-period (29 March to 25 April 2019). C. difficile PCR Ribotype (RT) 027 was presumed since a diagnostic PCR revealed the presence of a typical frame shift mutation at position 117 of TcdC. Using the ESCMID definitions, the outbreak was associated with mild to moderate disease and 6% of the patients developed a relapse. Cultured strains showed an unknown RT 027-like type and were sent to Leiden University Medical Centre for further characterization. Core genome multilocus sequence typing (cgMLST) was performed in Seqsphere and the sequence data were used to build a neighbor joining tree.

Results: The CDI incidence rate on the RC was 49 infections per 10,000 patient days (29 March-25 April 2019), which nearly quadrupled compared to previous infection rates. Of 19 cultured isolates, 15 displayed the same RT 181 profile. All clinical RT 181 isolates from Greece belonged to (MLST) ST1 and were positive for tcdA, tcdB and the binary toxin genes and also had a 18bp deletion in tcdC at position 311 together with a single nucleotide deletion at position 117, similarly to RT 027. The RT 181 Greek strains clustered with two RT181 reference strains (kindly provided by University of Leeds). The RT 181 outbreak isolates were closely related to each other, belonged to MLST Clade 2, but differed around 10% in their core genome allelic profiles from the rest of Clade 2. [Figure 1] The outbreak strain was resistant to fluoroquinolones and macrolides, but susceptible to vancomycin and metronidazole.

Conclusions: New C. difficile ribotypes still emerge at unexpected time and location without a clear source. C. difficile RT 181 was rapidly spreading but not associated with increased mortality and higher relapse rates.
**Figure 1.** Neighbor-joining tree of strains from Greece (n=18) and control samples (n=7) from other RTs. RT181 (CD181-01 – CD181-15) and RT036 (CD036-01, CD036-02) strains from Greece belong to Clade 2 (yellow). Strain with unknown *ribotype* from Greece is coded with CD999-01 and belongs to Clade 1. RTs 001, 027, 023, 017 and 078 from Clade 1, 2, 3, 4 and 5 are colored red, yellow, green, blue and purple, respectively. The distance is given as a fraction of allelic differences.

Diversity of beta-lactamase genes carried by multidrug-resistant Enterobacteriaceae clinical isolates in Georgia

Nabil H. Latif1, Tinatin Aptsiauri1, Maia Nozadze1, Nino Butskhrikidze2, Tamar Didbaridze1, Paata Imnadze4, Michael Washington1, Shannon D. Walls1, Nino Trapaidze*1

1US Army Medical Research Directorate – Georgia (USAMRD-G), Tbilisi, Georgia, 2Evex Medical Corporation, Tbilisi, Georgia, 3The First University Clinic of the Tbilisi State Medical University, Tbilisi, Georgia, 4The National Center for Disease Control and Public Health of Georgia, Tbilisi, Georgia

Background: The prevalence of the beta-lactam resistant enterobacteriaceae, specifically the 3rd generation cephalosporins and carbapenems, is steadily increasing and spreading globally. Antibiotic resistance is supported by various molecular mechanisms, including intrinsic and acquired resistance genes. Here, we examined an antibiotic resistance phenotype and beta-lactam gene content of MDR clinical isolates of enterobacteriaceae and Pseudomonas aeruginosa, recovered from patients at intensive care units of multi-profile hospitals in the Country of Georgia.

Materials/methods: Bacterial isolates were collected between July 2017 and May 2019 from four clinical sites in Georgia. Bacterial identity and antimicrobial susceptibility were determined by the Vitek 2 automated system according to CLSI standards. Antimicrobial resistance gene content was examined by multiplex PCR (Streck Inc.), targeting plasmid-mediated AmpC and beta-lactamases, representing fifteen gene families.

Results: 168 specimens, consisting of Klebsiella pneumoniae (n=72), Escherichia coli (n=51), Serratia marcescens (n=10) and Pseudomonas aeruginosa (n=35) were selected for this study. It was found that 100%, 97%, 94% and 78% of S. marcescens, P. aeruginosa, K. pneumonia and E. coli isolates, respectively, were multi-drug (MDR) resistant. CTX-M-15 or CTX-M-14 extended spectrum beta-lactamase genes were detected in 100% of MDR K. pneumonia and E. coli strains, followed by 78% and 13% found among MDR S. marcescens and P. aeruginosa. In addition to CTX-M-15 gene, subset of K. pneumonia co-harbor OXA-48 (n=15) or NDM (n=8) carbapenem resistance genes, whereas single E. coli isolates were found to also carry OXA-48 (n=1), NDM (n=1), VIM (n=2) and IMP (n=2) carbapenem resistance genes. In addition, only two strains of S. marcescens demonstrated the presence of OXA-48. VIM and IMP were found in 11 and 2 strains of P. aeruginosa, respectively. DHA and EBC were co-harborred together by one isolate of E. coli, and CMY-2 was found in single isolate. MOX ACC and FOX genes were not detected in any of presented isolates.

Conclusions: Multi-drug resistance has been observed in bacterial isolates recovered in the country of Georgia. Detection of highly transmissible plasmid associated resistance genes indicates the high potential for horizontal spread of resistance that in combination with already existing multi-drug resistance could lead to the emergence of a novel “superbug” in Georgia.

Hospital onset bloodstream infection (HOBSI) as a marker of the burden of hospital associated infection (HAI) in a tertiary care hospital in South India

Ranganathan N. Iyer*1, Rekha Jangam2

1Global Hospital, Hyderabad, India, 2Global Hospital, Hyderabad, India

Background: CLABSI, though accepted, may not be a reliable marker of the burden of HAI. Hospital onset Bloodstream infection (HOBSI) is proposed to be a better indicator of the burden of HAI in a hospital. This study is an attempt at comparing HOBSI with CLABSI as a marker to determine the burden of HAI in minimal resource countries.

Materials/methods: A retrospective analysis of patient records, blood culture data and summaries with blood stream infection was carried out from 2017-2018 to determine the number of HOBSI episodes in patients admitted to the hospital. This was compared with the CLABSI rates defined for the two years of study. Standard definitions were used for HOBSI- BSI first identified on blood culture drawn >48 hours after hospital admission or within 48 hours following hospital discharge and CLABSI as per CDC NHSN criteria. An attempt was made to identify the source for HOBSI along with the core organisms causing infections.

Results: A total of 54 HOBSI episodes (0.8/1000 Patient days) were found in the two years of which 37 were detected in 2017 (1.14/1000 patient days) and 17 in 2018 (0.51/1000 patient days). The chief sources for HOBSI were urinary tract (33.3%), those related to surgical complications and procedures (25.9%), complicated stent with PTBD procedures (18.5%), lower respiratory tract infections including VAP (11.1%), CLABSI (9.25%) and dialysis catheter induced BSI in 3 (5.5%). The core organisms were found to be Klebsiella pneumonia 19 of which 14 were carbapenem resistant (CRE), E.coli 16 of which 7 were CRE, and Enterococcus faecalis in 7 episodes. The corresponding documented CLABSI rates were 4 (0.91/1000 CLT days) and 2 (0.2/1000 CLT days) in 2017 and 2018 respectively.

Conclusions: HOBSI is a better and reliable indicator of the HAI burden in a hospital in comparison to CLABSI. Episodes of BSI not attributed to CLABSI but adding to the overall burden of HAI could be determined using this indicator. A retrospective HOBSI analysis of patient data was possible which is not possible with CLABSI.

Abstract 4458

**qPCR inhibitors/enhancers: the interference in the reaction by drugs used for patient treatment or ingested by the patients**

Eva Machetti-Mareca1,2, Raquel Morales Hernández2, Cristina Escolar*3, María Concepción Gil-Rodríguez1,2

1University of Zaragoza, Zaragoza, Spain, 2CerTest Biotec S.L, San Mateo de Gállego, Spain, 1University of Zaragoza, Zaragoza, Spain

**Background:** The real-time polymerase chain reaction (qPCR) has become a powerful tool for rapid diagnosis. It is well-known that diverse substances can interfere in the reaction producing unintended results. In addition, there are few studies about the affection in qPCR of diverse drugs used from patient’s treatment. This study tested 46 substances (antacids, antibiotics, antipyretics, antitussives, antivirals, expectorants, laxatives, probiotics, …), in several concentrations, used for patient treatment or ingested by the patients in order to evaluate their inhibitor/enhancer potential.

**Materials/methods:** Several concentrations of each substance were added directly over the qPCR reaction mix. The qPCR assay used in this study was VIASURE Flu A, Flu B & RSV Real Time PCR Detection Kit that detected four targets in four different reactions. qPCR assays run on thermocycler CFX96TM Real-Time PCR Detection System (Bio-Rad). The 46 compounds were evaluated with two different approaches, based on the quantification cycle (Cq) and the end-point fluorescence intensity (FI); and based on the individual amplification efficiency (EA) of each individual reaction calculated with LinRegPCR program Version 2017.1. The maximum concentration of no interference (MCNI) of each substance was calculated for both approaches.

**Results:** MCNI values for both approaches were very similar; however, the one based on Cq and FI was more restrictive. Graphical representations showed that compounds could follow four general behaviors: a total inhibition in one or several concentrations (67.4%), partial inhibition (26.1%), enhancement (4.3%) and no affectation (2.2%). In addition, two specific behaviors have been also identified; the more affection over retrotranscription compared to DNA polymerase reaction (10.9%) and the gradual fall of the fluorescence with dependence on the fluorophore (2.2%).

**Conclusions:** The comparison performed with previous studies has been made carefully due to methodologies were different. Several drugs not described in the literature to date as inhibitors of qPCR were identified, which facilitates the success of qPCR for rapid diagnosis, and particularly for developing pre-qPCR processing systems. Also, the results suggested that the qPCR assay used in the present study withstood higher inhibitors concentrations.

Primary evaluation of three Aspergillus PCRs compared to galactomannan assay
Laura Verdurme*1, Marco Gama1, Eric Hedbaut2
1Cerba laboratory, Saint Ouen l’Aumone, France

Background: Invasive aspergillosis remains the leading cause of invasive fungal infection in immunocompromised patients. PCR-based methods are increasingly used. Here we present preliminary evaluation results of three different kits of Aspergillus PCR.

Materials/methods: 11 bronchoalveolar lavage (BAL) and 9 serum samples from 13 patients previously tested in Aspergillus galactomannan (GM) assay were extracted using Janus Chemagic360. DNA was analysed with three commercially available PCR kits: Fungiplex (Brucker), MycoGenie (Ademtech), Aspergillus ELiT MGB (Elitech). All PCR have been done on CFX96 (Biorad).

Then, we analysed with Aspergillus ELiT 10 sterile water samples and 6 strains from Cap Survey mycology evaluation: 4 Aspergillus (ochraceus, terreus, fumigatus, flavus), 1 Penicillium and 1 Scopulariopsis spiked in sterile water and diluted 1:100.

Results: Among 17 GM positive samples, 7 were positive by Fungiplex assay, 10 by MycoGenie and Elitech assays. Four serum samples from patients GM positive in BAL were tested, three remain negative in PCR.

Detection of the 4 Aspergillus was good, Scopulariopsis was not detected but Penicillium was also detected. All 10 water samples had ct > 38, considered as negative.

Conclusions: MGB and Mycogenie show better results than Fungiplex. Discrepancies with galactomannan should be investigate to determine if PCR is more specific than galactomannan or less sensitive.

Abstract 4461

Hospital-based surveillance of influenza in Switzerland: a pilot study, season 2018/19
Anne Iten1, Amaury Thiabaud*, Nicolas Troillet3, Laurence Senn4, Domenica Flury5, Stefan P. Kuster6, Carlo Balmelli7, Céline Gardiol8, Ana Rita Goncalves Cabecinhas9, Laurent Kaiser10, Olivia Keiser2

1Hôpitaux Universitaires de Genève (HUG), Service PCI, Genève, Switzerland, 2University of Geneva, Institut de Santé Globale, Geneva, Switzerland, 3Valais Hospital, Central Institute, Sion, Switzerland, 4Lausanne University Hospital, Lausanne, Switzerland, 5Kantonsspital St.Gallen, Infektiologie/Spitalhygiene, St. Gallen, Switzerland, 6University Hospital of Zürich, Zürich, Switzerland, 7EOC Ente Ospedaliero Cantonale, Lugano, Switzerland, 8Federal Office of Public Health, Bern, Switzerland, 9Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland

Background: Until 2018, the national reporting system for influenza in Switzerland was limited to a Sentinella system – voluntary reports of influenza-like illnesses by primary care clinicians, and laboratory characterisation of circulating virus strains during and off the influenza season. No surveillance of hospitalised cases existed nationally, each hospital having their own surveillance system. With support from the Federal Office of Public Health, we developed a pilot study for hospital-based influenza cases in Switzerland.

Materials/methods: Six major swiss hospitals participated in the pilot study and collected data following the WHO recommendations via a standardised questionnaire [demographic data, information on the influenza episode, optional information about the patient’s health]. Data were collected in a secure REDCap database. Data quality checks and descriptive analyses were reported weekly. Another questionnaire was used to assess the quality of the pilot system and to identify staff practices.

Results: From 01.11.2018 to 31.05.2019, 1700 cases were declared. The influenza epidemic started during week 2018-47 in Western Switzerland, and three to four weeks later in other sites. Most patients were elderly (67.2% over age 65). The majority of cases (98.5%) was due to influenza A. The proportion of weekly nosocomial cases peaked to 30%, with variation between sites. The hospitals adopted security measures such as wearing of masks for patients, staff, and visitors; Droplet specific measures; and cohorting when possible. The system was deemed useful to obtain an overview of the overall situation and to get prepared for the epidemic. The workload was substantial: from a few minutes to collect the obligatory information to 1.5h for the optional information; the allowance for data collection proved important for the success of the study, but sometimes insufficient.

Conclusions: Our pilot system allowed us to get a better understanding of the distribution and spread of severe influenza cases in Switzerland. Simplification of the questionnaire, direct import of existing data, automated analysis, and additional tools for epidemic management will help to reduce the workload. In participating hospitals, the pilot system has proved feasible, but might not be sustainable without additional advantages for the sites. Inclusion of other smaller hospitals is now needed.

Are resistance rates among bloodstream isolates a good proxy for other infections: analysis from the BSAC resistance surveillance programme

Carolyne Horner1, Shazad Mushtaq2, David Livermore3

1Birmingham, British Society for Antimicrobial Chemotherapy, Birmingham, United Kingdom, 2London, Public Health England, London, United Kingdom, 3Norwich, University of East Anglia, Norwich, United Kingdom

Abstract third-party references: The British Society for Antimicrobial Chemotherapy Standing Committee on Resistance Surveillance

Background: Resistance rates in bacteraemia isolates are often used as a general measure of resistance prevalence but may not represent other infection types. The BSAC Resistance Surveillance Programme monitors antimicrobial susceptibility in the major organisms of bacteraemia and respiratory tract infections (LRTI) in the UK and Ireland. We compared resistance rates between these two settings.

Materials/methods: 24 laboratories collected isolates, to a fixed annual quota per species group. Bloodstream isolates were collected during calendar 2018 and LRTI isolates between Oct 2017 to Sept 2018. MICs were determined centrally by BSAC agar dilution.

Results: 2788 isolates were reviewed, 1670 from blood and 1118 from LRTI. Respiratory Pseudomonas aeruginosa and Streptococcus pneumoniae showed higher resistance rates than for bloodstream isolates. For P. aeruginosa (209 from blood; 179 from LRTI), respective resistance rates were ciprofloxacin (18% vs. 7%), imipenem (17% vs. 8%), meropenem (9% vs. 4%), piperacillin/tazobactam (10% vs. 4%), ceftazidime (6% vs. 2%), and gentamicin (4% vs. 2%). For S. pneumoniae (209 blood; 325 LRTI) rates were penicillin MIC>0.06 mg/L (15% vs. 6%), erythromycin (15% vs. 7%), clindamycin (11% vs. 6%), tetracycline (14% vs. 10%). The trend for S. pneumoniae persisted even when multiresistant serotype 15A isolates were excluded. In contrast, approximate parity in resistance rates among bloodstream and LRTI isolates was seen for most agents against Enterobacterales (797 blood, 424 LRTI) and Staphylococcus aureus (456 blood, 190 LRTI). Exceptions included a higher rate of amoxicillin-clavulanate resistance for LRTI Escherichia coli (61% vs. 41%, based on 475 bloodstream and 241 LRTI isolates), and a higher rate of colistin resistance in bloodstream Enterobacter cloacae (12% vs. 7%, based on 159 bloodstream and 73 respiratory isolates). MRSA comprised 7% of S. aureus from blood and 10% from LRTI.

Conclusions: Rates of resistance among bloodstream isolates are a reasonable proxy for most antibiotics for Enterobacterales and S. aureus but not for Pseudomonas or S. pneumoniae where resistance to all agents was consistently more prevalent in LRTI irrespective of agent. Collection of surveillance data for different infection types is crucial for our understanding of antibiotic resistance trends.

Epidemiology of influenza in Thailand: findings from near real-time laboratory-based influenza system, a network of 40 hospital in Thailand, 2010-2019

Theethach Eamchotchawalit*, Phunlerd Piyaraj2,3, Putt Narongdej1, Sakarn Charoensakulchar1

1Phramongkutklao College of Medicine, Bangkok, Thailand, 2Phramongkutklao College of Medicine, Department of Parasitology, Bangkok, Thailand, 3Bangkok Hospital, Bangkok health research centre (BHRC), Bangkok, Thailand

Abstract third-party references: Bangkok Dusit Medical Service (BDMS), Phramongkutklao College of Medicine

Background: Influenza is an acute viral disease of the respiratory tract which is characterized by fever, headache, myalgia, cough, sore throat and cough. Although recent efforts from some Asian countries to describe burden of influenza disease and seasonality, these data are missing for the vast majority, including the private section of Thailand. A near real-time laboratory-based influenza surveillance system, the Bangkok Dusit Medical Services surveillance system (BDMS-SS), in a network of 40 hospitals was implemented in 2017 aiming to determine influenza strains circulating in the private hospitals of Thailand and know characteristics, trend and burden of influenza viruses.

Materials/methods: We used influenza data from BDMS-SS from 2010 to 2019 for this analysis. We obtained the data by monitoring patients with influenza-like illness (ILI) at a network of 40 private hospitals across Thailand. Throat-swab specimens in viral transport media were collected and transported to the National Healthcare Systems Co., Ltd. within 24 h of collection using a cold-chain system. The respiratory samples were tested by rapid influenza diagnostic tests and real-time reverse transcription polymerase chain reaction.

Results: From January 2010 to November 2019, a total of 1,300,594 subjects were tested and 320,499 cases of influenza were identified. Of those positive cases, 116,317 (36.3%) were influenza type B, 185,512 (57.9%) were influenza A unspecified subtype, 8,833 (2.7%) were influenza A(H1N1)pdm2009 and 6,371 (1.9%) were seasonal influenza A(H3N2). Positive rate were 50.5 and 49.5 in female and male, respectively. Positivity rate was 41.4% in persons 15-49 years followed by 29.1% in 15-14 years, 17.6% in under five children and 11.7% in > 49 years. In 2018-2019 season, the highest positivity rate observed in February and March (39.3%) followed by April (34.2%), January (32.3%) and September (28.9%) while the lowest positivity rate was in May (18.1%).

Conclusions: In Thailand, seasonal Influenza A(H3N2), Influenza A(H1N1)pdm2009 and Influenza B viruses were circulating during 2010-2019. In last season, positivity rate and number of cases peaked in February and March. Influenza is one of public health problems in Thailand and the need to introduce influenza vaccine and antivirus is important to prevent and treat the disease in future.
Abstract 4467

Genomic evidence that the recurrence of Salmonella enterica serovar Weltevreden in human salmonelloses in Asia is triggered by the aquatic environment

Yaovi M. G. Hounmanou1, Anders Dalsgaard1, Tirzania Sopacua1, Gazi Noor Uddin1, Pimlapas Leekitcharoenphon2, Rene S. Hendriksen2, Marianne Larsen1

1University of Copenhagen, Frederiksberg, Denmark, 2Danish Technical University, Lyngby, Denmark

Background: Salmonella Weltevreden is one of the top and persistently reported cause of human Salmonellosis throughout Asian countries including Vietnam, Thailand, Singapore and China. Studies have also reported that S. Weltevreden is frequently associated with seafood. The present study aimed to determine the genetic characteristics supporting survival of S. Weltevreden in the aquatic environment and their relatedness to clinical strains.

Materials/methods: S. Weltevreden were isolated from tilapia and shrimp collected on farms in China and Vietnam and subjected to WGS. Genome-wide analyses were performed with 12 of the isolates along with a collection of 60 clinical strains.

Results: The S. Weltevreden isolates were of MLST ST-365 and harbored SPI-5, which host the major virulence genes associated with human infection. Ten of the isolates harbored the IncFII (S) plasmid with one containing resistance genes (strA/B, sul2 and tetA). Phylogenetic analysis revealed genetic relatedness between shrimp isolates from Vietnam and tilapia from China with about 20 SNPs. In a global context, our isolates clustered within the continental Weltevreden lineage, originating mostly from clinical samples with as low as seven SNPs. The pangenome analysis of clinical and environmental strains of this cluster revealed a pangenome size of 7891 genes including a core-genome of 4892 genes. The accessory genome shows that the genetic content of the environmental strains is significantly similar to clinical strains [Benjamini p>0.05]. The genome-wide comparison against S. Typhi, S. Typhimurium and S. Enteritidis, revealed that S. Weltevreden possess specific Fructose 1,6-Bisphosphatase, nucleoside triphosphate hydrolase, and DEAD/DEAH box helicases involved in adaptation to changing environments and stress response contributing to survival of S. Weltevreden in aquatic environments. Environmental strains also present molecular adaptation machinery for attachment, survival and defense like the magnesium and cobalt efflux protein (CorC), and the multidrug efflux pump component (MtrF) conversed in their defense system enabling persistence in the aquatic matrices favoring human exposure via consumption of contaminated seafood.

Conclusions: Although their reservoirs remain to be studied, S. Weltevreden are genetically fit to survive the aquatic environment and possess virulence factors like clinical strains, to which they are phylogenetically related both in the core and accessory genomes.

Abstract 4471

Characterisation of healthy gut microbiome subjects following a mediterranean diet

Silvia Noemi Vazquez Cuesta*1, Nuria Lozano1, Laura Villar Gomara1, Luis Alcalá1, Mercedes Marín1, Patricia Muñoz1, Emilio Bouza1, Elena Reigadas Ramirez1

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

Abstract third-party references: On behalf of the HGUGM Microbiome Project

Background: It is essential to define the microbiome in a healthy status in order to establish relationships between microbiome and disease. There are few studies assessing the human gut microbiome of a healthy population following a Mediterranean diet. This type of diet might influence the composition of the gut microbiome. The objective of this study was to characterize the intestinal microbiota of healthy individuals who follow a Mediterranean diet as a control cohort for future microbiota studies.

Materials/methods: Fecal samples were collected from healthy subjects, informed consent and a dietary survey was obtained. The hypervariable V4 region of the 16s rRNA gene was sequenced on an Illumina MiSeq platform. Sequenced data preprocessing, OTU clustering and taxonomic classification were done using MOTHUR software, RDP and SILVA database. Alpha and Beta diversity analysis and statistical analysis were conducted by MOTHUR, QIIME 2 and R. Enterotype analysis was performed using www.enterotypes.org web tool. Adherence to a Mediterranean diet was evaluated using Med-DQI.

Results: A total of 60 healthy subjects were enrolled (ongoing study). We observed significant differences regarding sex, females had a higher alpha diversity (p=0.025). Across age groups (Figure), we observed significant differences regarding richness (p=0.005), alpha-diversity (p<0.001), and beta-diversity (p<0.001). Bifidobacteriaceae was more predominant in children and teenagers than in adults (p=0.045), teenagers also exhibited very high levels of Clostridiaceae (p=0.035) and Coriobacteriaceae (p=0.002). Desulfovibrionaceae was characteristically low at early and late stages of life (p=0.005) and Ruminococcaceae was significantly lower in children (p=0.032). As for Mediterranean diet adherence (n= 39 subjects), 44.7% were classified as "High" adherence with a significantly greater alpha-diversity than the "Medium" group (p=0.012). Enterotype classification was as follows: "High" [35.3% enterotype-Bacteroides, 23.5% enterotype-Firmicutes, enterotype-Prevotella 41.2%] "Medium" [36.4% enterotype-Bacteroides, 27.3% enterotype-Firmicutes, enterotype-Prevotella 36.4%].

Conclusions: Our results show that sex and age group are important factors to take into account in microbiome comparative studies including healthy controls since there are important differences in terms of microbial diversity and specific microbial group abundances. We found no predominant enterotype according to Mediterranean diet adherence. However, a high adherence to Mediterranean diet resulted in a greater alpha diversity.

Abstract 4472

Epidemiology of nosocomial highly resistant microorganism outbreaks in the Netherlands

Ascelijn Reuland*1,2, Annelot Schoffelen1, Paul Bijkerk1, Paul Bergervoet1, Sabine C. De Greeff1, Christina Vandenbroucke-Grauls4

1Centre for Infectious Disease Control (CIb), Department for Epidemiology and Surveillance, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 2Department of Medical Microbiology, University Medical Centre Utrecht, Utrecht, Netherlands, 3Saltro Diagnostic Centre for Primary Care, Utrecht, Netherlands, 4Department of Medical Microbiology, Amsterdam University Medical Centre, location VUMc, Amsterdam, Netherlands

Abstract third-party references: On behalf of the SO-ZI/AMR group

Background: In 2012, the Early warning and response meeting of Healthcare-associated Infections and AntiMicrobial Resistance (SO-ZI/AMR) was founded. The purpose of this national structure is to timely identify large-scale outbreaks in hospitals and long-term care facilities (LTCFs) and to prevent further spread of highly resistant microorganisms (HRMO) through early warning and notification. The SO-ZI/AMR assesses the risk of the outbreak for public health, monitors the course of the outbreak and communicates potential risks for public health. Outbreaks are categorized into one of six phases: 1 (lowest) to 5 (highest risk) and phase 0 once an outbreak is completely contained. An outbreak that lasts more than 2 months is categorized as phase 2. In case of a potential threat to public health it will be classified as phase 3; phase 4 and 5 describe potential management issues.

Materials/methods: For each outbreak the following data are collected: duration, type of HRMO involved, reason of notification, number of patients involved, phase of the outbreak, and infection control measures taken.

Results: Data were collected on outbreaks that occurred between April 2012 through October 2019. In total 395 outbreaks were reported from 156 different healthcare facilities: 76 hospitals and 80 LTCFs (mean: 4.5/month). Outbreaks with methicillin-resistant Staphylococcus aureus (MRSA, n=148) and vancomycin-resistant enterococci (VRE, n=100) were most often notified. Thirty-five outbreaks with carbapenemase-producing strains were reported. Most outbreaks (97%) were classified as phase 1 or phase 2 and were controlled quickly (within 2 months). Twelve outbreaks were evaluated as phase 3, involving MRSA (2), Clostridium difficile (2) and VRE (8). C. difficile and VRE outbreaks had the longest duration (maximum 23 months). One outbreak, in 2018, with New Delhi metallo-beta-lactamase (NDM)-producing Citrobacter freundii was classified as phase 4, but could be scaled down to phase 3 after two months, after additional control measures were taken.

Conclusions: The SO-ZI/AMR has resulted in a transparent national overview of outbreaks in Dutch hospitals and LTCFs. Outbreaks with HRMO and other pathogens occur occasionally, but are usually quickly controlled. Only one outbreak progressed to phase 4, no outbreaks progressed to phase 5.

¹Servicio de Medicina Interna. Hospital Rio Carrión, Palencia, Spain, ²Servicio de Microbiología. CAUSA. Instituto de Investigación Biomédica de Salamanca (IBSAL). Centro de Investigación en Enfermedades Tropicales de la Universidad de Salamanca (CIETUS), Universidad de Salamanca, salamanca, Spain, ³Servicio de Microbiología. Hospital Rio Carrión, Palencia, Spain, ⁴Servicio de Microbiología. CAUSA, salamanca, Spain, ⁵Centro de Atención Primaria, Puente San Miguel., Santander, Spain, ⁶Servicio de Medicina Interna. Sección de Enfermedades Infecciosas. CAUSA. IBSAL. CIETUS, Universidad de Salamanca, salamanca, Spain, ⁷Departamento de Medicina Interna. Hospital Universitario M. Valdecilla. IDIVAL. Santander. Cantabria, Santander, Spain

Background: Complicated urinary tract infections (UTIs) are frequently caused by Enterococcus spp.. Antibiotics that are usually recommended in guidelines are not useful for the management of this infection. Recently, guidelines have suggested the coadministration of antibiotics in patients at risk, but the risk factors for UTIs caused by Enterococcus have not been well defined.

The objective of this work is to characterise the UTI by Enterococcus knowing its epidemiology, risk factors associated with bacteraemia and general mortality, evaluating the empirical treatment.

Materials/methods: Retrospective study in patients with a diagnosis of UTIs caused by Enterococcus spp.. We compared the results with those of a random sample of patients with complicated UTIs caused by Escherichia coli. We conducted bivariable and multivariable analyses.

Results: We found 106 in-patients with UTIs caused by Enterococcus spp., 56 of whom had positive blood cultures. Distribution by species: 83% E. faecalis and 17% E. faecium, with a Charlson comorbidity index of 5.9±2.9. Only male sex with OR 2.8(95%CI 1.2-6.4), nosocomial infection with OR2.8(95%CI 1.1-7), urinary catheter with OR4.5(95%CI 1.8-11.3), urinary cancer with OR6.4(95%CI 2.1-19.4), and previous antimicrobial treatment with OR4.3(95%CI 1.8-10.2) were independent predictors of Enterococcus infection. The only risk factors for enterococcal bacteraemia were the presence of urothelial tumor and solid organ transplantation (p<0.05). Overall, in-patient mortality was 16.5%, which was associated with a higher SOFA score (>4), severe comorbidity such as immunosuppression, malignant hemopathy and nephrostomy, or Enterococcus faecium species and its pattern or resistance to ampicillin or vancomycin (p<0.05). Appropriate empiric antibiotic therapy was not associated with a better prognosis (p>0.05).

Conclusions: Enterococcus spp. is a frequent cause of UTI characterized by a profile of risk factors: male sex, high Charlson index, urinary catheter, previous antibiotic treatment, urological cancer and several types of immunosuppression. High mortality secondary to a severe clinical setting and high comorbidity may be sufficient reasons for implementing empiric treatment of patients at risk, although we did not show a higher survival rate in patients with this treatment strategy.

Abstract 4475

**Efficacy of extended duration use of dalbavancin in pyogenic spondylodiscitis: a preliminary report**

Marco Libanore*1, Roberto Bicocchi2, Massimo Borrelli3, Roberto Pora4, Ilaria Rambaldi5, Giuseppe Caruso6, Pasquale De Bonis7, Rosario Cultrera8

1Department of Infectious Diseases, St Anna Hospital and University, Ferrara, Italy, 2Department of Infectious Diseases, St Anna Hospital and University, Ferrara, Italy, 3Unit of Neuroradiology, St Anna Hospital and University, Ferrara, Italy, 4Unit of Clinical Microbiology, St Anna Hospital and University, Ferrara, Italy, 5Department of Nuclear Medicine, St Anna Hospital and University, Ferrara, Italy, 6Department of Orthopedic, St Anna Hospital and University, Ferrara, Italy, 7Department of Neurosurgery, St Anna Hospital and University, Ferrara, Italy, 8University Infectious Diseases, St Anna Hospital and University, Ferrara, Italy

**Background:** dalbavancin is a lypoglycopeptide with potent activity against gram positive microorganisms, a long half–life, a favourable safety profile, and a high concentration in bone, which makes it an interesting alternative for treatment of osteo-articular infections. Experimental studies have demonstrated that dalbavancin 1500 mg IV on days 1 and 8 determine tissue exposure over the MIC for difficult gram positive for 8 weeks, maximizing the initial exposure to treatment

**Materials/methods:** in a open label study 12 patients with pyogenic spondylodiscitis were enrolled, 6 males and 6 females, mean age 66,8 years ( range 52-84). 2/12 showed cervical localization, 6/12 dorsal e 4/12 lumbar. The etiology was: MRSA 5/12; MSSA 2/12; Staphylococcus warneri 1/12; Streptococcus gallolyticus 1/12; Propionebacterium spp. 1/12; Unknown 2/12. 10/12 vertebral biopsy were performed. Two dose of Dalbavancin 1500 mg IV on days 1 and 8 were administered, and other two doses, once weekly, were subsequently administered, after an interval of six weeks. Significative adverse events were not observed All patients before to start the treatment with Dalbavancin were submitted to SPECT or PET These were repeated after fifteen weeks

**Results:** among 12 cases of spondylodiscitis 10 were cured (83,4%), 1 were considered improved (8,3%) and 1 with initial response (8,3%) died for other cause.

**Conclusions:** our preliminary report show that dalbavancin is a well tolerated antibiotic and the regimen with 2 repeated doses with six week interval between them is associated with a high cure rate in patients with pyogenic spondylodiscitis. These data would be confirmed on numerous case studies.

**Presenter email address:** m.libanore@ospfe.it
Determining the lung microbiome of chronic obstructive pulmonary disease patients from hospitals in Pretoria, South Africa using IS-Pro method and 16S rDNA sequencing

Tanweer Goolam Mahomed*, Remco Peters1,2,3, Gert H. J. Pretorius4, Akhter Goolam Mahomed5, Veronica Ueckermann1, Anton Stoltz1, Marleen Kock1,6, Marthie M. Ehlers1,6
1University Of Pretoria, Pretoria, South Africa, 2Maastricht University Medical Center+, Maastricht, Netherlands, 3Foundation for Professional Development, Research Unit, East London, South Africa, 4Synexa Life Sciences, Cape Town, South Africa, 5Louis Pasteur Private Hospital, Pretoria, South Africa, 6National Health Laboratory Services - Tswane Academic, Pretoria, South Africa

Background: Chronic obstructive pulmonary disease (COPD) is a leading cause of death worldwide and is highly prevalent in South Africa. However, despite this, there is limited information on the lung microbiome in COPD patients. There are several different methods that can be used to study the microbiome (targeting 16S rDNA gene) including next generation sequencing and the IS-Pro method. The aim of this study was to compare the IS-Pro method and 16S rDNA sequencing for routine use in identifying the lung microbiome in COPD patients.

Materials/methods: Twenty-four sputum specimens were collected from COPD patients in Pretoria. Bacterial DNA was extracted using Isolate II Genomic DNA kit (Bioline, United Kingdom). The DNA was processed in two ways: i) V1-V3 sequencing of 16S rDNA gene on MiSeq (Illumina, USA) at Inqaba Biotec (Pretoria, South Africa) and analysed using QIIME2 and ii) using the IS-Pro method (inBiome, Netherlands and Synexa Life Sciences, Cape Town)

Results: Results were only available for 23 of the 24 samples. The IS-Pro method detected six phyla across 23 samples with the dominant phyla being Proteobacteria, Firmicutes and Fusobacteria/Bacteroidetes. Analysis with QIIME2 identified 15 phyla with the dominant phyla being Firmicutes, Bacteroidetes/Proteobacteria and Actinobacteria. The most common genera in both methods were Haemophilus and Streptococcus. The IS-Pro method was able to identify 67% of the operational taxonomic units (OTUs) to a species level (the rest of the OTUs were unclassifiable at a genus level), whereas QIIME only identified 33% of the OTUs.

Conclusions: A major limitation of the IS-Pro method is that it is only able to detect members of six phyla: Actinobacteria, Bacteroidetes, Firmicutes, Fusobacteria, Proteobacteria and Verrucomicrobia. As a result, the uncommon phyla are missed. This may result in over-reporting of some phyla, as the primers used in the kit select for these phyla; which may explain the higher prevalence of Proteobacteria using the IS-Pro method. However, the two methods performed comparatively at the genus level of identification, with the IS-Pro method performing better at species level identification. This suggests that the IS-Pro method may be more useful as a screening tool for diagnostics.

Does cefepime require dose adjustments in critically ill patients on extracorporeal membrane oxygenation? A pharmacokinetic study

Vesa Cheng1, Kiran Shekar2, Mohd Hafiz Abdul Aziz2, Hergen Buscher3, Amanda Corley2, Eileen Gilder4, Arne Diehl2, India Lye2, Shay Mcguinness1, Rachael Parke6, Claire Reynolds1, Susan Welch3, John Fraser2, Jason Roberts1

1The University of Queensland, Saint Lucia, Australia, 2The Prince Charles Hospital, Chermside, Australia, 3St Vincent’s Hospital Sydney, Darlinghurst, Australia, 4Auckland Hospital, Auckland, New Zealand, 5Alfred Hospital, South Yarra, Australia

Background: The increase use of extracorporeal membrane oxygenation (ECMO) in adult intensive care units (ICUs) has led clinicians to re-evaluate the use of conventional dosing regimens in this patient population. Neonatal studies have suggested modified antimicrobial dosing regimens are necessary in the presence of ECMO to attain PK/PD targets for optimised bacterial kill and clinical cure. However, due to significant differences in physiology, these findings cannot be safely extrapolated to the adult population. Empirical antibiotics such as ceftriaxone have no defined, titratable end-point; and this may lead to possible sub- or supra- therapeutic plasma levels in this group of critically ill patients.

The aim of this study is to describe the pharmacokinetics (PK) of cefepime in critically ill patients receiving ECMO. Also, through improved understanding of ECMO-induced PK effects, propose dosing strategies that are more likely to attain the PK/PD target of 60-70% T>MIC to optimise therapeutic outcomes.

Materials/methods: This study was a multi-national, open-label study, designed to describe the PK of cefepime over one dosing interval. Critically ill adults with severe cardiac and/or respiratory dysfunction from six intensive care units in Australia, New Zealand, Switzerland and Korea were eligible for recruitment. Serial blood samplings were taken over pre-defined time points over one dosing interval. Centralised bioanalysis occurred at the University of Queensland to determine plasma cefepime concentrations through validated chromatographic methods. The concentration-time data was then used to generate pharmacokinetic parameters through non-compartmental methods.

Results: Eight critically ill patients were recruited in the study, one was excluded due to insufficient data points collected [Table 1]. In this cohort, the median [IQR] estimates for volume of distribution, clearance, elimination half-life and elimination rate constant were 0.13 [0.12–0.25] L/kg, 0.02 [0.01–0.04] L/h/kg, 7.5 [3.5–8.7] h and 0.14 [0.10–0.20] h⁻¹ respectively. Although large variations were observed in these parameter estimates, the values are generally consistent with published studies in critically ill patients who are receiving ECMO.

Conclusions: The heterogeneity of results demonstrates significant pharmacokinetic variability. Further analysis to develop robust dosing guidelines to optimise pharmacotherapy in these patients is required.

Abstract third-party references: Public Health England

Background: Whole Genome Sequencing (WGS) is a validated method for the identification of Mycobacterium tuberculosis and prediction of first-line drug sensitivities through detection of polymorphisms in the DNA sequence followed by comparison to a reference database. The database of mutations must be carefully curated as new genetic mutations are identified and information on phenotypes becomes available. These updates must be rigorously tested before adoption into routine work. This genetic data is also compared to previously sequenced isolates to determine genetic relatedness. This permits identification of clusters of transmission and allows public health teams to target at-risk individuals and contain outbreaks.

Materials/methods: In November 2018 we noted several isolates with the mutation L203L, a synonymous mutation of CTG to CTA located within the fabG1 gene, functioning as a promotor mutation to inhA. Our data supported previous evidence that this mutation conferred Isoniazid resistance but required rigorous testing before incorporation into the curated database in August 2019. Following this, in October 2019 we identified an individual who clustered (0 Single Nucleotide Polymorphisms) with two others. This new case was predicted Isoniazid resistant due to L203L by WGS, discordant from the two prior cases predicted sensitive in Spring 2019.

Results: On further analysis, these earlier two cases also showed L203L as the sole mutation present within the genomes, but these were not identified in our genetic database at time of analysis. All three cases had phenotypic isoniazid resistance when tested following WGS of the 3rd case. All cases and contacts were previously or currently being treated with isoniazid-containing regimens, which may have been inadequate, thus requiring prompt management. Our data supports the determination that this synonymous mutation confers phenotypic resistance. The overall prevalence of the L203L mutation is low, at 0.3% of sequenced isolates at Public Health England.

Conclusions: Determining genetic relatedness is important as this identifies developing clusters of transmission and can assist identification of uncommon genetic mutations that may not have been detected initially using the curated database. Regular updates to these databases are necessary as identification of rare mutations can have significant clinical and public health impact.

Improved detection of acid-fast bacteria using an automated slide scanner with integrated deep learning analysis
Lucas Horvath1, Siegfried Haenselmann*2, Heiko Mannsperger2, Svenja Degenhardt2, Katharina Last1, Stefan Zimmermann1, Irene Burckhardt1

1University Hospital of Heidelberg, Department for Infectious Diseases, Microbiology and Hygiene, Heidelberg, Germany, 2Meta-Systems Hard & Software GmbH, Altlußheim, Germany

Background: Microscopy of auramine stained sputum is the most used method for the initial detection of tuberculosis (TB). However, manual microscopy of auramine slides is tedious and suffers from low sensitivity. By pre-analyzing slides and presenting the condensed, relevant information to the clinician, deep learning powered automated scanning systems promise considerable improvements of this workflow.

Materials/methods: We combined a fully automated slide scanning system (Metafer, MetaSystems) with a deep neural network (DNN) classifier in order to establish an automated workflow for detection of acid-fast bacteria in auramine slides. A binary DNN classifier was trained to detect acid-fast bacteria in small image tiles of 144 x 144 pixels from 82 routine slides. The classifier was then integrated into the scanning system, allowing it to present a gallery of the most relevant image tiles (i.e. tiles that most probably contain bacteria) and to propose a slide classification on WHO-scale. For clinical validation, 531 independent slides taken from routine workflow were scanned and pre-analyzed. The scanned area per slide is equivalent to 300 microscope fields of view using a 40x objective with 23 mm oculars. A microbiologist unaware of the reference result evaluated each slide using the information given by the system. We compared the results from the microbiologist to manual microscopy, the system’s proposal and the culture results as the reference.

Results: Pre-analysis by the DNN classifier hugely reduced the manual review time of the clinician to around 10 s per slide on average. Compared to manual microscopy, the sensitivity increased from 60,7% (34/56 positive slides detected) to 71,4% (40/56 positive slides detected). The proposed classification given by the system without the clinician’s review showed the highest sensitivity (96,4%, 54/56 positive slides detected), however at the cost of specificity.

Conclusions: Automated slide scanning with assisted classification of auramine stained bacteria by deep learning saves working time and considerably improves the sensitivity of TB microscopy. Typical for deep learning systems, the performance of the pre-analysis improved with the amount of training data. Updating the system with additional training data from time to time is expected to further boost its performance even after deployment.

Antimicrobial susceptibility in *Clostridioides difficile* varies according to European region and isolate source

Jane Freeman*1, Virginie Viprey1, Valerija Tkalec2, Duncan Ewin1, William Spittal1, Emma Clark1, Jonathan Vernon1, Warren Fawley3, Anthony Benson1, Georgina Davis1, Maja Rupnik2, Mark H. Wilcox1, Kerrie Davies2

1Healthcare Associated Infections research group, University of Leeds, Leeds, United Kingdom, 2National laboratory for Health, Environment and Food, NLZOH, Maribor, Slovenia, 3C. difficile ribotyping network for England and Wales, Public Health England, Leeds, United Kingdom

Abstract third-party references: on behalf of the COMBACTE-CDI consortium

**Background:** *C. difficile* (CD) epidemiology continues to evolve: recent studies have identified emerging and resistant ribotypes (RT) that are country-associated. The COMBACTE-CDI project provides an ideal opportunity to examine CD epidemiology and resistance across Europe.

**Materials/methods:** All diarrhoeal faecal samples sent to 119 recruited testing facilities from 12 European countries, on two sampling days, were collected. All samples were cultured for CD on CCEY agar; isolates were typed by PCR-ribotyping and toxino/typing. Contemporaneous CD isolates were collected from animals in the same countries. Metronidazole, vancomycin, fidaxomicin, moxifloxacin, clindamycin, imipenem, tigecycline and rifampicin MICs for 215 clinical and 44 animal isolates were determined by Wilkins-Chalgren agar dilution. MICs for each antimicrobial were scored as sensitive=0; intermediate=1; resistant=2 for each isolate according to published breakpoints and added to generate a cumulative resistance score (CRS).

**Results:** Fidaxomicin was the most active treatment agent (geometric mean for both clinical and animal isolates=0.03mg/L) but reduced susceptibility was observed in n=2 (RT01 2 & RT066) isolates (1mg/L). Geometric mean metronidazole MICs (clinical isolates) were 0.3mg/L, but were elevated among predominating epidemic RT027 (2.17mg/L) and Eastern European-associated RT181 (1.03mg/L). RT027 and RT181 also had elevated geometric mean moxifloxacin MICs (16.95mg/L) and 14.25mg/L); clindamycin (9.6mg/L and 10.53mg/L) and rifampicin (20.87mg/L and 0.40mg/L). Two isolates (RT016 and RT002) were metronidazole resistant (MIC=8mg/L) and 9 (8 RT027; 1 RT198) had intermediate resistance (4mg/L). Elevated metronidazole MICs were not observed in animal isolates from Eastern Europe, and no location-linked predominating RTs were observed. Increased geometric mean vancomycin MICs were observed in RT027s, which were more commonly isolated from animals than humans (22 vs 12 respectively), but there was no resistance (MIC>4mg/L). Moxifloxacin and clindamycin resistance was seen in both clinical and animal isolates of multiple RTs. No resistance to imipenem or tigecycline was observed. Average (mean) and median CRS showed that resistance levels among clinical (but not animal) isolates were highest in Eastern Europe (Figure).

**Conclusions:** Epidemiology and resistance differs between clinical and animal CD isolates and by geographic location. Epidemic CD RT027 and highly-related emerging RT181 have increased levels of antimicrobial resistance and are associated with CD infections in Eastern Europe.

Abstract third-party references: FCT/487/15/01/2019/S from Fundação para a Ciência e a Tecnologia.

Background: Biofilm-associated infections are a public health concern in the context of healthcare-associated infections (HAI) such as catheter-related bloodstream infections (CRBSI). Here, we studied two top ten CRBS etiological agents, Enterobacter cloacae and Candida parapsilosis, isolated from a patient with CRBSI in order to understand the role played by biofilms on this HAI.

Materials/methods: E. cloacae and C. parapsilosis were isolated from CVC and peripheral blood by standard procedures. EUCAST guidelines were followed for antimicrobial susceptibility evaluation. Single and/or mixed biofilms were assembled on different materials in Mueller-Hinton broth with 2% glucose. Biofilm assembly was assessed by crystal violet assay and scanning electron microscopy (SEM). Fluorescence in situ hybridization (FISH) was used for identification and to assess microorganisms distribution within the biofilm (3D reconstruction). In addition, Focus Ion Beam (FIB)-SEM was used to assess biofilms assembled on inner and outer surfaces of CVCs and construct tomograms. CVC and hemoculture (HC) isolates were subjected to whole-genome sequencing (WGS).

Results: All Enterobacter and Candida isolates were antimicrobial resistant. Of note, E. cloacae-CVC revealed an additional resistance (ceftolozame-tazobactam) in comparison to the HC isolate. Both microorganisms assembled biofilms on glass, polystyrene and polyurethane. Mixed biofilms were denser when both microorganisms were present from the beginning. Biofilm phenotype was not dependent of biofilm initiation by E. cloacae or C. parapsilosis. FISH and SEM analysis showed that biofilm bottom layer was in all cases richer in E. cloacae. Environmental isolates of the same species were also tested, showing that this biofilm phenotype is not a general feature. Using polyurethane catheters [shape/material factor], we observed denser mixed biofilms richer in EPS. FIB-SEM preliminary results suggest that biofilms assembled on inner and outer catheter surface might differ on microorganisms’ distribution. WGS confirmed the genetic identity of the CVC/HC pairs while corroborating the virulence potential and antimicrobial resistant character of the CRBSI-driving pathogens.

Conclusions: The results suggest that biofilms allow interaction and adaptation of microorganisms belonging to different kingdoms [Bacteria and Fungi]. Adaptation might affect virulence in a transitory or permanent fashion, with potential impact on microorganisms’ potential to cause CRBSI.

Contribution of new tuberculosis cases for multidrug-resistant tuberculosis cases notification in Ethiopia
Dessalegn Negia*1
1Alert Hospital, KNCV Tuberculosis Foundation, Addis Ababa, Ethiopia

Background: The first drug resistance survey (DRS) in Ethiopia, done from 2003 to 2006, showed that 11.8% of previously treated & 1.6% of new mycobacteria tuberculosis cases have rifampcin and/or isonizaide resistant tuberculosis (RR/MDR-TB). According to WHO estimate in its 2018 global TB report, 14% of previously treated and 2.7% of new TB cases in Ethiopia would have RR/MDR-TB. Given that the proportion of previously treated patients accounts just for 4.2% of all notified TB cases, the contribution of new cases for RR/MDR-TB diagnosis would be by far higher than the previously treated if all of them had received drug susceptibility test (DST). So it can be simply estimated that number of RR/MDR TB cases from new TB cases is 3 to 4 times higher than that of the previously treated one.

This study was aimed to determine the contribution of the new TB cases towards the MDR-TB case notification in urban towns of Ethiopia during 2017 to 2018.

Materials/methods: Cross-sectional survey has been conducted on RR/MDR TB patients enrolled in Addis Ababa, Dire Dawa, and Harer during July 1, 2017 to June 30 2018.

Results: As the tables below demonstrate, RR/MDR-TB case finding steadily increasing from quarter to quarter: But the contribution of new cases is still very low (29%) as compared to the previously treated one though it should have been 3 to 4 (67-75%) times higher.

Table 1: Contribution of New TB Cases for RR/MDR-TB Case Finding in Ethiopia, 2018

</table>

Conclusions: Though the trend of MDR-TB case notification is increasing following introduction of gene Xpert for some prioritized new TB cases, the contribution from new TB cases is yet lower than estimated which warrants universal DST for the new TB cases.

Effectiveness of influenza vaccine in preventing medically attended influenza virus infection among healthcare personnel: a test-negative case-control study in Bangkok, Thailand, 2018/19 season

Theethach Eamchotchawalit1*, Phunlerd Piyaraj2,3, Putt Narongdej1, Sakarn Charoensakulchai2

1Phramongkutklao College of Medicine, Bangkok, Thailand, 2Phramongkutklao College of Medicine, Department of Parasitology, Bangkok, Thailand, 3Bangkok Hospital, Bangkok health research centre (BHRC), Bangkok, Thailand

Abstract third-party references: Bangkok Dusit Medical Service (BDMS), Phramongkutklao College of Medicine

Background: Influenza vaccination is the most effective way of preventing influenza infections and it is recommended for the entire health care personnel in Thailand. However, the evidence of influenza vaccine effectiveness (VE) among health care personnel is lacking in Thailand. The objective of this study was to estimate influenza vaccine effectiveness (VE) against laboratory confirmed medically attended influenza illness for the 2018/19 season among health care personnel who at risk for influenza infection in Bangkok, the capital of Thailand.

Materials/methods: Throat swab specimens were collected from patients with influenza-like illness (ILI) presenting to outpatient clinics and tested for influenza virus by RT-PCR, between October 2018 and September 2019. A test-negative case-control design was used to estimate influenza VE against medically-attended laboratory-confirmed influenza in outpatient settings. Cases were influenza-like illness (ILI) patients who tested positive for influenza, and controls were influenza negative patients.

Results: During the 2018/19 season 373 samples were collected; 57 (15.3%) were positive for influenza, 70.2% A un-subtyped and 29.8% B. Adjusted VE against all influenza viruses for this influenza season was -31.7% (95% confidence interval (CI): -40.2 to 66.4), against influenza A un-subtyped, it was 43.9% (95% CI: -30.6 to 75.9) and against influenza B, it was 52.0% (95% CI: -73.9 to 86.8).

Conclusions: The seasonal influenza vaccine was moderately effective against medically attended lab-confirmed influenza infection in health care personnel in Bangkok, Thailand in the 2018-19 influenza season. Increasing seasonal influenza vaccination among health care personnel in Thailand may decrease medically attended influenza-associated ILI cases in this population.

Abstract 4499

Treatment of urinary tract infections in haemodialysis patients: the controversy about antimicrobial urine concentration

Wasim El Nekidy1, Ayah Eshbair1, Mohamad Mooty1, Nizar Attallah2, Antoine Cherfan1, Fadi Hijazi1, Islam Ghazi2

1Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates, 2Philadelphia College Of Pharmacy & Science, Philadelphia, United States

Background: Urinary tract infections (UTI) are common in chronic kidney disease stage 5 requiring hemodialysis (CKD-5D). These infections represent a challenge to diagnose and treat due to lack/dearth of urine production. The Infectious Diseases Society of America (IDSA) suggests utilizing antimicrobials that achieve high urinary concentrations to accomplish sufficient drug exposure. The purpose of this study is to examine the validity of this recommendation in this patient population.

Materials/methods: A retrospective observational study was conducted at our quaternary care hospital between May 2015 and March 2019. The primary end points were to determine the clinical and/or microbiological cure defined as the time to regression of functional urinary symptoms documented by the treating physician and the time to negative culture if was done respectively. Relapse and recurrence data were documented and defined as repeat positive urine culture and/or clinical symptoms within 2 to 4 weeks and three months respectively.

Results: Eleven patients with thirteen encounters of infections were included, 10 had diabetes, and nine had hypertension. The sample mean age was 75±9 years, BMI was 32±9 kg/m², 7 were males, the average duration on dialysis was 13±13 months, and 4 patients were on immunosuppressive therapy. Cystitis was the most common infection for 12 of the patients’ encounters. ESBL E. Coli was the most common pathogen (n=6) and ertapenem 500 mg IV daily was the most frequently used antimicrobial (n=5). Clinical cure was reported in all encounters with no reported microbiological failure (repeated samples were done in 9 encounters). No relapse or recurrence occurred during the follow up period of 3 months for each patient.

Conclusions: Our findings suggest that successful management of UTI in oliguric/anuric patients could be attained through systemic antimicrobials. We hypothesize that free drug concentration equilibrates across the body fluids including the bladder lining epithelial cells and would eradicate the invading pathogens without the need for urinary drug concentration. Our findings need to be replicated in larger studies.

Abstract 4500

Uncovering the role of airborne transmission and asymptomatic contact shedding in outbreaks of scarlet fever
Rebecca Cordery*1,2, Amrit Purba2, Lipi Begum3, Ewurabena Mills4, Mia Mosavie5, Elita Jauneikaite5, Peter Hoffman2, Theresa Lamagni2, Shiranee Sriskandan6
1Public Health England, London, United Kingdom, 2Public Health England, London, United Kingdom, 3Public Health England, London, United Kingdom, 4Imperial College London, London, United Kingdom, 5Department of Infectious Disease Epidemiology, School of Public Health, Imperial College, London, United Kingdom, 6Imperial College London, London, United Kingdom

Background: England is experiencing an upsurge in scarlet fever (SF) and associated outbreaks. Transmission mechanisms are poorly understood but thought to be driven by children with symptomatic disease.

Materials/methods: We undertook a prospective, observational study in nurseries with SF outbreaks to assess impact of antibiotic treatment on detection of Group A Streptococcus (GAS) in cases; prevalence of GAS carriage in community contacts using throat swabs; and presence of GAS in the classroom environment. Transmissibility was assessed using cough plates, hand swabs, environmental swabs and settle plates, with genome sequencing to confirm chains of transmission. Cases were tested on days 1-3 of antibiotics, then weekly for 3-4 weeks. Contacts were tested weekly over 3-4 weeks.

Results: Six classes, comprising 11 SF cases, 17 household contacts, and 142 classroom contacts were recruited. Of 10 cases on treatment, all had negative samples after starting antibiotics, however 4/10 became GAS-positive by week 2 or 3. One untreated case remained positive. GAS was identified in 3/17 household contacts.

GAS prevalence in classroom contacts was high and increased between weeks 1 and 2 in all outbreaks [week 1, 0-19%; week 2, 9-56%; week 3, 18-50%]. 27 contacts (19%) were GAS-positive on two, and 4 on three samples. Surface swabs [n=60] taken in 3 classrooms did not yield GAS except in one instance. Genome sequencing showed clonality of isolates within three classes tested, confirming recent transmission accounted for high carriage. Emergent lineage M1UK accounted for 2/3 outbreaks.

Of 28 classroom contacts with GAS-positive throat swabs, who were tested for transmissibility, 6 (21%) had positive cough plates and/or hand swabs, of whom three remained GAS-positive for 3 weeks. Settle plates were GAS-positive in 2/3 classrooms tested despite being placed in elevated locations.

Conclusions: GAS transmission within classrooms was extensive despite short-term effectiveness of antibiotic treatment. Transmission may occur prior to receipt of antibiotics, underlining the importance of rapid diagnosis and treatment. Despite exclusion of cases and guideline adherence, heavy shedding of GAS by classroom contacts, who may represent subclinical infection or carriage, likely perpetuate outbreaks. Airborne transmission appears to be a key factor, in contrast to environmental contamination.

Abstract 4503

Comparative epidemiological study of MRSA in lactating animals, dairy products, environment and personnel of dairy processing facilities in Northern Greece

Panagiotis Papadopoulos¹, Theofilos Papadopoulos²*,3, Apostolos Angelidis¹, Charalampos Kotzamanidis¹, George Filioussis¹, Antonios Zdragas², Anna Papa², Daniel Sergelidis⁴

¹Aristotle University of Thessaloniki, Laboratory of Hygiene of Foods of Animal Origin-Veterinary Public Health, School of Veterinary Medicine, Thessaloniki, Greece, ²Sciensano, Ixelles, Belgium, ³Aristotle University of Thessaloniki, Department of Microbiology and Infectious Diseases, School of Veterinary Medicine, Thessaloniki, Greece, ⁴Aristotle University of Thessaloniki, Laboratory of Safety and Quality of Milk and Dairy Products, School of Veterinary Medicine, Thessaloniki, Greece, ⁵Greek Agricultural Organization–DIMITRA, Veterinary Research Institute of Thessaloniki, Thermi, Greece, ⁶Aristotle University of Thessaloniki, Department of Microbiology, Medical School, Thessaloniki, Greece

Background: Methicillin-Resistant S. aureus (MRSA) represent a serious public-health concern due to their ability to colonize and infect both humans and animals. The handling and consumption of animal origin-food contaminated with MRSA could lead to the pathogen transmission to humans. MRSA are increasingly isolated from lactating ruminants, milk and dairy products.

Materials/methods: A total of 1059 samples [farmers: 109, cows: 124, sheep: 215, goats: 123, raw milk: 96, food handlers: 87, dairy products: 93, equipment 212] from 6 dairy plants and the associated 64 dairy farms were collected from three geographical regions of North Greece (Epirus, Central Macedonia, and East Macedonia and Thrace). All phenotypically and molecularly confirmed MRSA strains were characterized for the presence of selected virulence factors such as staphylococcal enterotoxins (sea-see) and Panton-Valentine Leucocidin (PVL) genes and their ability to produce biofilms. Finally, the genetic variability of the MRSA isolates and the presence of epidemiological clones were assessed via Pulsed-Field Gel Electrophoresis (PFGE) and spa typing.

Results: MRSA were isolated from 38/1059 (3.6%) samples: 16/196 (8.2%) from employees-farmers, 9/462 (1.9%) from animals, 4/189 (2.1%) from dairy products and 9/212 (4.2%) from dairy plants’ equipment. All isolates were able to produce biofilms and 94.7% of them carried one or more enterotoxin-coding genes, with the sec being the most prevalent. The pvl gene was not detected. Sixteen spa types were identified among the MRSA isolates, with t127 being the most prevalent 14/38 (36.8%) indicating that it represents the predominant LA-MRSA type in Greece. Furthermore, spa type t034 (CC398) was isolated for the first time from livestock (goat) in Greece. PFGE typing of MRSA isolates revealed the presence of epidemiological clones in the dairy production chain, even within the dairy plants’ facilities.

Conclusions: Our study’s findings suggest that the dairy production chain may contribute to the dissemination of MRSA in the community and highlight the need for continuous monitoring of the dairy production chain and re-evaluation of the implemented cleaning and sanitizing programs, as well as the adoption of preventive strategies along the dairy production chain in order to minimize public-health risks.

**Viral aetiology and epidemiology of acute paediatric gastroenteritis in southern region of Saudi Arabia with Yemen borders**

Abdelwahid Babiker*1, Mohamed Hassan2, Ahmed Al-Hakami1, Abdullah Algahtani2

1College of Medicine, King Khalid University, Abha, Saudi Arabia, 2College of Applied Medical Sciences, Najran University, Najran, Saudi Arabia

**Background:** Diarrheal diseases remain the second most important cause of death in children under five years worldwide. Globally, it had been estimated that about 1.7 billion cases of pediatric gastroenteritis occurring annually. Rotaviruses were known as the leading cause of severe gastroenteritis in children in developed and developing countries. Adenoviruses recognized as the second common agent, after rotavirus, responsible for viral diarrhea in children younger than 2 years. Astroviruses had also confirmed as potential causes of viral gastroenteritis accounting for 5-9% in children. In the tropical regions, the prevalence of these infections was observed higher during the rainy seasons. In Saudi Arabia (KSA), there had been few studies addressing the occurrence and prevalence of pediatric viral diarrheal infections in some regions of the country. However, this is the first study which focuses on the distribution and magnitudes of pediatric viral gastroenteritis in the southern region of Saudi Arabia near the borders with Yemen.

**Materials/methods:** 461 diarrheal samples collected randomly from the hospital-admitted children under five years of age in the southern region of KSA. Immunochromatographic technique (ICT) was employed to investigate the presence of rotaviral, adenoviral and astroviral antigens in these samples. The prevalence rates for each virus type was calculated. The dual (coinfection) rates, sex and age distribution of these viral infections were also assessed.

**Results:** Out of the 461 specimens, 85 (18.4%) were noted positive for at least one virus. Among the 85 positive specimens, 104 viruses were detected with the frequency of 72 (69.2%), 25 (24.0%) and 7 (6.7%) for rotavirus, adenovirus and astrovirus respectively. 19 cases (22.4%) revealed dual viral infections (co-infections) (Table 1).

**Conclusions:** Rotaviruses detected as the most common cause of acute gastroenteritis in children in the study area, followed by adenoviruses and astroviruses. ICT confirmed and suggested as a rapid, sensitive and routine serological test for detection of diarrheal viruses among pediatric patients.

Abstract 4505

Invasive pneumococcal disease in the Comunidad Valenciana, Spain, 2011-2019

Marta Garrido Jareño1, Ana Gil Brusola2, Noelia Lozano Rodríguez2, Díana Sabalza2, Juan Frasquet2, Jose Luis López-Hontangas2

1Drug Discovery Unit, Health Research Institute Hospital La Fe, Valencia, Spain, 2Microbiology department, La Fe University Hospital, Valencia, Spain

Background: Complicated disease due to Streptococcus pneumoniae is a fact in many geographical areas. In the Comunidad Valenciana (CV), Spain, invasive pneumococcal disease (IPD) is a mandatory reportable disease since 2007. The aim of this study was to describe the epidemiology and serotype distribution of the S. pneumoniae isolates causing IPD in children and adults in the CV between January 2011 and mid-November 2018.

Materials/methods: Retrospective study of IPD reported to the Public Health Department between January 2011 and September 2019. Epidemiological data from cases was obtained from the Microbiology Surveillance Network of the CV (RedMIVA). Serotyping of culture confirmed cases was done using the slide agglutination test (Denka Seiken, Tokyo, Japan) and the modified Quellung test (Statens Serum Institute) at the Microbiology Department of the University Hospital La Fe.

Results: A total of 3,368 cases of IPD were reported between 2011-2018 period in the CV – 408 in 2011, 395 in 2012, 374 in 2013, 360 in 2014, 373 in 2015, 374 in 2016, 466 in 2017 and 618 in 2018. In 2019, 287 strains of IPD have been serotyped until September. A total of 2591 strains were serotyped – 282 in 2011, 293 in 2012, 309 in 2013, 300 in 2014, 298 in 2015, 302 in 2016, 339 in 2017, 468 in 2018 and 287 until September 2019. Of the total of patients, 59.13% were men, 7.96% were less than 5 years old and 53.32% over 65 years old – 161/287 (50.09%) this last year. Figure 1 shows IPD mucous serotype distribution expressed in percentage with respect to total IPD cases (2011-2018). In 2019 the percentage was done with respect to total serotyped.

Conclusions: The incidence of mucous serotypes causing IPD has increased in the CV in recent years. Serotypes 3 and 8, both mucous, account for one third of IPD cases and the latter serotype presents as an emergent serotype that should be included in new vaccines.

Abstract 4507

**Endotoxin activity assay as a better predictor for septic shock in critically ill cirrhotic patients**

Vikas Khillan*, Preeti Badhan1, Rakhi Maiwall1, Pratibha Kale1

1Institute of Liver and Biliary Sciences, New Delhi, India

**Abstract third-party references:** Institute of liver and biliary sciences

**Background:** Early detection remains the mainstay for improving outcomes in sepsis. Various biomarkers like procalcitonin (PCT), C-reactive protein (CRP) are available but these have limited role to play in patients with liver disease. Recently the role of Endotoxin activity is being assessed as a biomarker for sepsis in patients with cirrhosis. Hence, this study was taken up to assess the role of endotoxin activity assay (EAA) as a biomarker and to compare its activity with procalcitonin in prediction of septic shock in critically ill cirrhotic patients admitted to the intensive care unit.

**Materials/methods:** Endotoxin activity and PCT were determined, using the principle of chemiluminescence [according to manufacturer's guidelines], on the day of admission and Day-3. These values were correlated with clinical severity scores and laboratory parameters like total leukocyte count, differential leukocyte count, lactate levels, blood pH and cultures sensitivity results. Statistical analysis using Kaplan Meier survival curves was done.

**Results:** 70 critically ill cirrhotic patients admitted to ICU were enrolled. Baseline characteristics showed mean age of 45.1±4.4years, with a median MELD 35(25-40), SOFA 10(8-11), EAA 0.57(0.40-0.75) and PCT 1.23(0.66-2.79). Cultures were positive in 37 patients. Gram negative isolates (83.8%) predominated with *Klebsiella pneumoniae* (54.83%) being the most common organism. 2/3rd of patients progressed into severe sepsis or septic shock and showed high levels of EAA (p=0.001) while levels of PCT (p>0.6) did not correlate with the severity of the disease. Comparative analysis of EAA and PCT as a predictor of septic shock showed an area under ROC curve for EAA (0.778) to be statistically significant compared to PCT(0.551) which was not significant. High levels of EAA on admission were associated with an increased 28day mortality rate (57%).

**Conclusions:** EAA is a better biomarker and predictor of severe sepsis and septic shock in critically ill cirrhotic patients compared to procalcitonin. High levels of EAA on admission are associated with increased morbidity and mortality.

**Detection and successful containment of a NDM-1-producing Proteus mirabilis clone spread in an Italian sub-acute care unit**

Alessandra Mercato*1, Ibrahim Bitar2, Vittoria Mattioni Marchetti2, Federica Marchesini1, Marika Mancinelli2, Silvia Bracco1, Vanina Rognoni3, Adriano Anesi3, Elisabetta Nucleo1, Roberta Migliavacca1

1University of Pavia, Unit of Microbiology and Clinical Microbiology, Department of Clinical-Surgical, Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy, 2Faculty of Medicine, Biomedical Center, Charles University, Pilsen, Pilsen, Czech Republic, 3'Ospedale Maggiore di Lodi', Laboratory of Microbiology, Lodi, Italy

**Background:** Aim of the study was to report an experience of prompt detection and containment of a blaNDM-positive *P. mirabilis* (Pm-NDM) clone, emerged among inpatient at “S. Angelo Lodigiano” Hospital (LO), Northern Italy.

**Materials/methods:** In April 2019, n=4 *P. mirabilis* strains were selected on CHROMagar™ CPE (BD) at Lodi Hospital Clinical Microbiology Laboratory from two infected/colonized inpatients at the Sub-Acute Care Unit of “S. Angelo Lodigiano” Hospital. Xpert-Carba-R System (Cepheid) detected *blaNDM*-type determinant. Thirty samples were obtained from room surfaces and patients’ skin using SRK Hygiene monitoring kit system (Copan), in order to assess the extent of environmental contamination and with containment purposes. Species identification and susceptibility tests were performed by Vitek-2 System (BioMérieux) and AutoScan4 System (Beckman Coulter). Susceptibility results were interpreted according to EUCAST 2019 guidelines. Microarray Check-MDR CT103XL (Checkpoints), PCR and sequencing were used for beta-lactamases genes screening and *blaNDM*-type identification. Molecular typing was accomplished by PFGE (SfiI) (BioRad). Whole Genome Sequencing (WGS) by Illumina MiSeq was carried out on CRE1 strain from urine sample, as representative.

**Results:** A total of eight Pm-NDM strains were collected from urine (n=2), rectal (n=2), skin swabs (n=2) of two inpatients and environmental swabs (n=2/30), resulted susceptible only to aztreonam, gentamicin and amikacin. The i) rapid *blaNDM*-positive *P. mirabilis* identification by phenotypic/molecular methods, ii) patients cohorting, iii) infection control measures undertaken (i.e. environmental sampling) and iv) room disinfection by a dry mist of 12% hydrogen peroxide, allowed the resolution of Pm-NDM spread within a month. Microarray, PCR and sequencing assays confirmed a *blaNDM*-1 gene variant. PFGE showed the presence of a unique profile. According to WGS, CRE1 Pm-NDM harbored a larger 99278bp plasmid codifying resistance to sulphonamide (*sul1*), trimethoprim (*dfrA14*), tetracycline (*tet(B)*), rifampicin (*arr-2*), aminoglycosides (*aadA1, aph(3')-VI*), beta-lactams (*blaOXA-10, blaNDM-1*), and a small 2555bp plasmid responsible for quinolone resistance (*qnrD1*).

**Conclusions:** This is the first report on the detection/rapid containment of a MDR Pm-NDM-1 clone emerged in a Northern Italy Hospital. The findings highlight the importance of the screening for *P. mirabilis* NDM-producer, an emerging threat in Italian area.

**Effect of antiviral therapy against hepatitis C virus on gut microbiota**

Biagio Pinchera*1, Riccardo Scotto1, Emanuela Zappulo1, Antonio Riccardo Buonomo1, Alberto Enrico Maraolo1, Nicola Schiano Moriello1, Flavia Gison2, Francesca De Filippis2, Danilo Ercolini2, Ivan Gentile1

1University of Naples "Federico II", Department of Clinical Medicine and Surgery, Section of Infectious Diseases, Naples, Italy, 1University of Naples "Federico II", Department of Agricultural Sciences, Division of Microbiology, Portici, Italy

**Background:** The intestinal microbiota plays a fundamental role in physiological homeostasis and in human pathology. No study has assessed the change in gut microbiota after treatment with direct antiviral agents in patients with Hepatitis C Virus (HCV) infection. The aim of the study was to evaluate the effects of such therapy on microbiota.

**Materials/methods:** We enrolled patients with HCV-related chronic liver disease attending the Infectious Diseases Unit of the A.O.U. Federico II of Naples, from January 2017 to March 2018, treated with DAAs. Fibrosis was evaluated by the mean of Fibroscan®. For each patient, a fecal sample was collected before therapy and by SVR12 time. The fecal microbial DNA was extracted using the standard operating procedures of the IHMC. The amplicons were then normalized, combined and sequenced with the Illumina MiSeq system. Intra-sample or α-diversity was evaluated through rarefaction curves obtained with different and specific metrics. Patients who received antibiotics in the last 6 months were excluded.

**Results:** We enrolled twelve patients (6 male, 8 genotype 1 (1 subtype 1a), 4 genotype 2). Fibrosis score was F0 in 1 patient, F2 in 1 patient, F3 in 4 patients and cirrhosis in the remaining 6 (all in Child-Pugh class A). All patients received DAAs for 12 weeks (5 with Paritaprevir-Ombitasvir-Ritonavir-Dasabuvir, 3 with Sofosbuvir-Ledipasvir, 1 with Sofosbuvir-Ribavirin, 1 with Sofosbuvir-Daclatasvir, 2 with Sofosbuvir-Velpatasvir) and all achieved SVR12. In all patients, we observed a reduction of potentially pathogenic microorganisms (i.e. Enterobacteriaceae), and a shift towards a more heterogeneous and less harmful bacterial population [Figure 1]. Furthermore, a trend of increase in α-diversity was observed in patients by SVR12 compared to baseline time. This trend was markedly more evident in patients without liver cirrhosis than in those with cirrhosis.

**Conclusions:** Our study shows that viral eradication obtained with DAA is associated with a trend in restoring the heterogeneity of α-diversity and in reducing the percentage of potentially pathogenic gut microbiota species, although this benefit is less evident in patients with cirrhosis. Further studies with larger sample size are necessary to confirm these data.

Epidemiology of ESBL-producing Enterobacteriaceae among healthcare students, Portuguese Red Cross Health School of Lisbon, Portugal

Claudine Fournier1,2*, Marta Aires De Sousa2, Begona Fuster1, Patrice Nordmann1, Laurent Poirel1

1University of Fribourg, Fribourg, Switzerland, 2ESSCRP, Lisbon, Portugal

Background: The aim of the present study was to prospectively evaluate the prevalence of intestinal carriage by ESBL-producing Enterobacteriaceae among Portuguese students attending health care bachelors, and to determine the epidemiology and antimicrobial resistance of ESBL-producing isolates.

Materials/methods: One-hundred and eleven fecal samples recovered from Portuguese health care students were screened for either ESBL-producing, carbapenem-, colistin-, or pan-aminoglycosides-resistant Enterobacteriaceae, using respective screening media. All recovered isolates were tested for antimicrobial susceptibility and characterized by pulsed-field gel electrophoresis (PFGE) and multilocus sequence typing (MLST). Plasmid analysis was completed by plasmid-based replicon typing (PBRT). The corresponding resistance mechanisms were searched by PCR followed by sequencing.

Results: A total of 17 ESBL-positive Enterobacteriaceae (16 Escherichia coli and a single Klebsiella pneumoniae) were recovered from 16 patients, corresponding to a prevalence of 14.5%. The E. coli isolates were distributed into seven PFGE types and three sequence types (ST). The most common ESBL identified was CTX-M-1 (n=13; 76%), followed by CTX-M-15 (n=3; 18%), and CTX-M-8 (n=1; 6%). The only ESBL-K. pneumoniae carried a blaCTX-M-15 gene. The majority of the strains were resistant to sulfamides (88%), trimethoprim-sulfamethoxazole (82%), fosfomycin, and tetracycline (71%), and a few to tobramycin and kanamycin (12%). PBRT revealed four different plasmid types: IncFIA/FIB (n=13), IncFIC (n=2), IncI2 (n=1), and IncP (n=1). A major clone, ST10-blaCTX-M-1, included 12 E. coli isolates. The blaCTX-M-1 gene was located onto an IncFIA/FIB plasmid type with a size of 56 kb, which co-harbored genes encoding resistance to tetracycline, sulfamides, trimethoprim-sulfamethoxazole, and fosfomycin. Such lineage had been previously identified among pigs in Portugal, however PFGE analysis showed that human and animal isolates were not clonally related.

Conclusions: We found a high prevalence of fecal carriage of ESBL-producing E. coli among healthy health care students in Portugal, underlying this population as an important reservoir.

Abstract 4511

Assessment the immunogenicity of UpaH autotransporter of uropathogenic Escherichia coli isolates admixed with vitamin D as a novel vaccine candidate against urinary tract infection

Mohammad Reza Asadi Karam1, Mehri Habibi1, Saba Azimi1, Saeid Bouzari1

1Pasteur Institute of Iran, Tehran, Iran

Background: Urinary tract infections (UTIs) caused by Uropathogenic Escherichia coli (UPEC) are among the most common infection diseases worldwide. Furthermore, increasing rate of antibiotic resistance among the isolates will make treatment of these infections ever more complicated and costly in the future. Therefore, there is a need for designing of an efficacious vaccine against UTI. UPEC has several types of autotransporter proteins such as UpaH that play important roles in pathogenesis. Thus, UpaH could be an ideal target against UTIs. In this study, we analyzed the UpaH of UPEC by in silico studies, and then the selected fragments were expressed and purified. Finally, the immunogenicity of the designed construct was evaluated in mice model.

Materials/methods: In this study, UpaH sequence of UPEC strains was evaluated by bioinformatics studies. The UpaH was expressed in BL21 host and purified by nickel resins. The analysis of the purified protein was performed by SDS-PAGE and Western blot. LPS level of the protein was removed by Triton-X114. Balb/C mice were subcutaneously vaccinated three times with UpaH alone and admixed with vitamin D. Then, serum and urine samples were obtained from the mice on days 0 and 42 for measurement the anti-UpaH IgG and IgA immune responses by ELISA method.

Results: According to the bioinformatics results, the best domains of UpaH were selected. Analysis of purified UpaH by SDS-PAGE and Western blot showed bands 32 KDa. Mice vaccinated with UpaH alone induced significantly higher humoral immune responses in serum and urine (IgG and IgA) than the control mice (P<0.05). Furthermore, vitamin D could increase the levels of IgG in serum and urine of the vaccinated mice.

Conclusions: Our results suggest that UpaH protein of UPEC has the potential of an ideal candidate against UTIs. We observed that vitamin D tended to direct the immune responses towards both the Th1 and Th2 responses. This could be valuable in eradication of intracellular and extracellular reservoirs of UPEC. Thus, vitamin D can be considered as a safe and effective adjuvant in designing of a vaccine against UTIs. Assaying the protection efficacy of the vaccine candidate is under progress.

Abstract 4512

Evaluation of commercial multiplex real-time PCR panels to detect bacterial, parasite and viral gastrointestinal pathogens in clinical specimens

Paul Bird*, Christopher Holmes

1Clinical Microbiology, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

Abstract third-party references: University Hospitals of Leicester, Mobidiag

Background: Gastrointestinal infections are often non-specific in symptoms and can be caused by a multitude of organisms with the potential to cause outbreaks, particularly in healthcare facilities. High throughput detection methods which can identify a broad range of pathogens are of use to clinical microbiology departments for pathogen screening. The aims of this evaluation was to compare the performance Mobidiag Amplidiag Easy Bacterial, Viral, and Parasitic PCR Panels against current routine methods, including culture, antigen detection and microscopy and to assess the ease of use of the Amplidiag workflow.

Materials/methods: Two hundred and seventy one non-consecutive stool samples were tested retrospectively on the Amplidiag system for the presence of 18 pathogens. This included 105 bacterial, 120 parasitic, and 112 viral tests. Samples were inoculated in eNat tubes (Copan) before automated extraction, PCR setup, real-time PCR amplification and result interpretation using the Amplidiag Easy workflow. Results were compared to standard-of-care testing using culture, EIA or immunochromatographic lateral flow devices, as appropriate to the target pathogen.

Results: The assay demonstrated overall sensitivity and specificity of 70.6% and 98.3% respectively for the bacterial panel, 86.7% and 99.0% for the parasite panel, and 73.3% and 97.7% for the viral panel. Amplidiag gave false-negative results for four each of Salmonella spp. and Giardia lamblia, two Rotavirus, and one each of Campylobacter sp., Norovirus GII and Adenovirus. An additional 49 pathogens were detected by Amplidiag in 32 (11.8%) specimens. No instrument failures were recorded, reproducibility was within acceptable levels (<10% CoV) and all results were obtained in under 3.5 hours.

Conclusions: Specificity across all panels was high, demonstrating the ability of the Amplidiag to give adequate negative predictive values for screening. For the bacterial panel, failure to detect Salmonella spp. cultured following selenite broth enrichment was the primary cause of low sensitivity. For other assays, low numbers of positive samples in this study impacted the sensitivity analysis. The application of the single, simple Amplidiag Easy workflow covering a broader range of pathogens and improved diagnostic yield compared to routine methods make this system an attractive option as a primary screening method in diagnostic clinical microbiology laboratories.

Abstract 4513

Diversity of ESBL- and carbapenemase-producing Enterobacteriaceae with emergence of mcr-1 and carbapenem transferable resistance in a cancer clinical setting in Egypt

Mai Muhammed Mersal1*, Josman Palmeira1, Helena Maria Neto Ferreira1

1University of Porto - Faculty of Pharmacy, Porto, Portugal

Background: Carbapenem and colistin resistant Enterobacteriaceae in the Middle East represents a severe threat. The present work studied resistance spread at an oncological hospital in Egypt.

Materials/methods: Between 2016 and 2017, 130 MDR and XDR Enterobacteriaceae isolates from hospitalized cancer patients at National-Cancer-Institute-Cairo-University were detected. Carbapenemase and ESBL phenotypic detection was complemented by PCR to carbapenemases, CTX-M ESBL, qnr, AAC(6’)-Ib-cr and mcr-1. Conjugation and typing by PFGE & MLST were also performed.

Results: In 81 K.pneumoniae and 49 E.coli, 61.8% were positive at least for one of carbapenemase detection tests (Modified-Hodge, Blue-CARBA and CIM). ESBL was detected in 37.7%. OXA-48, NDM-1 and IMP-1 were detected in 36.2%, 20.8%, 0.01% respectively, highlighting, 12.3% of isolates co-produced OXA-48 and NDM-1, while 32.4% co-produced CTX-M and OXA-48.

High percentage (67.6%) harboured CTX-M genes, being 73.9% of CTX-M-Group-1 (58.8% were CTX-M-15) and 39.1% of Group-9 including 30.4% with both genes.

Expression of qnrB(9%), qnrS(14.7%) and Aac(6’)-Ib-cr(20.6%) and cross resistance in 20.6% producing OXA-48, CTX-M and fluoroquinolone-resistance-genes (57.1% qnrS and 71.4% aac(6’)-Ib-cr).

Two ESBL-producing E.coli co-expressed mcr-1, CTX-M-15, CTX-M-GP9, one of them co-expressed qnrS and Aac(6’)-Ib-cr. Successful conjugation transfer in 11.5% showed carbapenemase and CTX-M expression (46.7% carbapenemase, 66.7% CTX-M, 20% showed carbapenemase and CTX-M co-expression). PFGE showed clonal diversity for K.pneumoniae and E.coli isolates, with similar carbapenemases and/or CTX-M present in different clusters. K.pneumoniae MLST revealed 60% clustering in three carbapenemase-producing high-risk clones [ST101 (32%), ST383 (16%) and ST147 (12%)]. High-risk ST11, ST16 were detected in 8% while high-risk ST22, ST37 were detected in 4%.

Conclusions: High prevalence of ESBL-producing isolates with carbapenem and colistin resistance emergence is reported. Mcr-1 co-expression with CTX-M-15, CTX-M (GP9), qnrS and Aac(6’)-Ib-cr in ESBL-producing E.coli showing carbapenemase and CTX-M conjugal transfer what represents a big alert of XDR bacteria spread. This is calling for alternative treatment for Enterobacteriaceae infections and infection control precautions.

Abstract 4516

Validation of a measles virus detection assay for early clinical management

Stephanie Haim-Boukobza1*, Eric Hedbaut1, Virginie Dubois1, Nesrine Day2, Jean Dominique Poveda2

1Laboratoire Cerba, Saint-Ouen-l’Aumône, France, 2Laboratoire Cerba, Saint-Ouen-l’Aumône, France

Background: Since the end of 2017, a significant increase in measles cases was observed worldwide and in Europe. Early management (vaccination or immunoglobulins administration) requires viral genome detection by RT-PCR in salivary, nasopharyngeal, respiratory or blood samples. The objective of this work was to evaluate a CEIVD kit (FTD Measles).

Materials/methods: Several approaches were performed to assess for analytical performances. First, a 10⁷ copies/ml quantified control (Amplirun Measles RNA Control, CEIVD Vircell) was used for repeatability (n = 16), reproducibility (n=8), and sensitivity by using a method of successive dilutions (10⁻¹ to 10⁻⁷). Second, a diluted MMR vaccine was tested to assess genotype A detection. Then, 29 serum samples already characterized in Measles serology (patients at the beginning of the eruptive phase) with IgM>5 and negative IgG (LIAISON XL, Diasorin) were tested by using FTD Measles assay. Finally, 20 samples were provided by the Measle French National Reference (MFNR): different types of sample (salivary and pharyngeal sample), and viral strains: A, B3, or D8, and compared between both techniques: MFNR RT-PCR vs. FTD RT-PCR. Assays were performed by using a CFX96 device.

Results: Repeatability (mean CT=28.15) and reproducibility (mean CT=28.41) showed coefficients of variation (CV%) of 1.1% and 1.4%, respectively. At the lower dilution value (1,4 cp/μl), the four replicates remained detectable with equivalent CTs (CT=36.24, CT2=37.04, CT3=36.74, CT4=38.42; CV%=2.5%). Similarly, the MMR vaccine (genotype A) tested was well amplified (CT=22.56). Of the 29 patients with IgM+/IgG- serology for whom a positive viral load was expected a positivity was indeed observed by RT-PCR in all serum tested (CT from 31.25 to 38.72). Finally, the 20 samples of patients tested in the CNR technique and in the FTD technique were all found to be positive and had equivalent CTs (CT from 15.47 to 27.96). The observed virus level were lower in serum than in salivary and pharyngeal sample, as expected.

Conclusions: The FTD Measles technique presented satisfactory analytical performances and its use is validated for the main circulating strains in France and Europe, allowing an early patient management.

Background: Pseudomonas aeruginosa [P aeruginosa] bacteremia is a severe clinical condition and is associated with high mortality rates. There is no agreement on the optimal antibiotic regimen for the treatment of P aeruginosa bacteremia. One of the most controversial questions is the use of combination vs. monotherapy as a definitive antibiotic treatment. We aimed to evaluate the impact of these two options in hospitalized patients with P aeruginosa bacteremia on 30-day mortality.

Materials/methods: This was a multinational, multicenter retrospective study conducted in 9 countries [25 hospitals] across Europe, Australia and Israel. Adult patients hospitalized with P aeruginosa bacteremia during the years 2009-2015 were included. The main outcome was all-cause 30-day mortality. Propensity score weighting was used to balance covariates between the treatment groups; Generalized Estimating Equation model was constructed to control for center as a random effect.

Results: We analyzed 1383 patients. Among the study cohort, 28% [392/1383] received two active antipseudomonal agents concomitantly and 72% [991/1383] received a single active agent as definitive therapy. Patients treated with combination therapy were significantly younger [median 63 years [interquartile range [IQR] 51-74] vs 68 years [IQR 57-78]]. Combination group patients were more likely to have neutropenia, baseline malignancy, and a vascular catheter at presentation. The overall 30-day mortality rate was 17.6% [244/1139]. Combination therapy was not associated with reduced 30-day mortality in both univariable and multivariable propensity adjusted analyses [OR 0.86, 95% CI 0.61-1.21]. Combination therapy group had a significantly longer length of hospital stay [16 days [IQR 10.7-27] vs 14 days [IQR 9-28], P=0.027]. Moreover, patients who received combination treatment were more prone to antibiotic adverse event [rash], [5.7% [22/383] vs 2.3% [22/940], p=0.002]. Development of resistance among subsequent P aeruginosa isolates was without significant difference between groups [combination 54/ 392 [14%], monotherapy 124/991 [13%], p=0.602].
Conclusions: In this large multicenter study, we found no significant mortality benefit for combination therapy in the treatment of *P. aeruginosa* bacteremia. Prospective studies are needed to refine clinical management and to avoid unnecessary antibiotic treatment and drug-related adverse events.

Investigating dynamic protein binding of clindamycin in vivo by means of intravasal microdialysis in healthy volunteers

Beatrix Wulkersdorfer1*, Sebastian Wicha2, Elizaveta Kurdina1, Peter Matzneller1, Valentin Al Jalali1, Matthias Vossen1, Sonja Riesenhuber1, Edith Lackner1, Christoph Born1, Frieder Kees1, Markus Zeitlinger1

1Medical University of Vienna, Wien, Austria, 2University of Hamburg, Dept. of Clinical Pharmacy, Institute of Pharmacy, Hamburg, Germany, 3University of Regensburg, Regensburg, Germany

Background: Clindamycin (CLI), a lincosamide antibiotic, is a commonly used antibiotic, in particular in patients with anaerobic bacterial infections. In addition to pharmacokinetic (PK) properties, protein binding (PB) plays a crucial role in unfolding the full antiinfective effect of antibiotics in vivo. Recently, doubt has been raised that in vitro methods like ultrafiltration can capture the dynamic and concentration depending PB of highly bound antibiotics. The following study set out to determine the PK profile, bound and unbound drug concentrations versus time profile of clindamycin in healthy subjects by means of in vivo microdialysis.

Materials/methods: Six healthy volunteers received a single i.v. infusion of CLI 900 mg, applied over 30 minutes. Antibiotic plasma concentrations were measured for up to 8 hours after drug administration. Simultaneously, unbound CLI concentrations were obtained by means of in vivo intravasal microdialysis (MD) or in vitro ultrafiltration at defined time points for up to 8 hours post dosing. CLI was assayed in plasma and MD fluid using a validated HPLC-MS/MS method. Non-linear mixed effects modelling in NONMEM® was used to quantify the PB in vivo and in vitro.

Results: Cmax was 14.95, 3.39 and 2.32 µg/ml and AUC0-inf was 41.78, 5.8 and 6.14 µg/ml*h for plasma, ultrafiltrate und microdialysate, respectively. Calculated ratio of AUCunbound/AUCtotal showed similar values of 13.9±1.8% and 14.7±3.1% for ultrafiltration and microdialysate, respectively. However, protein binding was a dynamic and concentration dependent process in vitro and in vivo. Modelling confirmed the non-linear, saturable protein binding for CLI with significantly different dissociation constants (Kd) for the alpha-1 acid glycoprotein (AAG)-CLI complex in median (CI95%) of 3.25 µM (3.1-3.41) in vitro vs. 1.16 µM (1.1-1.21) in vivo (figure 1). Moreover, the estimated number of binding sites per AAG molecule was 2.33 (2.27-10.6) in vitro vs. 1.55 in vivo (1.49-1.57).

Conclusions: Significantly different protein binding was observed in in vitro ultrafiltration vs. in vivo intravasal MD with a tendency to over-estimate the protein binding in vitro, in particular in the distribution phase.

Figure 1. Visual predictive check of the developed pharmacometric model for the matrices plasma (left), ultrafiltration (middle) and microdialysate (right).

Abstract 4521

Evaluation of a dual therapy and a simplified, patient-centred monitoring strategy for the long-term management of HIV infection: a non-inferiority, randomised, controlled, open-label clinical trial (SIMPL'HIV)

Delphine Sculier¹, Marinosci Annalisa*¹², Gilles Wandeler¹, Marcel Stöckle¹, Enos Bernasconi¹, Dominique Braun⁵, Pietro Vernazza¹, Matthias Cavassini¹², Karin Metzner³, Laurent Arthur Decosterd³, Marta Buzz⁷, Huldrych Gunthard⁶, Patrick Schmid⁸, Sabine Yerly¹, Andreas Limacher², Matthias Egger⁹, Alexandra Calmy¹

¹Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland, ²Hôpitaux Universitaire de Genève, Genève, Switzerland, ³Inselspital, Bern, Switzerland, ⁴University Hospital of Basel, Basel, Switzerland, ⁵EDC Ospedale Regionale di Lugano - Civico, Lugano, Switzerland, ⁶University Hospital of Zürich, Zürich, Switzerland, ⁷Kantonsspital St.Gallen, St. Gallen, Switzerland, ⁸Lausanne University Hospital, Lausanne, Switzerland, ⁹Clinical Trials Unit, Bern, Switzerland

Background: Simplification of combination antiretroviral therapy (cART) has been studied to reduce pill burden and improve quality of life in HIV patients, while minimizing costs and potential toxicity. It also includes optimized monitoring and decentralization of health care.

Materials/methods: SIMPL'HIV is a multicentre, factorial, non-inferiority randomized trial conducted among experienced HIV-infected adults in Switzerland. Participants were randomized 1:1:1:1 to switching to dolutegravir (DTG) + emtricitabine (FTC) or to continuing cART, and to patient-centred monitoring, defined as annual immunological and safety monitoring vs continuation of 3-monthly surveillance. Patient-centred monitoring included telephone calls, medication delivered by mail, and decentralized venepuncture. Quality of life was assessed using the PROQOL-HIV questionnaire, consisting of 43 questions on a scale of 1 to 5 points. The total score was standardized on a 100-point scale. We previously demonstrated non-inferiority [non-inferiority margin: -12%] of the dual therapy arm compared to cART by maintaining HIV-RNA below 100 copies through 48 weeks. This analysis presents efficacy, safety and quality of life data by treatment and monitoring groups.

Results: Forty-eight participants were randomized to DTG/FTC+ patient-centred monitoring, 45 to DTG/FTC+ 3-monthly surveillance, 47 to cART+ patient-centred monitoring, and 47 to cART+ 3-monthly surveillance. Mean nadir CD4 count was 259 cells/mm³ [SD 187]; 17% were female. In the intention-to-treat analysis, the proportion of patients with HIV-RNA <100 copies/mL throughout 48 weeks was similar in the four groups [Table 1]. The overall proportion of adverse events and discontinuations did not differ by randomization arm. Quality of life was rated above 80 points in all arms and was statistically superior in the DTG+FTC compared to the cART arm.

Conclusions: DTG+FTC was non-inferior to cART as maintenance therapy and a simplified, patient-centred monitoring approach did not affect viral suppression in this nationwide clinical trial. Quality of life was improved in dual therapy compared to cART at week 48.

Abstract 4522

High-throughput genome sequencing highlights Pseudomonas aeruginosa adaptative evolution in the urinary tract

Background: Pseudomonas aeruginosa (PA) is an opportunistic pathogen, associated with persistent urinary tract infections or asymptomatic bacteriuria. While adaptative evolution of PA in cystic fibrosis patients is well studied, little is known about the behaviour of PA in the urinary tract. In this context, the objective was to describe molecular diversity of sequential PA urinary isolates collected in 7 inpatients over a 27-months period.

Materials/methods: 101 PA isolates (up to 5 per sample) were collected from 22 urines and sequenced using a NextSeq 500 sequencing system (Illumina Inc.). At least 50X coverage was provided to ensure a good quality sequence. MultiLocus Sequence Typing (MLST) was performed using Center for Genomic Epidemiology database. Phylogenetic analyses were performed using ParSNP software. Clone types (defined as less than 6000 SNPs between 2 isolates) were defined using Snippy software. Genomic annotation was performed using Prokka software.

Results: The average number of contigs per genome was 85 [46-123]. Draft genomes ranged in size from 6.3 to 7.1 Mbp with a mean G+C content of 66%. Alignment of the 101 core genomes (draft assemblies) led to the definition of 6 clusters in congruence with the 6 sequence types [ST] identified. All isolates from a single patient belonged to the same ST within a given urine sample but also over time; only 2 patients had isolates with the same ST. Interestingly, the genome size of isolates of 3 patients decreased over time. These loss events affected genes involved in acute virulence, metabolic pathways, regulation (mainly two component systems), or transport of small molecules.

Conclusions: Our data highlight that even if patients are colonized or infected with a single PA clone, adaptative evolution of isolates is observed within the urinary tract. This evolution could be associated with loss events rather than gene acquisition. Further analysis of genes for which single nucleotide polymorphisms appeared over time is in progress. To our knowledge, this is the first genomic study on adaptative evolution of PA urinary isolates collected from a given urine sample and over time.

Cunha also acknowledges FCT for the IF/01616/2015 contract.

Background: Environmental health is increasingly compromised by persistent toxic substances, which may have serious implications in food safety and, thus, in human health. Polybrominated diphenyl ethers (PBDEs) are anthropogenic contaminants with endocrine disruption abilities, which have been commonly found in food. Growing evidence points out that the human gut microbiota interacts with xenobiotics, which may lead to the impairment of host homeostasis if functions of microbiota become compromised. The aim of this study was to ascertain if the physiological balance of human gut microbiome is affected by the presence and dose of exposure to PBDEs.

Materials/methods: Fermentation was performed in a batch closed-system using an inoculum made from fresh human stool. Diluted fecal inoculum was incubated (i) with PBDEs at three concentrations or (ii) without PBDEs. Enumeration of the fecal microbiota was carried out using the standard serial dilution method in buffered peptone water on the appropriate culture media. Mesophilic, Gram-negative bacteria and coliforms were quantified by classic plating methods. Changes in the gut microbiome were evaluated after DNA extraction followed by deep sequencing of the 16S rDNA V3-V4 region.

Results: The exposure to PBDEs resulted in significant statistical differences (p < 0.05) between groups, showing that “Intermediate” and “High” exposure levels reduce overall bacterial density in comparison to “Low” exposure levels. Considering Gram-negative bacteria and total coliforms, no statistically significant (p > 0.05) differences were confirmed between groups. Nevertheless, all test groups showed lower bacterial densities in comparison to control. Deviations in the microbial structure of human gut occurred in the presence of PBDEs with a reduction of 15 % of Bacteroidetes, together with a decrease of 22 % of Firmicutes at the intermediate doses of PBDEs. Significant shifts were also verified for higher amounts of PBDEs at both phylum and family levels.

Conclusions: For the first time, the impact of PBDEs on the microbial homeostasis of human gut microbiota was taken into consideration, revealing noteworthy modifications with serious health implications even at oral exposure doses considered as safe by worldwide regulatory entities.

Fast Point-of-Care biomimetic receptor-based biosensor for detection and quantification of zoonotic Campylobacter

Marc Heyndrickx¹, Stella Givanoudi¹, Johan Robbens¹, Peter Cornelis¹, Gideon Wackers², Karolien Hertogs¹, Derick Yongabi², Michael J. Schöning³, Patrick Wagner²

¹Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Melle, Belgium, ²KU Leuven, Department of Physics and Astronomy, Leuven, Belgium, ³Aachen University of Applied Sciences, Institute of Nano- and Biotechnologies, Jülich, Germany

Abstract 4524

Background: Campylobacter is a zoonotic pathogen that causes gastroenteritis known as campylobacteriosis, which is a major public health concern and the most frequently reported food-borne disease in the EU since 2005. Based on the last EU report on food-borne outbreaks, campylobacteriosis has a notification rate of 64.8 per 100,000 population. Foodborne infections of Campylobacter are mostly associated with poultry products. Contamination can happen along the whole poultry production chain; consequently, a fast diagnostic on-site detection tool would be of high importance.

Materials/methods: We used surface imprinted polymers (SIPs) as artificial receptors for the recognition of Campylobacter. The SIPs were embodied with surface cavities complementary to the shape and size of Campylobacter. For the fabrication of SIPs, a thin layer of polyurethane polymer [PU], composed of bisphenol A, phloroglucinol and 4,4′-diisocyanatodiphenylmethane, was deposited on stainless steel substrate by spin coating. The bacteria imprints were formed on the PU layer using the stamping method. The pattern of Campylobacter imprints is created on the surface of the PU layer, after removing the bacteria using sodium dodecyl sulfate. Those stainless steel Campylobacter-imprinted chips were inserted into the flow cell of a heat-transfer method based (HTM) sensor, which measures the thermal resistivity ($R_{th}$) of the solution inside the flow cell.

Results: We applied a novel biomimetic sensor for the detection of the most prevalent zoonotic Campylobacter species, Campylobacter coli and Campylobacter jejuni. We performed dose-response measurements on SIPs imprinted separately with C. coli (see figure) or C. jejuni, by flushing into the sensor increasing bacterial concentrations in 1X PBS buffer (pH 7.4), ranging from 5x10³ to 500x10³ CFU/ml, alternated with PBS washing to remove the unbound bacteria. We observed a concentration-dependent increase in the measured $R_{th}$. The detection limit was calculated at around 30x10³ CFU/ml for both species. No cross-reactivity between the two species was observed with the sensor.

Conclusions: The biomimetic sensor presented in this work provides a sensitive method for the quantitative detection of the two most important foodborne Campylobacter species. This proof-of-concept fast detection system opens up perspectives for fast point of care testing in the food production chain.

Comparison of the performance of hydatid fluid and the recombinant antigen recDiPol in the diagnosis of cystic echinococcosis patients

Eylem Akdur Öztürk,1 Mesut Akıl,1 Fatma Bilgic,2 Carlos Sánchez Ovejero3, Raül Manzano Román4, Adriano Casulli5, Mar Siles-Lucas6, Nazmiye Altıntaş,1 Ayşegül Ünver

1Department of Parasitology, Ege University, Faculty of Medicine, İzmir, Turkey, 2Department of Parasitology, Katip Çelebi University, Faculty of Medicine, İzmir, Turkey, 3Sierrallana Hospital, Torrelavega, Spain, 4Proteomic Unit, Center for Cancer Research, Salamanca University, Salamanca, Spain, 5European Reference Laboratory for Parasites, Roma, Italy, 6Instituto de Recursos Naturales y Agrobiología de Salamanca, Salamanca, Spain

Background: The diagnosis of cystic echinococcosis (CE) mainly relies on imaging techniques but these are inconclusive in a percentage of patients. Therefore, there is a need for the development of immunodiagnostic tools that may complement imaging data. The aim of this study was to comparatively evaluate the diagnostic value of hydatid fluid (HF) and the new recombinant antigen recDiPol for a defined cohort of CE patients.

Materials/methods: A cohort of 79 CE patients was tested in this study. 44 patients had single cysts and 35 multiple cysts. Patients with several cysts were grouped to the most active cyst stage (number of CE1, CE2, CE3, CE4 and CE5 is 47, 11, 12, 4 and 5 respectively). Additionally, 28 sera from patients with other parasitic diseases (alveolar echinococcosis (AE) (3), fasciolosis (5), toxoplasmosis (2), taeniosis (5), trichinellosis (4), toxocariasis (16) and leishmaniasis (3)) were also tested. The new recombinant protein recDiPol containing selected epitopes from antigens B1, B2 and Ag5, was produced as a single recombinant antigen with GST. RecDiPol and HF were used in ELISA for the detection of total IgG in the above-mentioned patients.

Results: Overall sensitivity was higher for HF (89.8%) than recDiPol (83.5%). Seropositivity rate of patients with multiple cyst was higher than for patients with single cysts [94.2% vs. 86.3% against HF and 91.4% vs. 77.2% against recDiPol, respectively]. While sensitivity of HF was higher than recDiPol in active and transitional cysts (91.4% vs. 81.4%), sensitivity for patients with inactive cysts was higher for recDiPol (100%) than for HF (77.7%). In terms of cross-reactivity, HF showed false positive results for 3 AE, 1 trichinellosis and 1 teniosis patients, while only 1 teniosis patient showed positivity against recDiPol.

Conclusions: Both, HF and recDiPol showed a percentage of false negative and false positive results in this study, being recDiPol better than HF in specificity and detection of CE patients with inactive cysts. recDiPol did not reach in ELISA sensitivity levels comparable with HF, and thus new immunodiagnostic approaches should be explored for the detection and follow-up of patients with CE.

Abstract 4532

Unravelling colistin resistance diversity in clinical Acinetobacter baumannii: in-depth analysis of COL-R strain-profiling and genomics

Viviana Cafiso1, Veronica Dovere2, Stefano Stracquadanio*1, Flavia Lo Verde1, Alessandra Zega1, Giuseppe Pigola1, Simona Barnini3, Emilia Ghelardi2, Stefania Stefani1

1Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy, 2Azienda Ospedaliero-Universitaria Pisana, University of Pisa, Pisa, Italy, 3University of Catania, Catania, Italy, 4Bacteriology Unit of Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Background: Although the increased use of colistin (COL) for the therapy of difficult to treat Gram-negative bacteria can promote the emergence of COL-resistant (COL-R) strains, the adaptation of the bacterial species to the colistin pressure need in-depth investigation. Our study focused the strain-profiling and genomics of colistin resistance (COL-R) diversity existing in 9 clinical Extensively Drug-Resistant (XDR) Acinetobacter baumannii (Ab).

Materials/methods: COL-susceptibility was determined by repeated (10 times) Minimum Inhibitory Concentrations (MIC). COL-R inductions were performed using up to COL 2 mg/L (resistance cut-off). Population analysis profiles (PAP) were performed to investigate the presence of COL-R subpopulations. Whole Genome Sequencing was performed by Illumina Mi-Seq and the genomic epidemiology analysed by bioinformatic tools. The Variant Calling was used to identify genomic SNPs and pmrBCA, lpxA/C SNPs on Ab ACICU as RefGenome.

Results: In-depth analysis on COL-R strain-profiling displayed stable and reproducible MIC values (Full-Resistance) in 3 Ab strains, whilst 6 strains revealed unstable and variable MICs. Among these unstable phenotypes, COL-R induction revealed an inducible COL-R phenotype in 2 Ab strains (Adaptative-Resistance).

PAP analysis evidenced different COL-R subpopulations in the remaining Ab strains. In details, 3 Ab strains showed phenotype defined as "Heterogeneous-Resistance", in which on ≥32 mg/L COL agar-plates coexisted two morphologically different colony variants having two or more-fold COL MIC variations; 1 Ab strains exhibited a so-called "Homogeneous-Resistance" in which the two colony variants differed for only one-fold MIC dilution.

The genomic Phylogeny {gPhyl}, MLSTs and resistomes categorized the 9 Ab strains in 3 main clusters [cluster-I: gPhyl lineages I, ST-OX 1839, COL Full-Resistance, Resistome-I, harbouring diverse non-synonymous pmrB SNPs; cluster-II: gPhyl lineages II, ST-OX 1816 or ST-OX 218, COL Heterogeneous-Resistance, Resistome-III, carriers or not pmrB SNPs; cluster-III: gPhyl lineages III, ST-OX 1808, COL Adaptive/Heterogeneous/Homogeneous-Resistance, Resistome-IV, pmrB SNP carriers and non-carriers].

No Ab strain harbouring lpxA/C SNPs were found.

Conclusions: Our investigation, for the first time, find out the diversity of COL-resistance profiles among clinical COL-R A. baumannii defining the 4 different COL-R phenotypes and outline some genomic traits related to specific phylogenetic, MLST, resistome and pmrB-SNP clusters.

Abstract 4533

**Rapid nuc and mecA gene testing by polymerase chain reaction is useful to choose appropriate antibiotics in Staphylococcus aureus bacteremia**

Mami Ikemachi*1, Yamamoto Go2, Hiroshi Takekawa1, Kazuya Miyagawa1

1Kobe City Nishi-Kobe Medical Center, Kobe, Japan, 2Kobe City Medical Center General Hospital, Kobe, Japan

**Background**: Methicillin-resistant *Staphylococcus aureus* (MRSA) bacteremia has a higher mortality than Methicillin-susceptible *S. aureus* (MSSA) bacteremia and is often difficult to treat due to the multiple antimicrobial resistance. It is crucial to choose an appropriate antibiotic for *S. aureus* bacteremia but is difficult to predict it before antimicrobial susceptibility tests. Rapid and accurate detection of MRSA is critical to improve the prognosis of *S. aureus* bacteremia. Here we report the accuracy of nuc and mecA gene analysis, specific for *S. aureus* and MR staphylococci, respectively, using a fully automated ultra-rapid genetic analyzer directly from blood culture bottles and their efficacy on appropriate choice of antibiotics.

**Materials/methods**: We investigated nuc and mecA using GENECUBE® (TOYOBO, Japan) that is a 35 minute automated system to conduct direct PCR from biological materials. In this report, 75 cases in which staphylococci was detected in blood culture between January 2014 and December 2016 were included and the sensitivity and specificity for each gene were calculated. Furthermore, in 24 cases with *S. aureus* bacteremia during 2016, we retrospectively examined the ratio of antimicrobial changes based on the genotype.

**Results**: GENECUBE® revealed 39 cases as nuc positive (*S. aureus*) and 36 cases as nuc negative (except *S. aureus*). The sensitivity and specificity of nuc testing to detect *S. aureus* were comparable to conventional cultures (100% and 97.2%, respectively). mecA testing also exhibited high sensitivity and specificity to detect MRSA (95.2% and 93.9%, respectively). In 24 cases with *S. aureus* bacteremia, mecA positive (MRSA) and mecA negative (MSSA) were 12 cases each. As for mecA positive, the genotyping resulted in adding vancomycin in 11 cases (91.7%) and, in 1 cases (8.3%), discontinuing empirically administered broad spectrum β-lactam antibiotic on vancomycin. In cases of mecA negative, empirically administered vancomycin was discontinued in 2 cases (16.7%), a narrow-spectrum β-lactam antibiotic was chosen in 2 cases (16.7%), and antibiotics were de-escalated in 3 cases (25%).

**Conclusions**: Our study indicates that nuc and mecA genotyping by GENECUBE® is quick and accurate to separate MRSA from MSSA, which could result in an appropriate choice of antibiotics and better outcome against *S. aureus* bacteremia.

Microbial profile shift and miRNAs circulating in the saliva: what is their clinical correlation?

Maria Santagati1,2, Marco Ragusa1, Federica Mirabella1, Marina Scillato2, Ambra Spitale*2, Gino Mongelli2, Renata Rizzo4, Michele Purrello1, Stefania Stefani2

1University of Catania, University of Catania, Catania, Italy, 2University of Catania, Department of Biomedical and Biotechnological Sciences, Section of Microbiology, Catania, Italy, 3University of Catania, Department of Biomedical and Biotechnological Sciences, Section of Biology and Genetics G. Sichel, Catania, Italy, 4University of Catania, Department of Clinical and Experimental Medicine, Section of Child and Adolescent Psychiatry, Catania, Italy

Background: Several pathological conditions, as well as neuro-psychiatric diseases, may modify salivary molecules including metabolites, proteins, RNAs and bacterial populations. Autism Spectrum Disorder (ASD), a complex neurodevelopmental disorder whose etiopathogenesis is still unclear, is believed to be the complex result of a combination of genetic, epigenetic and environmental factors. Immune dysregulation and gastrointestinal abnormalities are of particular interest in the light of several papers reporting ASD-associated disturbances.

Many studies have reported that in ASD patients gut microbiota dysbiosis could play a key role in the alterations of brain structure and function development because of interactions between the Central Nervous System (CNS) and the gut microbiota; the so-called gut-brain axis. The aim of this study was to combine the alterations of the salivary microbiome and miRNA expression profiles in ASD and healthy subjects and their association with neuropsychological parameters to determine new biomarkers of ASD.

Materials/methods: In this experimental plan, were evaluated changes in the microbial composition of the salivary microbiome in 53 ASD and 27 HE (healthy) samples, sequenced on the Illumina MiSeq platform. To profile the circulating miRNA expression from saliva, NanoString Counter system assays were performed using the NanoString platform.

Results: The microbial profile by 16S rRNA sequencing analysis of ASD patients and HE subjects revealed statistically significant differences of abundance at the genus and species levels. In particular, Rothia, Filifactor, Actinobacillus, Weeksellaceae, Ralstonia, Pasteurellaceae, and Aggregatibacter increased their abundance rates in the saliva of ASD patients, while Tannerella, Moryella and TM7-3 decreased. In addition, 5 salivary miRNAs were statistically altered in ASD patients compared to HEs. Variations of both miRNAs and microbes were statistically correlated to different neuropsychological scores related to anomalies in social interaction and communication. Interestingly, we also found a negative correlation between salivary miR-141-3p expression and Tannerella abundance.

Conclusions: In our study, we demonstrated that miRNA and microbiome dysregulations found in the saliva of ASD children are associated with cognitive impairment of the subjects and a potential cross-talking between circulating miRNAs and resident bacteria alterations could exist. Moreover, these findings could pave the way to new potential tools for molecular diagnosis of ASD.

Abstract 4538

**Evaluation of a new commercial fosfomycin agar dilution-kit against reference agar dilution.**

Leanne Davies1, Lim Jones1, Federica Demetrio2, Stefano Pamponio2, Fabio Brocco2, Mandy Wootton*1

1University Hospital of Wales, Public Health Wales, Cardiff, United Kingdom, 2Liofilchem, Roseto degli Abruzzi, Italy

**Background:** Fosfomycin is an anti-Gram negative antimicrobial usually used to treat uncomplicated urinary tract infection (UTI). However, its use in multi drug resistant (MDR) Gram negative bacterial infections has increased due to few alternative treatment options. Reading fosfomycin susceptibility tests, either EUCAST disk diffusion or gradient strip MIC testing, is problematic for diagnostic laboratories. Colonies inside the zone of inhibition cause uncertainty when reading. Most laboratories cannot perform the reference method agar dilution (AD) and so we have evaluated a new commercial kit for fosfomycin MIC testing by AD.

**Materials/methods:** Reference method AD was performed using Mueller Hinton agar incorporating glucose-6-phosphate and fosfomycin concentrations from 0.06 to 1024 mg/L. Inocula were prepared in saline and 1ul (10⁴ cfu/ml) spotted onto the AD plates, which were incubated at 35±1°C for 16-20 hrs. Commercial fosfomycin AD kits were performed as per manufacturer’s instructions. 99 clinical isolates were tested: 69 E. coli (EC), 27 K. pneumoniae (KPN), 1 S. marcescens (SM), 1 E. cloacae (EClo) and 1 C. freundii (CF); some containing Extended Spectrum β-lactamases (ESBLs) and carbapenemases. MICs by both methods were compared.

**Results:** Essential agreement (within 1 log₂ dilution) and categorical agreement between the commercial fosfomycin AD kit and reference AD was 97.9% and 93.9% respectively. Major Errors (ME) and Very Major Errors (VME) at 5% and 1%. Most ME & VME were within 1 log₂ dilution. The comparison of MICs from the commercial fosfomycin AD kit to the reference AD method are shown in table 1. Endpoints on both the reference AD method and commercial fosfomycin AD kit were generally good, with a few isolates exhibiting trailing endpoints.

Delafloxacin (DLX) in the treatment of community-acquired bacterial pneumonia (CABP): patients with PORT Risk Class III-V

Rodolfo Alvarez-Sala1, Monica Popescu2, Laura Lawrence3, Sue Cammarata3, Daniela Zinzi*4

1La Paz University Hospital La Paz, Madrid, Spain, 2Sf. Pantelimon Emergency Clinical Hospital, Bucharest, Romania, 3Melinta Therapeutics, Morristown, United States, 4Menarini Ricerche, Firenze, Italy

Background: DLX is an IV/oral anionic fluoroquinolone approved for treatment of serious skin infections. A global Phase 3 trial of 859 patients with CABP was recently completed comparing DLX (300mg IV/ 450mg PO BID) to moxifloxacin (MOX; 400mg IV/ 400mg PO QD). This analysis includes PORT Risk Class III-V.

Materials/methods: Multicenter, randomized, double-blind trial of adults with CABP with ≥ 2 clinical symptoms: cough, sputum, dyspnea, and chest pain; physical signs; and radiographic evidence of pneumonia. Patients were randomized 1:1 to DLX or MOX treatment for 510 days (3 days IV minimum, then oral at investigator discretion). Primary clinical endpoint was the investigator assessed response at Test of Cure (TOC) 510 days after last dose. Clinical success was defined as complete/near resolution of signs and symptoms and no further antibiotics needed. Among secondary endpoints, all-cause mortality at Day 28 was assessed.

Results: 746 patients were randomized with PORT Risk Class III-V in the Intent-To-Treat (ITT) population: 60.5% male; mean age 61.5 yrs (23.9% ≥ age 75); 30.7% were PORT class IV-V; 30.1% multi-lobar pneumonia; 65% with CrCl < 90 mL/min. Overall bacterial pathogens were identified in 60.7% at baseline. Patients received mean 8.5 days of DLX (6.4/2.1 days of IV/oral) compared to 8.6 days of MOX (6.4/2.2 days of IV/oral). Clinical Success at TOC in the ITT was 91.0% (342/376) for DLX vs 89.2% (330/370) for MOX [95% CI: 2.6, 6.2]), and in the Clinically Evaluable population 94.8% (331/349) DLX vs 93.8% (320/341) MOX (95% CI: 2.5, 4.6). All-Cause Mortality at Day 28 was reported in n=8 DLX vs n=6 MOX patients. 14.4% DLX and 12.4% MOX patients had ≥ 1 treatment-related adverse events (AEs). Most common DLX events were mild to moderate diarrhea and transaminase elevations, which did not lead to treatment discontinuation. There were no QT-related AEs in DLX patients; one MOX patient reported QT prolongation.

Conclusions: IV/oral DLX demonstrated comparable efficacy to IV/oral MOX for the treatment of patients with moderate to severe CABP (PORT class III-V). DLX confirmed its favourable safety and tolerability profile without the potential for QT prolongation, phototoxicity, or major drug-drug interactions.

Abstract 4543

Usefulness of RAST-EUCAST directly from blood culture bottles combined with rapidly interpreted antibiogram reading to detect ESBL/carbapenemase-producing Enterobacterales

Victor Cerrudo Lopez*,1, Jose Luis Cortes Cuevas1, Sergio García-Fernández2, Rafael Canton Moreno2, Maria Isabel Morosini1, Ana Maria Sanchez Diaz1

1Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Rapid communication of antibiotic resistance phenotypes in blood culture isolates is relevant for patients' management and implies a challenge for clinical microbiology laboratories. We evaluated the possibility of infer the presence of beta-lactam resistance mechanisms directly from positive blood cultures using RAST-EUCAST disk-diffusion methodology and breakpoints interpreting subsequent antibiogram readings in Enterobacterales.

Materials/methods: 128 Enterobacterales (50 ESBL-producers, 29 carbapenemase-producers, 16 ESBL+carbapenemase-producers, 2 cepamicinase-producers, 23 wild-type and 8 ATCC) were spiked into contrived blood cultures bottles. Antibiotic susceptibility testing [amoxicillin-clavulanic, piperacillin-tazobactam, cefoxitin, ceftazidime, cefotaxime, ceftepime, aztreonam, ertapenem, imipenem, meropenem, ceftolozane-tazobactam and ceftazidime-avibactam] was performed directly from blood positive bottles by disk-diffusion according to RAST-EUCAST methodology. Reading of inhibition zones [including double-disk synergy (DDS) tests for ESBL detection] was performed at 4, 6 and 8h and RAST-EUCAST cut-off breakpoints for short incubation were applied.

Results: Detection percentages by synergy/RAST are shown in the Table. Apart from one isolate, 100% of ESBL-producing Escherichia coli and Klebsiella pneumoniae were detected at 6h. Moreover, 100% of carbapenemase-producing E. coli were recognized at 8h. Considering K. pneumoniae, 3 OXA-48 were not detected by RAST at 8h. Two false positive cefamicinase-producing K. pneumoniae were detected as ESBL-producers using RAST. As expected, wild-type isolates exhibited non-resistant phenotypes.

Conclusions: Early detection of ESBL/carbapenemase resistance mechanisms from positive blood cultures is feasible using RAST-EUCAST breakpoints when combined with interpretive antibiogram reading. Carbapenemase-producing K. pneumoniae were not accurately detected at 6h using only current RAST-EUCAST recommendations, and interpreted reading using other antibiotics [e.g., ertapenem] should be included. Differences of only 1-mm can lead to errors in interpretation thus being important to perform through interpretive reading. Disk-diffusion is an easy technique but useful enough to early communicate the resistance mechanism from positive blood cultures.

Longitudinal genomic analysis of IMP-1 metallo-β-lactamase-producing Enterobacteriaceae at a tertiary care hospital in north-east Japan

Hajime Kanamori*1,2, Yuko Makino1, Hiroaki Baba1,2, Kengo Oshima1,2, Tetsuji Aoyagi1,2, Koichi Tokuda1,2, Shiro Endo2, Hisakazu Yano1, Mitsuo Kaku1,4

1Department of Infectious Diseases, Internal Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan, 2Department of Intelligent Network for Infection Control, Tohoku University Graduate School of Medicine, Sendai, Japan, 3Department of Microbiology and Infectious Diseases, Nara Medical University, Kashihara, Japan, 4Division of Infectious Diseases and Infection Control, Tohoku Medical and Pharmaceutical University Hospital, Sendai, Japan

Background: Next-generation sequencing (NGS) has become a useful tool for molecular epidemiology of carbapenem-resistant Enterobacteriaceae (CRE) and/or carbapenemase-producing Enterobacteriaceae (CPE) in healthcare settings. In Japan, CPE infections and colonization are often caused by IMP-type metallo-β-lactamase-producers. In this study, we investigated sequential transmission of CPE with resistance mechanisms using NGS through a longitudinal hospital surveillance of CRE.

Materials/methods: One hundred fifty-seven CRE cases of infection or colonization are identified at a tertiary care hospital in Northeast Japan in a nine-year period between 2010 January and 2018 December, and 20 were excluded from this study since these CRE isolates were unavailable. A total of 137 non-duplicate clinical isolates of CRE were screened by PCR for \( \text{bla}_{\text{IMP}} \), \( \text{bla}_{\text{NDM}} \), \( \text{bla}_{\text{KPC}} \), \( \text{bla}_{\text{VIM}} \), and \( \text{bla}_{\text{OXA-48-like}} \). Of these CRE isolates, 33 (24.1%) were CPE that were further analyzed using NGS. Short-read libraries from DNA of all samples were sequenced using Illumina MiSeq. Specific genes and alleles, including resistance genes, plasmid replicon types, and multilocus sequence typing (MLST), were identified via the Center for Genomic Epidemiology’s bioinformatic pipeline.

Results: All carbapenemase genes identified were \( \text{bla}_{\text{IMP-1}} \) except one from an imported case with \( \text{bla}_{\text{NDM-4}} \). The \( \text{bla}_{\text{IMP-1}} \) was detected in 20 (61%) isolates of Enterobacter cloacae complex isolates, followed by Klebsiella pneumoniae \( (N=10, 30\%) \), Pantoea spp. \( (N=2, 6\%) \), and Escherichia coli \( (N=1, 3\%) \). This transmission of IMP-1-producing Enterobacteriaceae was primarily maintained by E. cloacae complex ST730 and ST252 as well as K. pneumoniae ST17 and ST1615, mostly co-harboring multiple resistance genes [e.g., \( \text{aac}(6')\text{-Ic} \), \( \text{qnrB6} \), \( \text{tet}(B) \), \( \text{fosA} \), \( \text{sul1} \) ] [Figure]. IncHI2 and IncHI2A were detected in 28 of 32 IMP-1-producers (87.5%) by in silico plasmid replicon typing. IMP-1-producing E. cloacae complex ST730 and K. pneumoniae ST1615 were found at the hospital for six and five years, respectively.

Conclusions: Our genomic analysis suggested prolonged clonal and plasmid transmission of \( \text{bla}_{\text{IMP-1}} \) within the hospital and provided insight into complex transmission mechanisms of resistance genes among intraspecies and interspecies of CPE.

Risk factors and outcomes associated with the carriage of tigecycline-non-susceptible vancomycin-resistant Enterococcus faecium

Johanna Kessel*1;2, Jennifer Karin Bender1, Guido Werner1, Matas Griskaitis1, Eva Herrmann1, Hubert Serve1;6, Kai Zacharowski1;7, Stefan Zeuzem1;8, Maria J.G.T. Vehreschild1;2, Thomas A. Wichelhaus1;9;10, Volkhard Kempf1;9;10, Michael Hogardt1;9;10

1University Hospital Frankfurt, University Center for Infectious Diseases (UCI), Frankfurt, Germany, 2University Hospital Frankfurt, Department of Internal Medicine, Infectious Diseases, Frankfurt, Germany, 3Robert Koch-Institute Wernigerode, Wernigerode Branch, Unit FG1 3 Nosocomial Pathogens and Antibiotic Resistances, National Reference Center for Staphylococci and Enterococci, Wernigerode, Germany, 4University Hospital Mainz, 4 Institute of Biostatistics, Epidemiology and Informatics, Mainz, Germany, 5Goethe University, Institute of Biostatistics and Mathematical Modelling, Frankfurt, Germany, 6University Hospital Frankfurt, Department of Medicine 2, Hematology/Oncology, Frankfurt, Germany, 7University Hospital Frankfurt, Department for Anesthesiology, Intensive Care Medicine and Pain Therapy, Frankfurt, Germany, 8University Hospital Frankfurt, Department of Internal Medicine 1, Gastroenterology, Frankfurt, Germany, 9University Hospital Frankfurt, Institute for Medical Microbiology and Infection Control, Frankfurt, Germany, 10University Hospital Frankfurt, University Center of Competence for Infection Control, Frankfurt, Germany

Background: Vancomycin-resistant E. faecium (VREF) is a common cause of healthcare-associated infections, particularly in severely ill and immunocompromised patients. Rising VRE infection rates in Germany caused an increased use of last resort antibiotics such as linezolid, daptomycin, and tigecycline. Resistance to these antibiotics is still rare and its impact on patient outcome is not well defined. Along with the changing VREF epidemiology we observed the emergence of VREF with additional tigecycline resistance (TVREF) at our hospital.

Materials/methods: At the University Hospital Frankfurt (UHF), we retrospectively identified patients with carriage or infection with TVREF between 02/2014-04/2017. We conducted a matched pair TVREF-VREF analysis to identify risk factors for TVREF carriage. Clinical events, namely detection of Clostridioides difficile, bloodstream infections (BSI), and patient death were recorded. Further, bed-to-bed contacts of TVREF cases and potential transmission routes were reconstructed. To identify putative transmission events genome sequences of 24 TVREF were analyzed by core genome multilocus sequence typing (cgMLST).

Results: In total, during the observation period 76 TVREF-positive cases (infection or colonization) were identified and compared to 152 VREF control patients. Of note, TVREF cases were associated with an increased previous exposure to tigecycline, an increased rate of bloodstream infections (BSI) with VREF or Candida spp., and a higher mortality. Whole genome sequencing provided evidence for the presence of room occupancy-associated transmissions of TVREF.

Conclusions: This study showed that tigecycline exposure is a main risk factor for the selection of TVREF. As observed for VREF, the hospital transmission of TVREF may occur despite strict contact precautions. TVREF- and Candida-BSI are associated with worse clinical outcome. Thus, regular antimicrobial stewardship and infection control interventions are of high importance to prevent the emergence and nosocomial spread of TVREF.

Abstract 4549

Assessing the impact of interventions designed to reduce the rate of postoperative sternal wound infection at a tertiary cardiothoracic centre

Thomas Locke*1,2, Helena Parsons3, Norman Briffa1, Thushan De Silva1,4, Thomas Darton1,4

1Department of Infection and Tropical Medicine, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, Sheffield, United Kingdom, 2Department of Microbiology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, Sheffield, United Kingdom, 3Department of Cardiothoracic Surgery, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, Sheffield, United Kingdom, 4The Florey Institute and Department of Infection, Immunity and Cardiovascular Disease, The University of Sheffield, Sheffield, UK, Sheffield, United Kingdom

Background: Postoperative sternal wound infection (SWI) is associated with significant excess morbidity and mortality. Since October 2012 we have introduced a series of interventions with the aim of reducing postoperative infection risk, in particular those caused by Staphylococcus aureus.

Materials/methods: Patients undergoing primary sternotomy between September 2010 and June 2018 were identified using retrospective review of local registry data. The CDC's criteria for surgical site infections was used to identify cases of SWI. Following a two-year pre-intervention observation, a phased bundle of interventions were introduced. Initially these targeted human and environmental factors and later included preoperative S. aureus decolonisation.

Results: 6903 procedures were performed of which 178 were complicated by SWI (2.6%), with 89 deep infections (1.3%). SWI was significantly associated with prolonged admission, readmission, additional operations and death. Multivariate analysis confirmed independent risk factors for SWI were CABG, non-elective procedures, female sex and seasonality, with higher rates between July and September. Prior to the introduction of any interventions, S. aureus was the most commonly isolated pathogen (46.5% of SWI). Time series analysis demonstrated a breakpoint in the infection rate corresponding to the earlier phases of intervention with a significant decrease in the intercept from 5.52 to 1.62 cases/100 patients/month. This decline was principally due to a reduction in S. aureus infection (3.9%, 95%CI 3.0-4.9 pre-intervention; 1.8,1.3-2.4 during targeted decolonisation). No significant effect was found on the rate of Gram-negative infections by any of the interventions deployed.

Conclusions: This dataset demonstrates the grave consequences of SWI for the individual and points to the additional demand this complication places on a healthcare system. A phased bundle of interventions resulted in a significant decrease in the rate of S. aureus SWI, however there was no discernible impact on SWI caused by Gram-negative bacteria. These infections tend to be more complex and often require long courses of broad spectrum antibiotics. This is of particular concern for this predominantly older cohort as they tend to have more comorbidities, are more prone to antibiotic side effects and also has wider implications for antimicrobial stewardship. Evaluation of additional preventative measures that target Gram-negative SWI are urgently required.

The temporal dynamics of Staphylococcus aureus carriage among healthcare workers in a tertiary referral hospital with a history of endemic methicillin-resistant Staphylococcus aureus, investigated by whole genome sequencing

Aoife Kearney*1,2, Peter Kinnevey1, Megan Earls1, Toney Poovelikunnel2,3, Grainne Brennan4, Anna Shore1, Hilary Humphreys2,3, David C. Coleman1

1Dublin Dental University Hospital, Trinity College Dublin, Dublin, Ireland, 2Royal College of Surgeons in Ireland, Dublin, Ireland, 3Beaumont Hospital, Dublin, Ireland, 4National MRSA Reference Laboratory, St. James Hospital, Dublin, Ireland

Background: This study investigated the prevalence and temporal dynamics of Staphylococcus aureus colonization among healthcare workers (HCWs) in a non-outbreak setting.

Materials/methods: Nasal swabs and oral rinses were collected from HCW volunteers on nine hospital wards during at least one of three consecutive six-month study phases occurring between 2017 and 2019. Samples were cultured on SaSelect and MRSASelect chromogenic media and confirmed as methicillin-resistant S. aureus (MRSA) or methicillin-susceptible S. aureus (MSSA) using routine identification methods. If an individual yielded both a nasal and oral S. aureus isolate during the same phase, a representative was chosen provided the antibiograms of the two isolates were identical; otherwise, one isolate was investigated per S. aureus-positive HCW per phase. Isolates underwent Illumina whole-genome sequencing and whole-genome multilocus sequence typing (wgMLST; BioNumerics, Applied Maths). Persistently colonised HCWs were detected by identifying those who yielded isolates from different phases that exhibited <24 allelic differences.

Results: A total of 326 HCWs were recruited from various frontline disciplines. Overall, 107/326 (33.1%) and 10 (3.1%) of HCWs were colonised with MSSA and MRSA, respectively. Ninety-four HCWs underwent repeat sampling, i.e. they were sampled during either two or all three phases. Slightly over half (48/94, 51.1%) of these repeat-sampled HCWs failed to yield S. aureus during both/all phases. Eleven of the 94 (22.0%) repeat-sampled HCWs yielded S. aureus during the first study phase only, indicative of non-persistent colonisation. Acquisition of S. aureus during the study period was suspected in 10 individuals, whereby S. aureus was not detected in their initial screen but was detected during subsequent sampling. Twenty-five of the 94 (27.0%) repeat-sampled HCWs yielded S. aureus on more than one occasion; nine of these HCWs harboured the same strain on two sampling occasions, indicative of persistent colonisation.

Conclusions: MSSA prevalence was as expected among HCWs, with MRSA prevalence lower than anticipated. Repeat screening combined with wgMLST revealed persistent S. aureus carriage in a small proportion of HCWs. Transient carriage was observed in 22% of HCWs sampled on more than one occasion.

Presenter email address: aoife.kearney@dental.tcd.ie
Background: Recently, an increasing number of OXA-244-producing Escherichia coli producers was identified from different parts of Switzerland by the National Reference Center for Emerging Antibiotic Resistance [NARA]. OXA-244 is a carbapenemase differing from OXA-48 by a single point mutation. Molecular investigations were carried out to better appreciate the different genetic features of those isolates and possibly contribute to better understand this emerging phenomenon.

Materials/methods: Sixteen OXA-244-producing E. coli clinical isolates were recovered from 11 different Swiss laboratories during the 2017-2019 period. Antimicrobial susceptibility testing was performed as well as whole genome sequencing (WGS). Conjugation assays were performed to evaluate the putative plasmid support of the \( \text{bla}_{\text{OXA-244}} \) gene. The ability to reliably detect the OXA-244 enzyme was evaluated with biochemical tests (Rapidec CARBA NP\textsuperscript{(bioMérieux)}, β-Carba test\textsuperscript{(Bio-Rad)}, NG-test Carba 5 lateral flow test [NG Biotech]). In parallel, the performances of different screening media, namely the ChromID\textsuperscript{®} CarbaSmart and ChromID\textsuperscript{®} ESBL [bioMérieux], and the mSuperCARBA [CHROMagar], were evaluated to detect OXA-244-producing E. coli.

Results: The 16 isolates showed variable degrees of susceptibility to carbapenems and expanded-spectrum cephalosporins, with 10 isolates producing an ESBL (CTX-M-14b, CTX-M-27, TEM-1B, TEM-33), two CMY-2 producers and five being susceptible to broad-spectrum cephalosporins. The main sequence type (ST) was ST38 (n=6), but a total of 7 STs was identified. WGS revealed a perfect identity with a recently-identified strain from Germany. No plasmid was detected nor transferred by conjugation, suggesting a chromosomal location for the \( \text{bla}_{\text{OXA-244}} \) gene. Among the different tests evaluated, only the NG-test Carba 5 gave positive results, while the only screening medium on which the corresponding isolates could be detected was the mSuperCARBA.

Conclusions: We evidenced here the emergence of OXA-244-producing E. coli in Switzerland, following other reports from neighboring countries, with an identical clone being identified in Germany. This emergence was mainly due to a single clonal background, but also to some other clones. Because of the weak carbapenemase activity of OXA-244 and the variable degree of resistance to β-lactams of the corresponding isolates, their detection was challenging, with the mSuperCARBA medium and the NG-test Carba 5 being the most appropriate tools.

Abstract 4553

Multi-centre study for the evaluation of BioFire FilmArray Pneumonia Plus for the rapid microbiological diagnosis of low respiratory tract infections

Eleonora Riccobono*1, Teresa Spanu2,3, Filippo Allegrucci4,5, Claudia Tiberio6, Simone Ambretti7, Paolo Bottino8, Valeria Ghisetti9, Giuliana Lo Cascio10, Gian M. Rossolini1;11

1University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy, 2Fondazione Policlinico Universitario A. Gemelli IRCCS, Laboratory Sciences & Infectious Diseases, Rome, Italy, 3Università Cattolica del Sacro Cuore, Institute of Microbiology, Rome, Italy, 4University of Perugia, Medical Microbiology, Dept. of Medicine, Perugia, Italy, 5Perugia General Hospital, Microbiology, Perugia, Italy, 6Catugno Hospital, Azienda Ospedaliera dei Colli, Microbiology and Virology Unit, Naples, Italy, 7S. Orsola-Malpighi University Hospital, Unit of Clinical Microbiology, Bologna, Italy, 8Città della Salute e della Scienza Hospital, Laboratory of Microbiology and Virology, Turin, Italy, 9Ospedale Amedeo di Savoia, Laboratory of Virology and Molecular Biology, Turin, Italy, 10Azienda Ospedaliera Universitaria Integrata, Microbiology and Virology Unit, Verona, Italy, 11Careggi University Hospital, Clinical Microbiology and Virology Unit, Florence, Italy

Background: Low respiratory tract infections (LRTIs) are common and serious nosocomial infections in ICUs and are responsible for longer hospital stay, higher costs, and greater mortality. Accurate and timely microbiologic diagnostic approaches for LRTIs are urgently needed to guide targeted therapeutic choices and reduce the impact of ineffective empiric antibiotic regimens and the overuse of antibiotics. We carried out a multicentric study aimed to evaluate the performance of BioFire® FilmArray® Pneumonia Plus panel (FAP). This syndromic panel allows the rapid detection (about 1 hour), directly from respiratory samples, of 34 targets for the most common bacterial, viral, and atypical bacterial pathogens responsible for LRTIs.

Materials/methods: The study was performed on 475 low respiratory samples (sputum, BAS, BAL and ETA) from 8 microbiology laboratories in Italy. All samples were simultaneously analysed with FAP and the standard of care (SoC) consisting in culture for bacteria detection and sometimes in other molecular methods for virus/atypical bacteria detection.

Results: Three samples resulted invalid by FAP and were excluded from the analysis. A total of 52 samples resulted negative for both FAP and SoC. From the 420 remaining samples were obtained 745, 84 and 15 bacterial, viral, and atypical bacterial target identifications, respectively. Correspondences between FAP and SoC were as follow: 468 bacterial targets were identified by both FAP and SoC, 251 by FAP only, and 26 just by SoC; 19 viral targets were detected by both methods, 63 by FAP only (not always investigated by SoC) and 2 solely by SoC; 11 atypical bacterial targets, were identified by both methods, 3 just by FAP and 1 was revealed by SoC only.

Conclusions: FAP showed excellent performances in detecting almost all the main respiratory pathogens and in revealing additional pathogens. Therefore, FAP is a promising test for the rapid microbiological diagnosis of respiratory infections and could have a positive impact on patient outcome and antibiotic stewardship. The absence of some targets in the panel and the epicitical value of FAP additional detections should be considered.

Molecular epidemiology of Acinetobacter baumannii in Sudan
Einas Osman1, Sara Ali2, Daire Cantillon3, Julia Wille4, Harald Seifert4, Paul G. Higgins5,6, Leena Al-Hassan*3
1Ibn Sina University, Bioscience Research Institute, Khartoum, Sudan, 2International University of Africa, Medical Laboratory Sciences, Al Khurtum, Sudan, 3Brighton & Sussex Medical School, Brighton and Sussex Centre for Global Health Research, Falmer, United Kingdom, 4University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 5German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 6University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany

Background: Acinetobacter baumannii is listed as one of the ‘priority pathogens’ by the World Health Organization due to its multi-drug resistance and global spread. A. baumannii, however, is poorly investigated in many low- and middle-income countries, thereby creating knowledge gaps on the epidemiology of this pathogen. The data presented here is a multi-centre study of the molecular epidemiology of A. baumannii in Sudan.

Materials/methods: Seventeen A. baumannii isolates were recovered from patients in 3 hospitals in Khartoum, Sudan. Species identification was confirmed by the gyrB multiplex method [1], and presence of the intrinsic blaOXA-51-like gene [2] in comparison with the Pasteur’s multilocus sequence typing (MLST. Antimicrobial susceptibility was performed by disk-diffusion. Whole genome sequencing was performed using the Illumia Miseq platform. Molecular epidemiology was investigated by core-genome MLST (cgMLST) using Ridom® SeqSphere+. Pasteur sequence types (ST) and the resistome was extracted using the Resfinder database.

Results: cgMLST is summarized in Fig-1. The isolates clustered with international clonal lineages IC1, IC2, or IC9, of which 15 were IC2. IC2 was subdivided into three STs separated by >200 allelic differences. Within these STs was evidence of transmissions (shaded in grey, or >1 isolate in a node). All isolates were multi-drug resistant, and harboured multiple resistance genes: OXA-23 (15/17; 88%) and NDM-1 (n=6; 35%), and TEM-10 (13/17; 76%) β-lactamases. All isolates contained the aminoglycoside-modifying enzymes aph(3’)-Ia and aph(6)-Ia, and 13/17 (76%) contained mphE and/or msrE contributing to macrolide resistance. 9/17 isolates (6%) were in possession of the tetracycline resistance genes tetA or tetB.

Conclusions: IC2-OXA-23 A. baumannii clone is prevalent across Khartoum hospitals, with a high burden of MDR to a variety of drug classes. OXA-23 is frequently present with other genes such as NDM-1 and aminoglycoside modifying enzymes. A systematic genomic study of A. baumannii in the Middle East and Africa is required to understand the local dissemination of the pathogen.

Figure 1: Minimum spanning tree of A. baumannii using cgMLST

Phage-MR003 prevents infection caused by clinical isolated methicillin-resistant Staphylococcus aureus in mouse wound model

Tomoya Suda*1, Tomoko Hanawa2, Yasunori Tanji3, Kazuhiko Miyanaga3, Hiroaki Ohnishi4, Takeaki Matsuda1,5

1Kyorin University School of Medicine, Department of General Medicine, Mitaka, Japan, 2Kyorin University School of Medicine, Department of Infectious Diseases, Mitaka, Japan, 3Tokyo Institute of Technology Suzukakedai Campus, School of Life Science and Technology, Yokohama, Japan, 4Kyorin University School of Medicine, Department of Laboratory Medicine, Mitaka, Japan, 5Kyorin University School of Medicine, Department of Traumatology and Critical Care Medicine, Mitaka, Japan

Background: Phage therapy is expected as an option for therapeutic tool against multi-drug resistant bacterial infections. ΦMR003, Staphylococcus aureus phage isolated from sewage influent, exhibits a broad host range against MRSA strains collected from patients at Kyorin university hospital in 2015 to 2016 (Peng et al., 2019). To assess the efficacy of ΦMR003 in vivo, bacteriological and pathological effects of phage administration were analyzed using murine wound infection model.

Materials/methods: The KYMR116 and KYMR117 strains in the present study were classified as CA-MRSA by MLST. KYMR117 was classified as a USA300 clone by the presence of pvl, arcA genes, and genotype of ST/t008 (Hanawa et al., 2019). To prepare murine wound infection model, a full-thickness cutaneous wound was created on the back of each BALB/c mouse (6 w, female). After the inoculation of KYMR116 or KYMR117 at the wounding sites, ΦMR003 was subsequently administered. The number of viable bacteria in the wounds was quantified and the localization of bacterial cells and neutrophils in the skin lesions was analyzed by Hematoxylin-Eosin and Giemsa staining or immunohistochemical staining.

Results: Abscesses were formed in both KYMR116 and KYMR117 infected mice within 48-h, and 1.4×10⁹ ± 4.0×10⁸ cfu and 2.3×10⁸ ± 1.3×10⁸ cfu of bacteria were detected in the wounds infected with KYMR116 and KYMR117, respectively. On the other hand, abscesses were not formed and the number of KYMR116 and KYMR117 bacterial cells decreased to 4.1×10⁵ ± 5.3×10⁵ cfu and 5.0×10⁵ ± 1.2×10⁶ cfu, respectively, in the mice administered ΦMR003. Additionally, fewer neutrophils were recruited in the phage-treated wounds compared to the non-treated.

Conclusions: ΦMR003 decreased bacterial load and suppressed inflammation against CA-MRSA strain, KYMR116 and KYMR117. In addition, KYMR117, the virulent strain, was equivalent to KYMR116 regarding the susceptibility to ΦMR003. These results support the potential use of ΦMR003 as a therapeutic phage against MRSA wound infection.

Abstract 4557

**Antibacterial activity of the novel compound \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br versus methicillin-resistant *Staphylococcus aureus***

Jonathan Betts¹, Patrick Roth², Apostolos Liakopoulos³*, Ulrich Schatzschneider², Roberto La Ragione¹

¹University of Surrey, School of Veterinary Medicine, Guildford, United Kingdom, ²Julius-Maximilians-Universität, Würzburg, Germany, ³Institute Biology Leiden (Sylvius Laboratory), Leiden, Netherlands

**Background:** *Staphylococcus aureus* is an important nosocomial pathogen, which is commonly multidrug-resistant and can cause serious skin and soft tissue infections in animals and humans. Methicillin-resistant *S. aureus* (MRSA) has been prioritised on the World Health Organisations priority pathogens list, for the research and development of novel antibiotics. Previously, novel manganese complexes have shown potential as antibacterial agents against multidrug-resistant bacteria. The aim of this study was to assess the *in vitro* and *in vivo* activity of the novel compound \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br against MRSA.

**Materials/methods:** Four well characterised strains of MRSA and methicillin susceptible *S. aureus* (MSSA) were used in this study. Minimum inhibitory concentrations for \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br were determined via broth microdilution assays and kill kinetics versus MSSA and MRSA strains were determined over 24 h. The toxicity of \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br and efficacy of the compound versus MSSA and MRSA strains *in vivo*, was determined in the *Galleria mellonella* model of infection. The Log rank test (Mantel-Cox) was performed to test for significant differences in larval survival.

**Results:** Strong antibacterial activity was observed against MSSA/MRSA with mean MICs of 2-2.67 µg/mL. Data from kill-kinetic assays indicated that \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br was bactericidal against MRSA/MSSA strains, with >3log reduction in bacterial numbers compared to the no drug control. The compound was found to be non-toxic in *G. mellonella* at concentrations ≥100 times those required for bacterial killing. *In vivo* testing in the *Galleria* model found that treatment with \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br significantly increased survival of MRSA/MSSA infected larva compared to PBS (\(p = <0.013\)), with survival rates of 88% versus 46%.

**Conclusions:** Results from this study not only demonstrate that \([\text{Mn(bpen-cholamide)}(\text{CO})_3]\)Br effectively reduces MRSA/MSSA numbers *in vitro*, but also significantly reduces mortality in MRSA/MSSA infected *G. mellonella* larvae, with no compound toxicity observed. This novel compound may have potential as a treatment for MRSA/MSSA infections.

**Presenter email address:** a.liakopoulos@biology.leidenuniv.nl
Interspecific transfer of a bla\text{VIM-2}-containing plasmid between \textit{Pseudomonas} spp. during a nosocomial outbreak

Jannette Pirzadian\textsuperscript{*1}, Nikolaos Strepis\textsuperscript{1}, Astrid Heikema\textsuperscript{1}, Willemien Zandijk\textsuperscript{1}, Heidy Koene\textsuperscript{1}, Wil Goessens\textsuperscript{1}, Margreet C. Vos\textsuperscript{1}, Corné H. Klaassen\textsuperscript{1}, Juliëtte A. Severin\textsuperscript{1}

\textsuperscript{1}Erasmus MC University Medical Center Rotterdam, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands

Background: \textit{Pseudomonas} spp. are Gram-negative bacteria found in hospital wet niches. Since 2003, carbapenemase-producing, \textit{bla}\textsubscript{VIM}\textsuperscript{-}positive \textit{P. aeruginosa} have been isolated from patients and sinks in our hospital; these isolates belonged to “high-risk” sequence types ST446 and ST111. Previously, a \textit{bla}\textsubscript{VIM-2}\textsuperscript{-}containing plasmid was identified in \textit{P. aeruginosa} S04 90, a ST446 clone isolated in 2009 from a patient admitted to intensive care (IC). Our aim was to determine if this plasmid was also present in other \textit{Pseudomonas} spp.

Materials/methods: From this IC ward, \textit{bla}\textsubscript{VIM}\textsuperscript{-}positive \textit{Pseudomonas} spp. isolated between 2013-2016 from patients/sinks were selected. MALDI-TOF (Bruker) was used for species identification, and PCR was used to confirm the presence of \textit{bla}\textsubscript{VIM}. DNA was extracted and sequenced using Illumina iSeq 100 and Nanopore MinION/GridION. Hybrid assemblies were generated using Unicycler. Assembled plasmids were visualized using Bandage, and annotated with Prokka. Resistance genes were screened using ResFinder/CARD. BLASTn and Mauve were used to identify plasmids and align sequences.

Results: Six isolates, and \textit{P. aeruginosa} S04 90 as a reference, were sequenced. These isolates comprised one \textit{P. oleovorans}, one \textit{P. gessardii}, one \textit{P. putida}, and three other \textit{P. aeruginosa} of different genotypes. \textit{P. aeruginosa} S04 90 and \textit{P. putida} were clinical isolates, while the remaining five were sink isolates. In all generated plasmid sequences, \textit{bla}\textsubscript{VIM-2} was found; additionally, \textit{bla}\textsubscript{VIM-2}\textsuperscript{-}containing plasmid sequences were identical to the reference plasmid sequence. For one \textit{P. aeruginosa} sink isolate, copper/silver resistance genes were also found in the plasmid sequence.

Conclusions: \textit{P. aeruginosa} S04 90 possessed a \textit{bla}\textsubscript{VIM-2}\textsuperscript{-}containing plasmid that matched the plasmid sequences of six other \textit{Pseudomonas} spp. isolated in the same ward; five of these were sink isolates. We hypothesize that \textit{bla}\textsubscript{VIM-2}\textsuperscript{-}positive \textit{Pseudomonas} spp. have sustained in our hospital’s sinks after possible human-environment transmission events, and have exchanged the \textit{bla}\textsubscript{VIM-2}\textsuperscript{-}containing plasmid to other \textit{Pseudomonas} spp. Copper/silver resistance genes may have contributed to their persistence in sinks, as copper and silver were added to our hospital’s tap water during the outbreak period to prevent \textit{Legionella} growth. Therefore, it is crucial for effective infection prevention and control to screen for \textit{bla}\textsubscript{VIM}\textsuperscript{-}positive \textit{Pseudomonas} spp. and for the presence of plasmids in sinks.

Presenter email address: j.pirzadian@erasmusmc.nl
**The prevalence of puerperal sepsis causing emm28 Streptococcus pyogenes in four Nordic countries**

1University of Turku, Institute of Biomedicine, Turku, Finland, 2Karolinska Institute, Department of Microbiology, Tumour and Cell Biology, Stockholm, Sweden, 3Norwegian Institute of Public Health, Division for Infection Control and Environmental Health, Oslo, Norway, 4Landspitali University Hospital, Department of Clinical Microbiology, Reykjavik, Iceland, 5University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland, 6Public Health Agency Sweden, Stockholm, Sweden, 7Finnish Institute for Health and Welfare, Department of Health Security, Helsinki, Finland, 8Landspitali University Hospital, Department of Infectious Diseases, Reykjavik, Iceland, 9Turku University Hospital, Turku, Finland

**Background:** Streptococcus pyogenes or Group A streptococcus (GAS) is a human pathogen which causes a wide range of infections. M-protein, encoded by the emm gene, is one of the main virulence factors of GAS. Sequencing of the hypervariable region of emm is the traditional typing method for GAS. In the Nordic countries, emm28 is one of the most common causes of invasive GAS disease. A specific feature of emm28 GAS is its association with postpartum infections. We aimed to investigate the prevalence and demographic characteristics of invasive emm28 GAS infections reported in four Nordic countries, namely Finland, Sweden, Norway and Iceland.

**Materials/Methods:** This is a retrospective, population- and register-based study on invasive emm28 GAS disease in four Nordic countries. National Infectious Disease Registers of each participating country were used to search for invasive emm28 GAS cases. Demographic data of the patients (gender, age and infection type if available) were included in the analysis. The yearly proportion of emm28 of all documented invasive GAS cases was calculated.

**Results:** Among altogether 7326 invasive GAS cases, 1352 (18.5 %) were caused by a emm28 GAS isolate in the participating countries. Due to varying reporting history, the study period varied between countries; 1990-2015 (Iceland), 2006-2016 (Norway), 2002-2015 (Sweden) and 2004-2015 (Finland). The median age of patients infected by emm28 GAS was 63 years, and 53 percent of the cases were women. The cases were divided into four age groups, <20, 20-40, 41-60 and >60 years. Within the age group of 20-40 years, women were significantly overrepresented (82.8 %, 222/268 cases, p<0.001). In this age group of women, altogether 102 cases were associated with delivery or puerperal infection (median age 31 years).

**Conclusions:** Invasive emm28 GAS infections are common in the Nordic countries. There is a clear association of emm28 GAS infections with young women of childbearing age. The underlying molecular mechanisms warrant further studies.

Abstract 4561

**Evaluation of the diagnostic accuracy of a rapid dengue NS1 antigen lateral flow immunochromatography test in UK returned travellers**

Benjamin Patterson¹, Kirsten Macgregor*², Stephanie Wilmore², Tim Brooks², Robert Davidson¹, Alastair McGregor¹

¹Northwick Park Hospital, Infectious Diseases Department, London, United Kingdom, ²Rare and Imported Pathogens Laboratory, Public Health England, Porton, United Kingdom

**Background:** Dengue Fever (DF) is an important cause of illness in travellers returning to the UK. DF is often impossible to distinguish clinically from other imported infections and most UK hospitals do not have access to an on-site test. Although there is no effective anti-viral treatment, a severe vascular leak syndrome, which carries significant mortality, occurs in a small proportion of cases. Rapid diagnosis at the point of care would help identify these patients and simplify clinical decision making. Our aim was to compare the performance of a rapid diagnostic test with the reference standard in a select UK returned traveller population.

**Materials/methods:** We tested stored frozen specimens (plasma/serum), taken from adult patients who were symptomatic following return from a dengue endemic region (defined as South-East Asia, South Asia, the Caribbean, Central and South America). Patient samples were included if they had had documented onset of an acute febrile illness within seven days of return, and sample collection had occurred within five days of illness onset. Testing was performed using the BIO-RAD NS1 antigen rapid diagnostic lateral flow immunochromatography test (NS1-RDT), following the manufacturers’ instructions. The operator was blinded to the reference standard result. The NS1-RDT result was then compared with the reference standard reverse transcriptase polymerase chain reaction (RT-PCR) result.

**Results:** 79 individuals met the inclusion criteria. Of these, 41 (51.9%) had dengue virus infection according to the reference standard (RT-PCR positive). The sensitivity of the NS1-RDT was 85.4% (95% CI: 70.8, 94.4) and the specificity was 100% (95% CI: 90.7, 100) in this cohort. The positive predictive value was 96.2% (95% CI: 81.7, 98.6) and the negative predictive value was 85.2% (95% CI: 74.1, 91.1) assuming a disease prevalence of 0.5. True positives and false negatives were compared (table).

**Conclusions:** NS1-RDT is an accurate tool for early identification of DF in a select UK returned traveller population.

Bioinformatic studies and investigation of the immunogenicity of a vaccine candidate composed of ExoS and PcrV of Pseudomonas aeruginosa against urinary tract infections in an animal model

Mehri Habibi*, Hedyeh Alaie1, Saeid Bouzari1, Mohammad Reza Asadi Karam1

1Pasteur Institute of Iran, Tehran, Iran

Background: Pseudomonas aeruginosa causes different infections such as urinary tract infections (UTIs). Antibiotics are common therapy against these infections, but the increased rate of antibiotic resistance will complicate treatment of the infections in the future. Vaccines could be an alternative approach against UTIs. Exotoxin S (ExoS) as an effector toxin and PcrV as a compartment of type III secretion system are among the most important virulence characteristics of P. aeruginosa. Thus, in the present study, we analyzed the ExoS and PcrV of P. aeruginosa by in silico studies, and then the selected fragments were expressed and purified. Finally, the immunogenicity of the purified protein was evaluated in animal model.

Materials/methods: The ExoS and PcrV sequences of P. aeruginosa were investigated by bioinformatics studies. Then, the best sequences were selected, fused together by the overlapped PCR, and cloned into expression vector. The protein was expressed in BL21 (DE3) and purified by nickel column. The purified protein was analyzed by SDS-PAGE and Western blot. Mice were subcutaneously vaccinated with the purified protein in 2-weeks intervals. Then, serum and urine samples were collected from the mice for measurement the antibody responses by ELISA.

Results: By using the bioinformatics softwares, the best immunogenic segments of ExoS and PcrV were selected as a fusion construct. The expressed fusion protein ExoS:PcrV showed band at the size of 59 KD. Mice immunized with the fusion protein induced higher humoral immune responses in both serum (IgG and IgA) and urine (IgG) than control mice that recieved PBS alone ($P<0.05$). Furthermore, it was also found that the designed fusion protein evoked production of both Th1 (IgG1) and Th2 (IgG2a) responses in the immunized mice.

Conclusions: Because of the important role of P. aeruginosa strains among UTIs, designing of an effective vaccine could have an important role in prevention or treatment of these infections, especially in hospital environments. We found that a vaccine formulation based on the most important fragments of ExoS and PcrV could be considered as an ideal vaccine candidate against UTI. However, further analyses are necessary to demonstrate the efficacy of the designed candidate against UTIs.

PK/PD of intravenous and oral fosfomycin in neonates with presumed serious bacterial infection

Zoe Kane1, Silke Gastine1, Phoebe Williams2,3, James A Berkley2,3, Sally Ellis4, Erika Correia4, Christopher Darlow5, William Hope5, Mike Sharland6, Joe Standing1,6

1UCL Great Ormond Street Institute of Child Health, London, United Kingdom, 2KEMRI, Welcome Trust Research Program, Kilifi, Kenya, 3University of Oxford, Center for Tropical Medicine & Global Health, Oxford, United Kingdom, 4GARDP – Global Antibiotic Research & Development Partnership, Genève, Switzerland, 5University of Liverpool, Liverpool, United Kingdom, 6St George’s University, London, United Kingdom

Background: Treatment of Multi Drug Resistant neonatal sepsis has become a major challenge. Fosfomycin could be part of an empiric treatment regimen in settings where there are high levels of resistance to empiric ampicillin/gentamicin [SOC] and/or ceftriaxone therapy. Fosfomycin PK data in neonates is limited, with no oral PK (PO) data. Here we report model-based estimation of fosfomycin CL, V, T1/2, F% and CSF penetration in hospitalised neonates.

Materials/methods: The NeoFosfo study (ClinicalTrials.gov: NCT03453177) was conducted at Kilifi County Hospital, Kenya. 61 neonates received SOC plus 100mg/kg q12h Fosfomycin, with sample size determined by simulation-estimation. A cross-over design with 2 samples randomized to 4 time slots after the 1st IV and 1st oral dose, respectively gave >80% power for CL, V and F% estimation. CSF sampling was opportunistic. PK modelling was performed using nonlinear mixed effects modelling with NONMEM 7.3. Covariates were selected on biological plausibility or correlation with model parameter variability. Monte Carlo based simulations (n=1000) of plasma concentrations were performed in the context of two PD targets; AUC:MIC ratio and fT>MIC.

Results: Of 238 plasma and 15 CSF concentrations, IV and PO plasma levels ranged (mean) from 7 -576 (202) and 7 -206 (70) respectively, with CSF from 16-66 (38) µg/mL.

A 3-compartment model with first order absorption and allometric scaling adequately described our data. Significant covariates were PMA and PNA in maturation functions on CL and CSF protein on uptake into CSF. Population estimates (%RSE) for CL and Vc were 8.9 L/hr (7.3) and 18.8 L (4.1). Inter-individual variability was 26% (28.6) and 14% (48.3) respectively. F% was estimated at 50% (13.1), Ka at 0.1 hr (23.1) and CSF penetration 0.32 (9.5).

Conclusions: The NeoFosfo study enabled the development of a Population PK model that adequately describes IV and oral Fosfomycin plasma and CSF levels in neonates. Alongside emerging in-vitro hollow fibre data it provides a valuable tool to inform future neonatal sepsis empiric treatment candidates.

Abstract 4570

**Genome-wide transcriptional responses of Escherichia coli with different levels of zinc tolerance to zinc chloride exposure**

Vanessa Johanns¹, Silver Wolf², Lennard Epping², Antina Lübke-Becker³, Torsten Semmler², Birgit Walther*¹, Lothar H. Wieler⁴

¹Robert Koch Institute, Advanced Light and Electron Microscopy, Berlin, Germany, ²Robert Koch Institute, Microbial Genomics (NG1), Berlin, Germany, ³Freie Universität Berlin, Institute of Microbiology and Epizootics, Berlin, Germany, ⁴Robert Koch Institute, Methodology and Research Infrastructure, Berlin, Germany

**Background:** The trace metal zinc is an important catalyst and structural cofactor in nearly all aspects of cell metabolism and plays an essential role in maintaining a well-balanced intracellular zinc homeostasis in most bacterial species. While zinc deprivation hampers bacterial growth, zinc excess could be lethal. We have recently reported different minimum inhibitory concentrations (MICs) for ZnCl₂ associated with commensal *Escherichia coli* mirroring a broad phylogenetic background. However, reasons for these ZnCl₂ MIC differences are not fully understood yet. To investigate whether these differences in zinc tolerance might be associated with significant differences in gene expression among closely related *E. coli*, we used an RNA sequencing (RNA-Seq) approach to characterize the global transcriptomes comparatively.

**Materials/methods:** Our study focused on comparing two distinct *E. coli* of sequence type 617 with a) 1024 µg/ml ZnCl₂ MIC (RKI6122) and b) 256 µg/ml ZnCl₂ MIC (IMT11012). Both were challenged with 1.0 mM ZnCl₂ during exponential growth in supplemented minimal medium for 10 min, while untreated cultures served as controls. Three consecutive biological replicates were subjected to RNA sequencing after total RNA isolation with RNA Snap™. We comparatively characterized the global transcriptomes and identified various differentially expressed genes using the computational pipeline SCORE, which is based on a set of established tools, including DESeq2, edgeR, limma, NOISeq and sleuth.

**Results:** Transcriptional changes for each isolate were compared to those obtained from the corresponding unchallenged controls. Zinc exposure of both *E. coli* resulted in transcriptional changes of genes involved in zinc, iron and copper homeostasis and factors involved in response to envelope stress such as the phage-shock protein A (pspA). Gene transcripts involved in amino acid biosynthesis (e.g. cobalamin-independent methionine synthase (MetE)) showed significantly reduced fold changes for both isolates. In addition, differences were detected for transcripts of the biofilm adhesin polysaccharide encoding gene (*pgaB*), which was downregulated in IMT11012 but remained unaltered in RKI6122.

**Conclusions:** The transcription of genes involved in zinc, iron and copper homeostasis of *E. coli* are affected by zinc chloride exposure. Further research is needed to investigate the putative role of biofilm formation capabilities in *E. coli* expressing increased tolerance towards zinc.

Extended antibiotic panel to analyse the susceptibility of Enterobacteriaceae by the MALDI-TOF MS-based MBT FAST Assay

Katrin Sparbier1, Oliver Drews1, Markus Peer1, Ilka Davina Nix2, Evgeny A. Idelevich1, Karsten Becker3, Markus Kostrzewa*1

1Bruker Daltonics GmbH, Bremen, Germany, 2Münster, Medical Microbiology, Münster, Germany, 3Greifswald, Friedrich Loeffler-Institute of Medical Microbiology, Greifswald, Germany

Background: The MBT FAST (MALDI Biotyper Fast Antimicrobial Susceptibility Testing) assay has recently been suggested for rapid antimicrobial susceptibility testing of bacteria by MALDI-TOF MS. Here, we extended the previously described panel of 6 antibiotics to the 10 most common antibiotics employed for severe enterobacterial infections.

Materials/methods: A collection of 25 Enterobacteriaceae comprising different species with various resistance patterns was analysed for its susceptibility towards ten antibiotic compounds (piperacillin/tazobactam, cefotaxime, ceftazidime/avibactam, ertapenem, meropenem, ciprofloxacin, gentamicin, fosfomycin, tigecycline, and colistin) at EUCAST breakpoint concentrations in triplicate by MBT FAST. The workflow was supported by dedicated hardware tools [incubation chamber and broth removal stamp] to increase reproducibility and usability. MICs were determined by the broth microdilution method according to EUCAST as reference method. Tested incubation time for MBT FAST was 4.5 and 5 h. Spectra were evaluated by a prototype software using optimised evaluation parameters and cutoff values for each antibiotic.

Results: In general, the increase of incubation time from 4.5 h to 5 h decreased the standard deviation of the calculated score values and increased the accuracy compared to the CLSI microdilution. Incubation for 4.5 h resulted in 10 invalid growth controls in contrast to only 5 invalid samples after 5 h incubation. Compared to the reference method, the accuracy for ceftazidime/avibactam, ciprofloxacin, colistin, ertapenem, gentamicin and tigecycline was > 96% up to 98% at 5 h incubation. For piperacillin/tazobactam, cefotaxime and meropenem, an accuracy of > more than 92% was achieved. The lowest concordance of 89 % was detected for fosfomycin.

Conclusions: The MBT FAST assay determined the susceptibility pattern towards those antibiotics most commonly applied against severe enterobacterial infections with a medium concordance of 92% compared to the reference method within 5 h incubation. The use of standardised hardware equipment further increased the performance compared to previous studies. An increase of the incubation time by only 30 min increased the validity and the accuracy of the assay.

Abstract 4576

A comparison of GenomEra GBS PCR and GeneXpert GBS PCR assays with culture of group B Streptococcus with and without broth enrichment

Stine Yde Nielsen*1, Jens Kjølseth Møller1, Mohammed Khalil2

1Vejle Hospital, Hospital Lillebælt, Clinical Microbiology, Vejle, Denmark, 2Kolding Hospital, Obstetrics and Gynecology, Kolding, Denmark

Background: Preventing neonatal infection with Group B streptococci (GBS) still receives substantial attention from researchers worldwide aiming at the ideal identification and prevention of transmission of GBS from mother to baby. Early-onset GBS disease (EOD) is still the most frequent cause of early-onset infection in neonates worldwide. More than 30% of infants delivered in the United States are now exposed to intrapartum antibiotics in order to prevent vertical transmission of GBS to the baby during their passage through the birth canal. This study was designed to compare the performance of GeneXpert® and GenomEra® GBS PCR assays, held up against gold standard of culture of GBS performed with and without broth enrichment.

Materials/methods: 366 women fulfilling one or more of the following criteria for presence of risk factors for EOD were prospectively included: (1) Bacteriuria during current pregnancy; (2) Prior infant with EOD; (3) Temperature above 38.0°C during labor; (4) preterm labor < 37 gestational weeks; (5) Rupture of membranes ≥18h.

Rectovaginal sampling was performed intrapartum and were immediately tested by GenomEra® CDX system (Abacus Diagnostica, Finland as well as by GeneXpert® (Cepheid Ltd., Sunnyvale, USA) as well as by standard culture with and without broth enrichment.

Results: In all, 366 pregnant women were tested intrapartum of which 99 had samples that were positive by culture, 95 by GenomEra and 95 by GeneXpert. When compared to culture, the GenomEra had sensitivity of 91.8% and the specificity of was 97.3%. The GeneXpert had sensitivity of 91.7% and a specificity of 96.9%. When compared to a combined reference standard the sensitivity increased to 91.9% and the specificity to 99.6% for GenomEra, and 91.9% and 98.8% for GeneXpert.

Conclusions: The performance of the two PCR methods examined, was very similar and very close to the findings in culture. GenomEra and GeneXpert have high sensitivities and PPV and are both applicable in a clinical setting.

Abstract 4577

Comparative evaluation of MAST Carba PAcE, RESIST-4 O.K.N.V. and NG-Test Carba 5 kits in the detection of carbapenemase production in clinical isolates

Jane Lee*1, Zahra Sadouki2, Indran Balakrishnan1,2, Emmanuel Wey1,2,3

1University College London, Gower Street, London, UK, University College London, London, United Kingdom, 2University College London, Gower Street, London, UK, Centre for Clinical Microbiology, Division of Infection & Immunity, London, United Kingdom, 3Royal Free London NHS Foundation Trust, London, United Kingdom

Abstract third-party references: Mast Group, Hardy Diagnostics

Background: Rapid detection of carbapenemases is crucial in informing both antimicrobial stewardship and infection control interventions. Here, we present a comparative evaluation of three carbapenemase detection kits in the detection of IMP-1, OXA-48, KPC, NDM-1, VIM-1 and VIM-2. The kits used are the colorimetric test MAST CARBA PAcE (Mast Group) and the immunochromatographic lateral flow assays RESIST-4 O.K.N.V. (Coris BioConcept) and NG-Test Carba 5 (Hardy Diagnostics).

Materials/methods: One hundred previously characterised clinical gram-negative isolates were evaluated using the three kits above. The prevalence of the various carbapenemase genes were: IMP-1 n=1, OXA-48 n=26, KPC n=5, NDM-1 n=24, VIM-1 & VIM-2 n=19, OXA-48 & NDM-1 n=4, others n=21.

Results:

</tbody>
</table>

Table 1: Comparison of the performance and costs of the three kits.

* The low specificity is due to many false positives, which can be related to detection of CTX-M-1 and ACT-1 and/or ACT-5 β-lactamases.

** Sensitivity of detection of NDM-1 (88.9%) and VIM (84.2%) was lower than that of IMP-1 (100%), OXA-48 (96.7%) and KPM (100%).

Conclusions: MAST CARBA PAcE kit is a relatively low-cost kit with high sensitivity for the detection of a broad range of carbapenemases, extending beyond the “big five”. However, it is unable to discriminate between the different genotypes. The more expensive lateral flow assays detect the “big five” carbapenemases with high sensitivity and specificity, with NG-Test Carba 5 being overall more sensitive and quicker than RESIST-4 O.K.N.V. These tests have the ability to distinguish between different genotypes, but their repertoire is limited to the “big five” carbapenemases.

Judicious diagnostic stewardship is essential in directing appropriate use of these kits in order to optimise their application in patient management. Whereas MAST CARBA PAcE has potential as a carbapenemase screening tool, the other 2 kits might be better suited to managing outbreaks involving the “big five” carbapenemases.

**Abstract 4592**

**Genotyping and antifungal susceptibility of *Candida albicans* isolates from vaginal samples: are the genotypes different from blood?**

Aina Mesquida*1;2, Judith Diaz-Garcia1;2, Teresa Vicente1, Elena Reigadas Ramirez1;2, María Palomo2, Patricia Muñoz1;2, Jesus Guinea Ortega1;2, Pilar Escribano1;2

1Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 2Gregorio Marañón Hospital, Madrid, Spain

**Background:** *C. albicans* is a common cause of vulvovaginal infection, frequently associated to relapses that may be due to acquisition of resistance to azoles. Furthermore, little is known about *C. albicans* clones potentially causing vulvovaginitis. We genotyped *C. albicans* isolates sourcing from vaginal samples and studied their antifungal susceptibility.

**Materials/methods:** Isolates from vulvovaginal samples isolated in the laboratory in 2017 were selected. Multiple *C. albicans* isolates from a single patient were further studied if separated in a period span over 1 month. Isolates, genotyped by species-specific microsatellite markers, were considered identical when showed the same alleles for all loci; clusters were identical genotypes found in ≥2 patients. Genotypes found were further compared with *C. albicans* genotypes sourcing from blood samples (n=1,134). Antifungal susceptibility to amphotericin B, fluconazole, voriconazole, posaconazole, micafungin, and anidulafungin was tested by EUCAST 7.3.1.

**Results:** We studied a total of 81 *C. albicans* isolates from 50 patients (n=29 patients with multiple isolates; 2-3 isolates per patient). From the 56 genotypes found, 53 (95%) were singleton and three were clusters (5%) that involved 8 out of the 50 patients. The majority of patients with multiple isolates [18/29, 62%] turned up with identical genotypes [5.5 months; 3-7 months] vs. the remaining 11 patients that harboured different genotypes [15 months; 9-18 months]. Singleton genotypes did not match with those from blood samples whereas the 3 clusters [5%] were further found in blood cultures; interestingly the three clusters were genotypes frequently found causing candidemia sometimes even in patients located at different hospitals. Fluconazole and posaconazole resistance was very low (2.4% of isolates from a patient); isolates were fully susceptible to the remainder drugs.

**Conclusions:** We found *C. albicans* genotypes from vulvovaginal samples rarely present in blood samples, suggesting proneness of some clones to cause vulvovaginitis. In patients with multiple isolates, isolates collected in short periods of time were identical genotypes (*P*<0.05). Furthermore, resistance to antifungal drugs was anecdotic.

Abstract 4596

**Linezolid resistance mechanisms in Staphylococcus capitis and Staphylococcus haemolyticus isolates collected in Gauteng, South Africa**

Karen L. Addison¹, Kathy-Anne Strydom¹, Ebrahim Hoosien², Yenga John Bolukaoto¹, Marleen Kock¹, Marthie M. Ehlers*¹

¹University of Pretoria, Pretoria, South Africa, ²Ampath Laboratories, Pretoria, South Africa

**Background:** *Staphylococcus capitis* and *Staphylococcus haemolyticus* are Gram-positive commensals that may cause hospital- and community-associated infections in the compromised host. The treatment of these infections with linezolid is being hampered by the emergence of resistance. Linezolid resistance is commonly mediated by chromosomal 23S rRNA gene mutations and plasmid-mediated chloramphenicol-florfenicol resistance (*cfr*) gene acquisition. In this study, investigation of these two linezolid resistance mechanisms was performed on *S. capitis* and *S. haemolyticus* isolates collected from private hospitals in Gauteng, South Africa.

**Materials/methods:** *Staphylococcus capitis* (n=43) and *S. haemolyticus* (n=9) blood culture isolates, processed using the BACT/ALERT® 3D (bioMérieux, France), were collected from 2016 to 2018. Inclusion criteria was linezolid resistance using the VITEK® 2 instrument (bioMérieux, France). Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectrometry (MS) identified the isolates. Linezolid susceptibility results were confirmed using ETEST® (bioMérieux, France). Multiplex polymerase chain reaction (M-PCR) assays confirmed species identification and a singleplex polymerase chain reaction (PCR) assay determined *cfr* gene presence. Pulsed-field gel electrophoresis (PFGE) was performed to determine genetic relatedness and representative isolates were selected for whole-genome sequencing (WGS).

**Results:** The *cfr* gene was not detected in the *S. capitis* or the *S. haemolyticus* isolates. The ETEST® (bioMérieux, France) *S. capitis* minimum inhibitory concentration (MIC) values ranged between 1.2 µg/mL and 12.8 µg/mL and the *S. haemolyticus* MIC values ranged between 8 µg/mL and 64 µg/mL. Three major clusters and four minor clusters were detected following PFGE of the *S. capitis* isolates, showing dissemination across numerous hospitals. The *S. haemolyticus* isolates displayed two minor clusters and one singleton. The WGS found various 23S rRNA gene mutations such as T2157A, C2190T, T2346C and G2603T in three representative *S. capitis* isolates.

**Conclusions:** The presence of 23S rRNA gene mutations in the absence of the *cfr* gene showed a high (24 µL/mL) MIC value, indicating that linezolid resistance is an emerging problem even when only one resistance mechanism is present. Therefore, the monitoring of linezolid resistance is needed in an effort to prevent widespread dissemination of resistance to linezolid.

Abstract 4597

**Active search through multiplex PCR method for sexually-transmitted infections in patients with sterile pyuria**

Helena Gil Campesino¹, Laura Sante*, Manuel Callejón Fernández¹, Enrique Callejas Castro², María Lecuona³

¹Hospital Universitario de Canarias, Cuesta (La, Spain, ²University of La Laguna, San Cristóbal de La Laguna, Spain

**Background:** Sterile pyuria is a highly prevalent condition. While bacterial infections of the genitourinary tract are the most frequent underlying pathologies, non-infectious causes and certain atypical microorganisms must also be taken into account, among which STIs are the most commonly related cause. The aim of this study was to investigate the prevalence of STIs: *C. trachomatis* (CT), *N. gonorrhoeae* (NG), *M. genitalium* (MG) and *T. vaginalis* (TV) among those patients with sterile pyuria as well as determine if the urine sample used previously for culture is valid for this determination.

**Materials/methods:** A PCR (Anyplex™ II STI-7 Detection, Seegene) was performed in the Hospital Universitario de Canarias Microbiology Service, on selected urine samples with sterile pyuria for patients between 18 and 55 years. Patient with recent episode of UTI were excluded. Epidemiological data was collected. In those patients of whom genital swabs or urine samples have been sent, a PCR was performed in parallel to compare results. All epidemiological and microbiological data was collected in an Excel table for further exploitation in the SPSS® Statistics program.

**Results:** During the period August-October 2019, 34% [206] of the sterile pyuria urine received in our Service met the criteria for inclusion; 193 woman (93.7%) of which 52 (27%) were pregnant, mean age 33.96±10.13. We obtained 15 (7.3%) positive results (Table 1), all of them were informed for subsequent clinical management. Two mixed infections were diagnosed: 1 CT with MG and 1 CT with NG. Analysed by sex: in the women’s group: 10 (5%) positive samples (4 (7.6%) in the pregnant group) and 5 (38.4%) positive in men’s group. 20 double samples were analyzed; of these, 19/20 were concordant (same result in both PCR). The calculated kappa coefficient was 0.44 (moderate force).

**Conclusions:** We found a non-negligible number of positives in a sample that a priori is not of choice for this diagnosis. Further studies will have to be carried out in the age groups between 18-34 years and in pregnant women to expand results and determine if the urine used for urine cultures is valid for determination of STIs.

Effect of *Bdellovibrio bacteriovorus* on clinical pathogens and biofilms

Selcan Kahraman¹, Yamac Tekintas²*, Feriha Cilli³, Mine Hosgor-Limoncu¹

¹Ege University, Faculty of Pharmacy, Department of Pharmaceutical Microbiology, Izmir, Turkey, ²Izmir Katip Çelebi University, Faculty of Pharmacy, Department of Pharmaceutical Microbiology, Izmir, Turkey, ³Ege University, Medical Faculty, Department of Medical Microbiology, Izmir, Turkey

**Background:** *Bdellovibrio bacteriovorus* is a Gram-negative obligate predatory bacterium which lives by attacking other bacteria including a very wide range of human pathogens. Here, we investigated the predatory behavior of *B. bacteriovorus* HD 100 ATCC 15356 against clinical Gram-positive (*Listeria monocytogenes* and *Staphylococcus epidermidis*) and Gram-negative (*Proteus mirabilis* and *Stenotrophomonas maltophilia*) isolates.

**Materials/methods:** Identification and antimicrobial susceptibility of the clinical isolates, isolated at Ege University Hospital Bacteriology Laboratory of Medical Microbiology Department were investigated and VITEK MS and VITEK 2 Compact® automated systems. The biofilm formations of the isolates were evaluated by crystal violet method in the presence and absence of *B. bacteriovorus* HD 100 ATCC 15356. Scanning electron microscopy was also used for monitoring the biofilms of isolates and predation *Bdellovibrio bacteriovorus*. All experiments were performed in triplicate.

**Results:** According to crystal violet method, all four clinical isolates had strong biofilm formation capacities. After predation of *B. bacteriovorus* biofilm formation capacities of isolates has been reduced (Table 1).

**Table 1. OD measurements of CV method**

**Conclusions:** Strong biofilm producer isolates has been detected in our hospital. Although *B. bacteriovorus* HD 100 ATCC 15356 has an inhibitory effect on biofilm formation of all clinical isolates, it reduced biofilm formation of Gram positive isolates (*L. monocytogenes* and *S. epidermidis*) more effectively. The study will be expanded with co-culture experiments and more clinical isolates.

Abstract 4602

Whole genome sequencing investigation into a single-site outbreak of NDM-mediated carbapenem resistance disseminated across multiple species predominantly via IncL/M plasmids

Nicholas Ellaby1, Jane Turton1, John Clark2, Anita Roche1, Rohini Manuel1, John Paul1, Bharat Patel1, Jayshree Dave1, Neil Woodford1; Matthew Ellington1

1Public Health England, London, United Kingdom, 2NHS, London, United Kingdom

Background: Mobile carbapenemase genes, including those of the NDM family, contribute to the increasing burden of carbapenem resistance. Plasmids encoding NDM can be highly mosaic, variable and difficult to track in large multi-species outbreaks. Using short- and long-read WGS we delineated discrete circulations of NDM-1 plasmids within a multi-species district-general hospital outbreak.

Materials/methods: Thirty-seven carbapenemase-producing isolates from 34 patients in a single hospital were submitted to PHE’s AMRHAI Reference Unit between July 2017-April 2018. MICs were determined by BSAC agar dilution methodology, interpreted with EUCAST guidelines, and isolates were short-read sequenced (illumina). Twelve genetically diverse isolates were selected for long-read sequencing (ONT). Bioinformatic tools were used on the hybrid assemblies to determine species, core genomes, resistance genes, plasmid replicons and STs. Bwa established best-fit references by mapping short-read sequences to hybrid assemblies.

Results: Thirty-four isolates of Enterobacterales (E. coli, E. cloacae, K. pneumoniae, K. oxytoca and Citrobacter) from distinct patients on 13 wards encoded NDM-1. There was little evidence of geo-temporal clustering of patients positive for clonal bactera. Nine isolates had NDM with IncF (n=4) or IncHI2 (n=5) plasmids. Twenty-five patients had IncLM NDM-1 plasmids temporally distributed across the outbreak.

IncLM-plasmid hybrid assemblies from six genetically diverse ‘outbreak’ isolates represented two variant plasmids IncLM-A and -B (86,615bp and 75,455, 87% nucleotide identity) with variable class-I integron sequence regions. Short-read mapping to the six reference assemblies revealed that these plasmids were dispersed across species; E. cloacae (IncLM-A n=6, IncLM-B n=4), E. coli (IncLM-A n=4, IncLM-B n=5), K. pneumoniae (IncLM-A n=3, IncLM-B n=1), and Citrobacter (IncLM-A, n=2).

IncLM-A and IncLM-B plasmids were first observed in weeks 2 and 8 respectively, with both being observed throughout the outbreak duration. Concurrent patients on two wards had either IncLM-A or IncLM-B plasmids. In three wards IncLM-A was observed exclusively. In one week, one ward had isolates from three species with IncLM-B. Long-read sequences indicated the migration of a NDM-1 integron from IncLM to F-/HI-2 type plasmids.

Conclusions: Long-read/short-read hybrid assemblies illuminated sub-circulations of mobile elements in a multi-species NDM-1 outbreak. Within this outbreak three additional levels of mobility were identified; plasmid-species transfer and integron/transposon-plasmid transfer.

Abstract 4606

Comparison of ResistancePlus MG and pyrosequencing for macrolide resistance detection in Mycoplasma genitalium and evaluation of macrolide and fluoroquinolone resistance in Badalona, Spain

Belen Rivaya Sanchez*1, Chloé Le Roy2, Gema Fernández Rivas1,3, Cristina Casan1, Victoria González1,4,5, Lurdes Matas Andreu1,3,5, Cécile Bébéar6, Sabine Pereyre7

1Hospital Universitari Germans Trias i Pujol, Servei de Microbiologia. Laboratori Clínic Metropolitana Nord, Badalona, Spain, 2University of Bordeaux, Department of Bacteriology, Bordeaux, France, 3Universitat Autònoma de Barcelona, Bellaterra, Spain, 4Centre d’Estudis Epidemiològics sobre el VIH/SIDA de Catalunya, Agència de Salut Pública de Catalunya, Generalitat de Catalunya, Badalona, Spain, 5CIBER in Epidemiology and Public Health (CIBERESP), Madrid, Spain, 6CHU de Bordeaux and Univ. Bordeaux, Department of Bacteriology, National Reference Center for bacterial STIs, Bordeaux, France, 7CHU de Bordeaux and Univ. Bordeaux, Department of Bacteriology, National Reference Center for bacterial STIs, Bordeaux, France

Abstract third-party references: Ayuda de la SEIMC

Background: Macrolides are the first-line treatment for Mycoplasma genitalium (MG) infections, but resistant patterns have been described. Fluoroquinolones are the second-line therapy. Consequently, the 2016 European guideline has recommended studying macrolide resistance-associated mutations in all cases where MG is detected. Several commercial kits have been released lately. Our aim was to compare the clinical performance of the ResistancePlus MG kit (SpeeDx, Australia) with our in-house methods. Additionally, macrolide and fluoroquinolone resistance prevalence was determined.

Materials/methods: A total of 100 MG-positive samples, collected at the Hospital Germans Trias y Pujol, Badalona, Spain, and previously tested for MG by real-time PCR (Allplex® STI-7, Seegene) and pyrosequencing (Pyromark®, Qiagen) to detect macrolide resistance were further analyzed using the one-step ResistancePlus MG kit (SpeeDx, Australia), and tested for fluoroquinolone resistance by parC gene Sanger sequencing at the University of Bordeaux, France.

Results: Regarding MG detection, an overall agreement of 87% was obtained comparing both methods. Thirteen samples were reported as negative by ResistancePlus MG but were detected with Allplex STI-7. Macrolide resistance prevalence was 64% in our hospital according to pyrosequencing. Among the 87 MG-positive samples detected using the ResistancePlus kit, 83 results were concordant with those obtained by pyrosequencing, showing an overall agreement of 95.4%. Three samples were reported as not mutated by the ResistancePlus kit but harbored a 23S rRNA A2058G (E.coli numbering) mutation by pyrosequencing, while the fourth sample was reported as mutated but was found wild-type by pyrosequencing.

Regarding fluoroquinolone resistance, 97 samples were wild-type for parC gene and 3 (3%) samples were resistant, harboring a S80I mutation (E. coli numbering). These three samples also harbored an A2059G macrolide resistance-associated mutation. Remarkably, one case corresponded to a second sample from a MG-positive patient that was initially found macrolide-resistant and fluoroquinolone-susceptible. After azithromycin and moxifloxacin treatment failures, the test-of-cure sample harbored both A2059G and S80I mutations.

Conclusions: The ResistancePlus MG SpeeDx is easy to use and showed a good correlation with pyrosequencing for mutation detection. Macrolide resistance is high in our area whereas fluoroquinolone resistance remains low. However, fluoroquinolone resistance should be studied in cases of moxifloxacin treatment failure.

A novel KPC-3 variant associated with CAZ/AVI resistance in an Klebsiella pneumoniae ST512 causing bacteraemia

Anna Knezevich1*, Marco Coppi2, Alberto Antonelli2, Vincenzo Di Pilato2, Tommaso Giani2,3, Stefano Di Bella4, Cristina Maurel4, Marta Zatta4, Sara Fossati4, Maria Teresa Bortolin1, Elena Piccoli1, Roberto Luzzati4, Gian M. Rossolini2,3, Marina Busetti1

1Azienda Sanitaria Universitaria Integrata di Trieste, Microbiology Unit, Trieste, Italy, 2University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 3Florence Careggi University Hospital, Clinical Microbiology and Virology Unit, Florence, Italy, 4Azienda Sanitaria Universitaria Integrata di Trieste, Infectious Diseases Ward, Trieste, Italy

**Background:** Ceftazidime-avibactam (CAZ/AVI) is a recent antibiotic which shows in vitro activity against many important Gram-negative pathogens including carbapenem-resistant Enterobacterales (CRE) producing KPC and OXA-48. Resistance to CAZ/AVI is still rarely reported, but poses a serious threat for the future. We report here the characterization of a CAZ/AVI-resistant Klebsiella pneumoniae strain carrying a novel KPC-3 variant.

**Materials/methods:** Identification was performed by VITEK® MS system (bioMérieux). Minimal inhibitory concentrations (MICs) were determined by a micro-dilution method (Sensititre Diagnostic System, Trek), and interpreted according to EUCAST clinical breakpoints v 9.0. A whole genome sequencing (WGS) approach (Illumina Miseq) was adopted to characterize the resistance mechanism to CAZ/AVI.

**Results:** A 78-year-old woman was admitted in hospital following a gluteal abscess post-arthroplasty treated with metronidazole and piperacillin/tazobactam, and developed a pneumonia caused by a KPC-producing K. pneumoniae, susceptible to CAZ/AVI. For this reason, the treatment was adjusted with CAZ/AVI in combination with tigecycline. However, a breakthrough bacteraemia occurred and a KPC-producing K. pneumoniae was isolated from blood cultures resulting resistant to CAZ/AVI (MIC >32 mg/L). A severe ischemia due to the occlusion of the iliac-femoral axis led the patient to a fatal outcome. WGS analysis showed that this isolate i) belonged to ST512, ii) had a bla_kp as the only carbapenemase gene, iii) presented a novel amino acid substitution (D179G), inside the omega-loop of KPC-3, previously associated with reduced susceptibility to CAZ/AVI as variant of KPC-2, iv) showed alterations in the outer membrane porins (OmpK35 and OmpK36).

**Conclusions:** CAZ/AVI resistance mechanisms has largely been attributed to nonsynonymous mutations in KPC-3. In this work, a CAZ/AVI resistant K. pneumoniae isolate with a new variant of KPC-3 was described after an initial treatment with this antibiotic, highlighting that a strict antibiotic-stewardship and infection control practices are necessary to preserve the drug efficacy of this recent drug.

Live probiotic vaccine against influenza virus infection

Tatiana Gupalova1, Yulia Desheva1, Galina Leontieva1, Eugenia Kuleshevich1, Tatiana Kramskaya1, Elena Bormotova1, Anna Tsapieva1, Alexander Suvorov*

1 Federal State Budgetary Research Institution "Institute of Experimental Medicine", Saint-Petersburg, Russian Federation

Background: Neuraminidase (NA) the second most important antigenic component of influenza virus. When the emergence of influenza viruses with a new subtype, antibodies to NA can play a decisive role in protecting against severe forms of infection until vaccination with a new antigenic variant is started.

Materials/methods: cDNA of influenza A17/duck/Potsdam/86/92[H5N2] virus was amplified by primers corresponding to the gene of neuraminidase [na]. Pneumococcal gene pspf was replaced by na in the integrative plasmid pent-pspf [Gupalova et al, 2019]. Resultant recombinant plasmid pent-na was isolated in the E.coli system and transformed into Enterococcus faecium L3 by electroporation. Location of the insert of the integrative plasmid in the chromosome was confirmed by PCR and DNA sequencing. CBA mice were orally immunized with a probiotic vector containing neuraminidase of subtype N2 [10 animals per group]. Blood serum was collected 4 days after the end of the second and third feeding cycles to determine IgG antibodies to NA subtype N. At 10 days after the end of the third vaccination, the mice were intranasally infected with 1 50% mouse lethal dose (MLD50) of pandemic influenza virus A/South Africa/3626/13(H1N1)pdm09.

Results: Chimeric construct with the genetic element NA for influenza vaccine was inserted in frame into enterococcal gene d2 by PCR. The resultant DNA ent-na, 1.8 kb in size was cloned in suicidal plasmid pT7ermB. An integrative plasmid was used for the electroporation of the enterococcal strain E. faecium L3. NA positive clone was selected and used in vaccine preparation for further immunization.

After the third oral immunization with E.faecium strain with na gene, serum IgG against whole A/H1N1 virus were detected. When immune mice were infected with a pandemic influenza virus, 67% of the animals were protected from mortality. The average weight of the mice treated with enterococcus without insertion was significantly less relatively to those immunized with enterococcus expressing NA.

Conclusions: Thus, oral immunization of mice with a probiotic vector containing NA of subtype N2 was shown not only to induce a virus-specific immune response, but also to provide partial protection from lethal infection with pandemic influenza virus A/South Africa/3626/13 [H1N1]pdm09.

Emergence of CTX-M-producing Salmonella enterica serotype Typhimurium in Greece

Efthymia Protonotariou1, Georgios Meletis1, Georgia Kagkalou1, Dimitra Papadopoulou1, Areti Tychala1,*, Fotini Netsika1, Olga Vasilaki1, Paraskevi Mantzana1, Melina Kachrimanidou1, Lemonia Skoura1

1AHEPA University Hospital, Department of Microbiology, Thessaloniki, Greece, 2Thessaloniki Psychiatric Hospital, Stavroupoli, Greece, 3Aristotle University of Thessaloniki, Medical School, Thessaloniki, Greece

Background: Salmonella infections are prevalent worldwide and are considered as the leading cause of foodborne hospitalizations posing a considerable financial burden on public health. Moreover, the emergence of drug-resistant strains restricts the available treatment options. We report here the emergence of three genetically related Salmonella isolates bearing CTX-M β-lactamases.

Materials/methods: The isolates were recovered from the feces of three infants of 16, 14 and 17-months hospitalized in the Pediatric ward of our hospital for mucus-bloody diarrhea. The first was admitted on September 2016 and the other two, two years later on September 2018. Species identification and susceptibility testing were performed by the VITEK2 system (bioMérieux) and by the disc-diffusion method. The antimicrobial susceptibility results were interpreted using the EUCAST breakpoints. Sero-typing was performed by the Greek National School of Public Health. The presence of β-lactamases was detected by PCR using specific primers for blaCTX-M, blaKPC, blaVIM, blAIM and blANDM. The clonal relatedness was assessed by ERIC II PCR.

Results: The isolates belonged to Salmonella enterica serotype Typhimurium and exhibited resistance or non-susceptibility to most β-lactams including cefotaxime and amoxicillin/clavulanate. They remained however susceptible to piperacillin/tazobactam, ceftazidime and carbapenems as well as to co-trimoxazole and fluoroquinolones. All three were positive for blaCTX-M and negative for carbapenemase-encoding genes. Their ERIC II patterns were similar suggesting that they were clonally related.

Conclusions: To the best of our knowledge, this is the first time Salmonella spp. harboring blaCTX-M is found in Greece. The emergence of such strains in pediatric patients is even more worrying since the treatment options for this patient group are already restricted and quinolones are ruled out a priori. Intensification of the infection control policies inside the hospital and especially in the Pediatric ward were suggested, because blaCTX-M are commonly carried on plasmids being thus able of horizontal gene transfer, not only among Salmonella spp. but also among other Enterobacterales in the hospital setting.

Abstract 4611

**Genetic diversity of *Pseudomonas aeruginosa* isolates colonising the lungs of cystic fibrosis patients at two academic hospitals in the Gauteng Province, South Africa**

Thabo Hamiwe*1, Robin Green2,3, Debbie White4,5, Lore Van Bruwaene4,6, Ameena Goga2,3, Marleen Kock1,7, Marthie M. Ehlers1,7

1University Of Pretoria, Pretoria, South Africa, 2Steve Biko Academic Hospital, Pretoria, South Africa, 3Univ of Pretoria - Medical Campus, Pretoria, South Africa, 4Charlotte Maxeke Johannesburg Academic Hospital, Johannesburg, South Africa, 5University of the Witwatersrand, Johannesburg, Johannesburg, South Africa, 6University of Pretoria, Pretoria, South Africa, 7National Health Laboratory Service - Tshwane Academic Division, Pretoria, South Africa

**Abstract third-party references:** Doctoral Research Bursary, University of Pretoria, South Africa, National Health Laboratory Service, Tshwane Academic Division, South Africa, National Research Foundation, South Africa

**Background:** The average life expectancy of a cystic fibrosis (CF) patient in South Africa is 20.5 years. A major point of health decline in these patients is the colonisation of their lungs with *Pseudomonas aeruginosa*. It is considered that CF patients are typically colonised with bacterial strains from their environment and patients sharing similar environments, such as those attending the same CF clinics are expected to be colonised with similar *P. aeruginosa* strains. Here, we used the enterobacterial repetitive intergenic consensus (ERIC)-PCR technique to determine the genetic diversity of *P. aeruginosa* strains colonising the lungs of CF patients at two academic hospitals in the Gauteng Province, South Africa.

**Materials/methods:** A total of 56 PCR identified *P. aeruginosa* were isolated from the sputum of seven *P. aeruginosa* colonised CF patients from the two academic hospitals. ERIC-PCR typing was performed on the isolates and the banding profiles were analysed using GelCompar II software (Applied Maths, Belgium). A Dendrogram clustering the isolates according to genetic relatedness was constructed using Dice co-efficient and unweighted pair group method with arithmetic mean (UPGMA).

**Results:** Cluster analysis results showed high diversity in the *P. aeruginosa* isolates among CF patients attending the same hospital. Some strains of *P. aeruginosa* were shared among patients attending the same clinic but the majority of the strains were unique to the individual patient. Limited inter-hospital spread was observed among the *P. aeruginosa* isolates. Within patient diversity was observed in three CF patients with some strains showing less than 50% similarity with the main cluster for that patient (Patients 2, 3, 4 and 6). Refer to the image below.

**Conclusions:** The majority of the CF patients in the study were colonised with multiple, genetically diverse strains of *P. aeruginosa*. Considering the impact *P. aeruginosa* colonisation has on patient health decline, genotypic characterisation is important to determine the diversity and spread of strains of this pathogen among CF patients. Further genomic sequencing of the *P. aeruginosa* strains is important to determine antibiotic resistance, virulence and sequence types.
Figure 1: ERIC-PCR typing cluster dendrogram showing genetic relatedness of the P. aeruginosa isolates from the study

**Abstract 4613**

**Evaluation of commercial media for susceptibility testing of Neisseria gonorrhoeae**

Leanne Davies1, Michelle Cole2, Carolyne Horner2, Fazila Ismail2, Zdravko Ivanov2, Helen Fifer2, Lim Jones1, Robin Howe1, Mandy Wootton*1

1University Hospital of Wales, Specialist Antimicrobial Chemotherapy Unit, Public Health Wales, Cardiff, United Kingdom, 2Public Health England, AMRSTI, London, United Kingdom, 3BSAC, Birmingham, United Kingdom

**Background:** There is currently no EUCAST disc diffusion method for susceptibility testing Neisseria gonorrhoeae (NG). For MIC determination, EUCAST recommends following manufacturers’ instructions along with EUCAST clinical breakpoints. Most laboratories will perform gradient strips, where the manufacturers’ media recommendations however these are not always available to routine laboratories and no Mueller Hinton (MH) Fastidious media has been shown to support good growth of NG. We have evaluated alternative commercially available media for quality of growth of NG and MIC results using the BioMerieux Etest gradient strips against the agar dilution (AD) reference method.

**Materials/methods:** Two sites, Specialist Antimicrobial Chemotherapy Unit [SACU] and AMRSTI [AntiMicrobial Resistance in STIs], Public Health England [PHE] performed the testing. Six media from three manufacturers: Oxoid GC + vitox (OxGC+V), Oxoid GC non-selective with lysed horse blood (OxGCNsel), Oxoid Chocolate with vitox (Oxch+V), Becton Dickenson GC chocolate (BDGCch), Becton Dickenson Mueller Hinton chocolate (BDMHch), E&O Mueller Hinton chocolate agar (E&OMHch) were evaluated. Quality of growth for 5 WHO strains and 5 clinical isolates “poor growers” was evaluated. MICs were determined on the same six media for 47 NG isolates and 2 WHO NG control strains using ceftriaxone and azithromycin Etests. Inocula were prepared using either saline or MH broth. MICs were compared to the AD reference method (GRASP surveillance study) using Diagnostic Sensitivity Test [DST] agar, 5% horse blood and 1% vitox.

**Results:** OxGC+V and BDGCch showed the best quality of growth. For MIC testing, percentage essential agreement can be seen below:

<table>
<thead>
<tr>
<th></th>
<th>Azithromycin</th>
<th>Ceftriaxone</th>

<td>100*</td>
</tr>
<tr>
<td>E&amp;OMHch</td>
<td>n/a*</td>
<td>78*</td>
</tr>
</tbody>
</table>

*Only data from SACU available

**Conclusions:** Two media (OxGC+V and BDGCch) performed best for quality of growth and showed comparable ceftriaxone and azithromycin MICs when compared with the reference method. The use of saline instead of recommended broth for inoculum preparation gave comparable results. Diagnostic laboratories can be assured that performing MICs on these media will produce accurate results.

**Presenter email address:** mandy.wootton@wales.nhs.uk
Transmission of Tn1721-like transposon harbouring CTX-M-27 between Salmonella and Escherichia coli isolates from food-producing animals in China

Qiu-Yun Zhao1, Yan Zhang2, Yuewei Lu2, Runmao Cai1, Hongxia Jiang*1

1South China Agricultural University, Guangdong Key Laboratory for Veterinary Drug Development and Safety Evaluation, Guangzhou, China, 2South China Agricultural University, Guangdong Key Laboratory for Veterinary Drug Development and Safety Evaluation, Guangzhou, China

Background: The aim of this study was to explore the characteristics of blaCTX-M-27 carriage and mobilization in Salmonella and Escherichia coli isolates from food-producing animals in China.

Materials/methods: A collection of 2280 E. coli and 355 Salmonella isolates from food animals between June 2003 and September 2014 in China were screened for the presence of blaCTX-M-27 genes. The blaCTX-M-27-positive isolates were characterized by replicon typing. blaCTX-M-27 harboring plasmids were sequenced to determine the genetic context of blaCTX-M-27.

Results: In total, 18 CTX-M-27-positive E. coli (0.79%) and 43 CTX-M-27-positive Salmonella (12.11%) were detected and all exhibited multidrug-resistant phenotypes. Replicon typing, S1-PFGE, and hybridization on CTX-M-27-carrying plasmids confirmed that blaCTX-M-27 gene was respectively located on IncFII (12/18), IncN (4/18), and non-typable (2/18) plasmids in E. coli, and IncP (6/43), IncFiB (4/43), IncN (2/43), IncHI2 (2/43), and IncA/C (1/43) plasmids in Salmonella. It worth noting that blaCTX-M-27 was captured by P1 bacteriophages (28/43) in the remaining Salmonella isolates. Comparison and analysis of the gene environment of blaCTX-M-27 in P1 like bacteriophage and plasmids discovered that they shared the same structure contained an identical genetic environment with Tn1721-like transposon (ΔISEcp1-blaCTX-M-27-IS9030-iroN-Δmap-Tn1721). Additionally, the fitness tests by growth and competition experiments proved that transformants carrying blaCTX-M-27 P1-like bacteriophage showed stronger viability than recipient bacteria without the pressure of cefotaxime.

Conclusions: Tn1721-like transposon harboring CTX-M-27 could mobilized between different replicon plasmids in E.coli, and could be integrated into P1 bacteriophage by which disseminated among Salmonella.

Presenter email address: hxjiang@scau.edu.cn
Clinical efficacy of ceftolozane-tazobactam versus other active agents for the treatment of bacteraemia and nosocomial pneumonia due to drug-resistant *Pseudomonas aeruginosa*

Matteo Bassetti1, Daniele Roberto Giacobbe1, Elena Rizzo2, Nadia Castaldo3, Cristina Mussini4, Anna Maria Cattelan5, Alessandro Russo6, Claudio M. Mastroianni7, Alessandro Capone8, Mario Tumbarello9, Antonio Vena1

1University of Genoa, Genoa, Italy, 2University of Udine, Udine, Italy, 3University of Udine, Infectious Diseases Division, Department of Medicine, University of Udine and Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy, Udine, Italy, 4University of Modena and Reggio Emilia, Modena, Italy, 5University of Padua, Padua, Italy, 6University of Pisa, Pisa, Italy, 7La sapienza university of Rome, Rome, Italy, 8Lazzaro Spallanzani Hospital, Roma, Italy, 9Università Cattolica del Sacro Cuore, Roma, Italy

Background: Ceftolozane/tazobactam (C/T) is a new cephalosporin with enhanced activity against *P. aeruginosa*, including multidrug (MDR) or extremely drug resistant (XDR) strains. Unfortunately, there are few data comparing outcomes of patients treated with C/T versus old regimens including polymyxins or aminoglycosides.

Materials/methods: We performed a retrospective multicenter 1:2 case-control study comparing patients with nosocomial pneumonia or bloodstream infection (BSI) due to MDR or XDR *P. aeruginosa* treated with ceftolozane-tazobactam or with either polymyxin or aminoglycoside-based regimens. Matching was based according to age (± 10 years), sex, type of infection and susceptibility profile of the isolated pathogen (MDR with MDR and XDR with XDR infections).

Results: Overall, 16 patients with MDR or XDR *P. aeruginosa* infections receiving an antibiotic regimen including ceftolozane-tazobactam were selected for the analysis. These patients were compared with 32 corresponding controls who received either a colistin-based (21, 43.8%) or aminoglycosides-based regimens (16, 33.3%). Mean age (±SD) was 62.4±14.5 years old and 81.3% of patients were males. Infection types were nosocomial pneumonia in 27/48 patients (56.3%) and bloodstream infection in the remaining 21/48 (43.7%). There were no significant differences between cohort in terms of demographics, main comorbidities and severity of disease. However, combination therapy was more commonly used in polymyxin/aminoglycosides patients than those who received ceftolozane/tazobactam (90.6% vs 56.3%, P = 0.01). Clinical cure at day 14 was higher (81.3% versus 56.3%, P = 0.11) and thirty-day mortality lower among cases (18.8% versus 28.1%; P = 0.72), but differences did not reach statistical significance. Polymyxin/aminoglycosides regimens were associated with increased rates of acute kidney injury (25.0% vs 0% P = 0.04).

Conclusions: Ceftolozane-tazobactam was well tolerated and at least as effective as other alternatives for *P. aeruginosa* infections. Our data support its preferential use for treatment of MDR or XDR *P. aeruginosa* infections.

Abstract 4620

The application of CRISPR/Cas9-based genome editing in knocking out the blaNDM-1 gene to study the mechanisms of pandrug resistance in clinical isolates

Xiao Yu*, Yonghong Xiao

1First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, 2the First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: The development of antibiotic resistance in bacteria is a major public health threat. Infection rates of resistant pathogens continue to rise against nearly all antimicrobials, which has led to development of different strategies to combat the antimicrobial resistance. Recently, the clustered regularly interspaced short palindromic repeats (CRISPR)-associated protein 9 (CRISPR/Cas9) system has been applied to combat antibiotic-resistant bacteria.

Materials/methods: Plasmid pcas9 expressing Cas9 was constructed and used to clone target single-guide RNAs (sgRNAs) for knocking out the blaNDM-1 gene. The recombinant plasmid pcas9-sgRNA was transfered by electroporated at 1.8 kV, 200 Ω into three clinical isolates (2 Klebsiella oxytoca and 1 Escherichia coli). The knocking out efficiency of sgRNAs targeting conserved genes was tested. S1-PFGE was used to evaluated the difference between parent plasmids and the mutant plasmids. Furthermore, we also investigated the plasmids recombination by nanopore sequencing.

Results: The deletion of blaNDM-1 gene in three clinical isolates were successfully constructed with efficiency over 90%. In this study, we observed the 4 plasmids fused into 3 plasmids in the E.coli mutant, while in two Klebsiella oxytoca mutant, the size of plasmids which original carrying blaNDM-1 gene reduced 100k and 10k, respectively. Moreover, sequencing results revealed that different transposons, insertion sequences, and recombination sites increased the variability of knockout results.

Conclusions: CRISPR/Cas9 can be used to efficiently sensitize clinical isolates to carbapenem in vitro. For isolates with multiple plasmids, the CRISPR/Cas9 approach can cause plasmid recombination. Moreover, this approach can be used to delete the mobile elements containing the resistance gene by using only one sgRNA. However, caution must be exercised to avoid unwanted recombination events during genetic manipulation. There is still challenge to practice these methods in field against emerging antimicrobial resistant pathogens.

Evaluation of a highly specific sample-to-result real-time PCR assay for detection and typing of *Bordetella pertussis*, *Bordetella parapertussis* and *Bordetella holmesii* in nasopharyngeal aspirates, nasopharyngeal swabs and sputum samples

Giulia Linardos¹, Gabriella Ricciotti¹, Livia Piccioni¹, Carlo Concato*¹

¹Bambino Gesù Children’s Hospital, IRCCS, UOC Microbiology, Virology and Parasitology, Rome, Italy

**Background:** Whooping cough is a worldwide infectious disease occurring after transmission of the bacteria from person-to-person in airborne droplets caused by *Bordetella pertussis* (BP), *Bordetella parapertussis* (BPP) and *Bordetella holmesii* (BH). Despite of vaccination, incidence reported is increasing in Europe, with severe consequences in children under five. Pertussis diagnosis is mostly done using molecular methods, but the detection of multiple targets is essential to differentiate *Bordetella* spp. This study describes the performance of the multiplex Real-Time PCR assay “Bordetella ELItE MGB® Kit” in association with ELItE InGenius® instrument, the first fully automated sample-to-result solution, for highly sensitive BP, BPP and BH detection and typing, in nasopharyngeal aspirates, nasopharyngeal swab and sputum.

**Materials/methods:** The performance evaluation studies on Bordetella ELItE MGB® Kit were carried out in association with ELItE InGenius® instrument. The diagnostic validation studies were performed by Bambino Gesù Children’s Hospital, IRCCS (Rome, Italy) after ethic committee approval on 30 positive samples and 30 negative samples of nasopharyngeal aspirates, nasopharyngeal swab and sputum. Sample analysis is on-going.

**Results:** Bordetella ELItE MGB® Kit preliminary LoD ranged between 12 and 45 CFU / mL depending on the pathogen. Inclusivity was verified on 11 different strains and cross-reactivity on 18 different pathogens of respiratory tract. Test with “QCMD 2016 Bordetella pertussis EOA Panel” (Qnostics) allowed the correct detection and identification of all species including BH typing. The preliminary diagnostic specificity was 95% in respiratory sample. The preliminary diagnostic sensitivity was tested by analyzing IS481 positive samples and resulted 100%. Furthermore, the assay allowed the differentiation of one BH positive sample. The turnaround-time was about 150 minutes.

**Conclusions:** Bordetella ELItE MGB® Kit in association with ELItE InGenius instrument constitutes a highly specific and sensitive system for rapid detection and typing of BP, BPP and BH in one single PCR reaction. This innovative solution overcomes limitations of culture and serological methods for the diagnosis of Bordetella infection and simplifies the laboratory workflow by reducing testing turnaround time from days to hours.

Meta-analysis of accuracy of rapid influenza antigen detection tests in community-care settings accounting for antigen type, setting, population and manufacturer

Elisa Gentilotti1, Eleonora Cremonini1, Pasquale De Nardo1, Anna Gorska1, Fulvia Mazzaferr1, Mical Paul2, Herman Goossens3, Evelina Tacconelli1

1University of Verona, Infectious Diseases Unit, Department of Diagnostics and Public Health, Verona, Italy, 2Rambam Health Care Campus, Division of Infectious Diseases, Haifa, Israel, 3University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Diseases Institute, Antwerpen, Belgium

Abstract third-party references: This work has received support from the EU/EFPIA/bioMérieux SA, Janssen Pharmaceutica NV, Accelerate Diagnostics S.L., Bio-Rad Laboratories, BD Switzerland Sarl, and The Wellcome Trust Limited. Innovative Medicines Initiative 2 Joint Undertaking VALUE-Dx grant n° 820755.

Background: Evidence on the performance of point-of-care rapid influenza antigen detection tests (RIADTs) is essential to inform public health and antibiotic policy interventions. As part of the VALUE-Dx Project, we performed a systematic review and meta-analysis to determine the diagnostic accuracy of RIADTs in community-care settings.

Materials/methods: Multiple electronic databases were searched to identify published studies assessing the diagnostic accuracy of immunochromatographic RIADTs for influenza A and B virus in patients presenting with influenza-like illness at a community-care settings including primary care (PC), outpatient clinic (OC), long-term care facility (LTFC), and emergency room (ER). Viral culture and/or PCR were considered as reference standard. A bivariate random-effects model and hierarchical summary receiver-operating characteristic (HSROC) were used to estimate the pooled accuracy for influenza. Subgroup analyses were conducted by antigen type, age group, study year, WHO region, and commercial kits.

Results: After titles/abstracts screening and full-text eligibility assessment, 40 articles reporting 84 studies (56, 67% assessing influenza A and 28, 33% B) in 19,790 patients were included. The majority of studies were performed in the ER (47, 56%). No study was run in LTFCs neither tested influenza B in PC. Sensitivity ranged from 0.24 [0.17; 0.33] to 1.00 [0.91; 1.00] for influenza A and from 0.22 [0.12; 0.36] to 0.97 [0.93; 0.99] for influenza B. Specificity ranged from 0.76 [0.63; 0.87] to 1.00 [0.98; 1.00] for influenza A and from 0.90 [0.85; 0.93] to 1.00 [0.99; 1.00] for influenza B. The pooled sensitivity and specificity were 0.66 [0.59; 0.72] and 0.99 [0.99; 1.00] for influenza A and 0.53 [0.41; 0.65] and 0.99 [0.99; 1.00] for influenza B. Setting and commercial kits were the most relevant sources of heterogeneity as detailed in table.

Conclusions: RIADTs in community-care settings showed high specificity and considerable variability in sensitivity by setting and commercial kits. The pooled sensitivity seems slightly better for the detection of influenza A rather than B. These results seem to suggest that inclusion of RIADTs in clinical algorithms in community-care settings during the influenza season should consider sources of heterogeneity for appropriate cost effectiveness analyses and inclusion in stewardship interventions.

Table. Subgroup analysis.

Abstract 4629

**Surface ocular microbiome in dry eye syndrome: a preliminary study**

Claudio Foschi¹, Piera Versura², Clarissa Consolandi³, Marco Severgnini³, Maria Carla Re¹, Antonella Marangoni*¹

¹University of Bologna, DIME, Microbiology, Bologna, Italy, ²University of Bologna, DIME, Ophthalmology, Bologna, Italy, ³National Research Council, Institute of Biomedical Technologies, Segrate, Milan, Italy

**Background:** Dry eye syndrome (DED) has become the most common ocular surface disease throughout the world. Dry eye is a multifactorial condition of the tear and ocular surface that results in symptoms of discomfort, visual disturbance, and tear film instability with potential damages to the eye. The bacterial composition of the ocular surface (microbiome) has been considered among the components involved in the pathogenesis of DED. In this explorative study, we assessed the composition of the surface ocular microbiome in patients with DED, comparing the traditional culture-based techniques with new genomic approaches.

**Materials/methods:** Five lower conjunctiva swabs (E-swab, Copan) were obtained from as many patients with DED. The patients attended the Outpatient Clinic of Ophthalmology of S. Orsola-Malpighi University Hospital in Bologna (Italy) and were subdivided in two groups, on the basis of clinical signs and symptoms: moderate dryness (n=3) and severe dryness (n=2). Swabs were cultured in different solid media and grown bacterial colonies were identified by means of MALDI-TOF mass spectrometry. In parallel, ocular samples were subjected to nucleic acid extraction for amplification and sequencing of V3-V4 regions of bacterial 16s rRNA gene. Obtained reads were filtered and clustered into Operational Taxonomic Unit (OTUs) at 97% identity level. Taxonomic assignment was performed via the RDP classifier against the Greengenes database.

**Results:** By means of 16s rRNA gene sequencing, the microbial composition of the ocular surface proved to be rich in different bacterial genera, including several anaerobes, with a significant diversity between subjects. Lactobacillus, Corynebacterium and Staphylococcus genera accounted for 20-50% of all the microorganisms detected. Patients with severe dryness were characterized by significantly higher levels of Propionibacterium compared to subjects with moderate dryness (p=0.03). With the conventional culture-based approach, only a few bacterial genera were recovered, especially staphylococci and corynebactria.

**Conclusions:** The surface ocular microbiome in patients with DED is characterized by a high diversity in the bacterial composition, being enriched in anaerobic bacteria. 16s rRNA gene sequencing is far more sensitive than traditional culture-based methods in revealing the complexity of the ocular environment.

Epidemiology and dissemination of multidrug-resistant *Pseudomonas aeruginosa* colonisation in an intensive care unit

Maria Eugenia Portillo*¹, Joaquín Lobo², Amaya Bacaicoa², Jesús Oteo³, Ana Navascués Ortega¹, Carmen Ezpeleta Baquedano¹

¹Complejo Hospitalario de Navarra, Instituto de Investigación Sanitaria de Navarra (IdisNA), Pamplona, Spain, ²Complejo Hospitalario de Navarra, Pamplona, Spain, ³Instituto de Salud Carlos III, Madrid, Spain

**Background:** Multidrug resistant *Pseudomonas aeruginosa* (MDRPA) is an emerging problem due to the global spread of defined high-risk clones. ST175 is associated with serotype O4 and 2 MALDI-TOF peaks and its underlying resistance mechanism is mostly mutational. We aimed to study the epidemiology of ICU patients who acquired MDRPA in order to develop specific control strategies.

**Materials/methods:** Patients admitted to the ICU at the Complejo Hospitalario de Navarra from January to November 2019 had weekly perianal culture samples collected. Swab samples from the ICU tap drains were collected for the detection of carbapenemase-producing strains. We defined: a) admission-positive patients when had positive cultures at ICU admission for MDRPA; b) acquisition-positive patients when had negative cultures at ICU admission but a subsequent positive culture for MDRPA; and c) endogenous microbiota when had susceptible *P. aeruginosa* at ICU admission but a subsequent MDRPA with identical PFGE patterns was detected. We characterized the resistance mechanisms by molecular PCRs. We characterized MDRPA strains by PFGE, MLST, serotyping and MALDI-TOF biomarker peaks.

**Results:** Our cohort consisted of 1867 perirectal swabs with 255 isolated *P. aeruginosa*, of which 64 (25%) were MDRPA. MDRPA were isolated in 23 patients. 2 patients were admission-positive and 21 patients were acquisition-positive MDRPA. Among the acquired MDRPA, 4 (19%) were acquired by the patients' endogenous microbiota and 17 (81%) during their stay at ICU. ST175 was the main clone detected among the 14 patients with acquired MDRPA. We detected a VIM-2 carbapenemase cluster among 2 patients and 1 tap drain samples and another VIM-2 carbapenemase cluster among 1 patient and 3 tap drain samples.

**Conclusions:** Most of MDRPA at ICU were acquired. Though cross-transmission plays the main role in MDRPA acquisition in our ICU, we cannot define them as patient-to-patient transmission without excluding an undiscovered reservoir. In fact, in 3 (14%) patients the VIM transmission was through tap drains. Therefore, it is important to implement active surveillance of MDRPA clones. Serotyping and MALDI-TOF are useful tools for early detection of ST175. In order to avoid possible outbreak sources, surveillance measures to minimize the dissemination and cleaning of environmental foci should be implemented.

Abstract 4633

No attributable mortality due to third generation cephalosporin resistance but common risk factors for mortality in patients with infections due to Enterobacteriaceae

Jiancong Wang*1,2, Mouqing Zhou3, Julien Sauser1, Walter Zingg1

1Infection Control Program and WHO Collaborating Centre on Patient Safety, University of Geneva Hospitals and Faculty of Medicine, Geneva, Switzerland, 2University of Geneva, Institute of Global Health, Geneva, Switzerland, 3Dong Guan Nosocomial Infection Control and Quality Improvement Centre, Dongguan, China

Background: Third-generation cephalosporin (3GC)-resistance in enterobacteriaceae (3GCRE) challenges antimicrobial stewardship and is a potential threat to patient safety. There is no data on infections due to 3GCRE on mortality in Mainland China. This study aimed at estimating attributable mortality from infections due to 3GCRE compared to 3GC susceptible enterobacteriaceae (3GCSE) in Dongguan City, 2017.

Materials/methods: We retrospectively analyzed data of patients from three tertiary-care hospitals with infections due to both 3GCRE and 3GCSE. We measured time-to-event from first infection until discharge, either all-cause mortality or discharge/transfer. Hospitalizations were censored at 30 days. A multivariate Cox proportional-hazards model was applied to estimate the effect of 3GCRE on all-cause mortality, adjusting for the following variables: age, gender, department type, bloodstream infection (BSI), seasons, and length of stay (LOS).

Results: 1667 patients with infections due to enterobacteriaceae were eligible for analysis, including 573 3GCRE patients and 1094 3GCSE patients, respectively. Among these, 49% (278/573) 3GCRE and 42% (460/1,094) 3GCSE patients were hospitalized in surgery; and 46% (262/573) 3GCRE and 43% (465/1,094) 3GCSE patients had a urinary tract infection. The proportion of 3GCRE was statistically significantly higher in patients with healthcare-associated infections compared to patients with community-acquired infections (P=0.009). All-cause mortality was 2% in both groups. There was no statistically significant difference in the multivariate survival analysis between the two groups (HR, 0.8; 95%CI, 0.4-1.6). However, gender (HR, 2.7; 95%CI, 1.4-5.2), BSI due to enterobacteriaceae (HR, 3.2; 95%CI, 1.5-6.8), and LOS >15 days (HR, 4.3; 95%CI, 1.6-11.5) were independently associated with all-cause mortality.

Conclusions: No attributable mortality from 3GCR was found. Actionable risk factors such as BSI and prolonged LOS were also identified in patients undergoing infections due to enterobacteriaceae.

Background: Streptococcus agalactiae (GBS) is an important pathogen with a wide host range, causing sepsis and meningitis in humans, mastitis in cattle and streptococcosis in fish. This results in much medical and veterinary morbidities and a huge economic burden to both livestock and aquaculture industries worldwide. The outbreak of adult sepsis due to consumption of raw fish with serotype III, ST283 in Singapore establishes the zoonotic nature of GBS disease. We sought to identify strain clusters that have interspecies association by comparing genomes of GBS strains isolated from human and animal hosts, and to phenotypically characterize fitness and virulence of these strains in a murine infection model.

Materials/methods: Phylogenetic relationship among 828 non-duplicate strains with whole genome data available from the public domains, including sequencing of 249 GBS strains in this study, was analysed. A phylogenetic tree inferred from core genome alignments was produced using Roary and sequence types (STs) identified and linked on goeBURST. The fitness of GBS strains was examined by their generation time at 37 °C and 39 °C, and virulence evaluated in ICR 6-wk old mice inoculated with 10^7 cfu intraperitoneally and survival monitored for 10 days. ATCC12403 [ST23 serotype III] was included as control.

Results: Closely related strains between human and animal hosts were identified in three major clusters within CC103, CC283 and CC1 suggesting possible cross-species transmission. GBS strains implicated were CC103 (ST103, sLV ST651 from humans and cows); CC283 (ST283, sLV ST491 in humans and fishes); CC1 (ST1 and sLV ST2 in humans, cows, rodents). The mean generation times (n=25) of the CC strains ranged 43.1±10.0 to 71.8±2.4 min (individual strains ranging 35 – 86 min). Strains of CC1 (ST1 and 2) gave the shortest mean generation times at both temperatures as compared to CC103 and CC283 [p<0.001]. Murine infection model revealed 90% mortality with ST283 vs 0% in other ST types [p<0.01].

Conclusions: Evidence from comparative genomic analyses reveal interspecies transmission between human and animal GBS in three major clonal clusters; CC103, CC283 and CC1. GBS shows a wide variation in generation time, with CC1 revealing its fitness while CC283 remains most pathogenic among these clusters.

Impact of rapid molecular detection of sepsis on time to optimal antimicrobial therapy in paediatric cancer patients at the National Cancer Institute, Egypt

Hadir El-Mahallawy1, Emad Ebeid1, Safaa Hassan1, Farida Naguib1, Reham Khedr*2,3

1Cairo University, National Cancer Institute, Cairo, Egypt, 2Children’s Cancer Hospital Egypt 57357, Cairo, Egypt, 3National Cancer Institute - Cairo University, Cairo, Egypt

Background: The clinical microbiology laboratory plays a key role in the diagnosis of bloodstream infections (BSI). Reducing the time to microorganism identification and susceptibility is crucial to improving clinical outcome and subsequently reducing length of hospital stay and associated costs.

Materials/methods: This study was conducted at National Cancer Institute (NCI) on 120 pediatric cancer patients suspected to have sepsis according to a revised consensus conference definition in 2016 (Sepsis 3). Samples were sent to the microbiology laboratory during one year extending from December 2017 to December 2018. They were divided into two groups, group I to whom only blood cultures were done (n=60); while in group II, blood cultures and rapid molecular method for detection of sepsis were done (n=60). The test used was the hospital acquired infection real-time multiplex-PCR detection kit; which detects 21 different bacterial pathogens directly from venous blood sample. Bactec 9120 and Vitek-2 (Biomerieux, France) were used for the conventional blood culture testing.

Results: Compared to the conventional approach, using the rapid multiplex-PCR detection kit showed a significantly shorter turnaround time to identification. The median turnaround time for group I blood culture was 120 hrs with IQR (96-144 hrs) compared to 5 hrs with IQR (4-6 hrs) for (p value <0.001). Shift to optimal antimicrobial therapy was effectively achieved in 75% of patients in Group II compared to 48% of cases in group I (p value 0.003). All-cause mortality was lower in the multiplex-PCR group but the difference was not statistically significant (42% versus 50%, p = 0.360). There was agreement between the results of the multiplex-PCR detection kit and blood culture in 93.3% of isolates. Four isolates were detected only by the multiplex-PCR.

Conclusions: Sepsis is a time-dependent disease that requires early diagnosis and prompt appropriate treatment to improve prognosis. The benefits of rapid diagnosis of sepsis etiology are earlier adequate antimicrobial treatment and reduction of duration of hospital stay and mortality.

Presenter email address: riham.abdelaziz@57357.com
**Abstract 4637**

**Evaluation of the performance of CSF pyrosequencing in the diagnosis of TB meningitis - a single-centre retrospective diagnostic accuracy study**

Kanchan Ajbani1, Mubin Kazi1, Umang Agrawal1*, Rajeev Soman1, Anjali Shetty1, Ayesha Sunavala1, Camilla Rodrigues1

1PD Hinduja National Hospital and MRC, Mumbai, India

**Background:** We evaluated the performance of pyrosequencing, a rapid genotypic test which detects TB and resistance to isoniazid, ethionamide, rifampicin, aminoglycosides and fluoroquinolones in 6 hours, directly on the CSF samples in the diagnosis of TB meningitis.

**Materials/methods:** This retrospective study was conducted in a tertiary care hospital in Mumbai from May 2017 to May 2019. 101 consecutive patients with physician suspected TB meningitis for whom CSF pyrosequencing was requested were studied. 1 patient with incomplete data was excluded. Lancet consensus case definition criteria were applied to classify patients into the following categories: Definite, Probable, Possible and Alternative diagnosis. Those with Definite TB meningitis were considered to have the disease, while those with alternative diagnosis were considered to not have the disease. Sensitivity, specificity, positive predictive value and negative predictive value of pyrosequencing was determined. The sensitivity of pyrosequencing was compared to MGIT culture and Xpert MTB Rif using chi square test. Statistical results were interpreted at 5% significance. Susceptibility concordance rate of pyrosequencing with MGIT culture DST and Xpert MTB Rif were determined.

**Results:** The study cohort comprised of 100 patients [Definite (n=33), Probable(n=20), Possible(n=30) and Alternative(n=17)] with 50% males [median age: 38 years (Range, 2-87 years)]. The sensitivity, specificity, positive predictive value and negative predictive value of CSF pyrosequencing to diagnose TB meningitis was 96.7%, 100%, 100% and 94.4% respectively. This test had a higher sensitivity [statistically insignificant] compared to Gene Xpert (96.7% vs 69.6%, p=0.12) and TBMGIT (96.7% vs 70%, p=0.16). This test was positive in all patients with probable meningitis, 95% (n=19/20) of whom showed good clinical response to treatment. Susceptibility concordance rate of pyrosequencing with MGIT culture DST(n=21/23) was 91.3% and with Xpert MTB Rif (n=22/23) was 95.6%.

**Conclusions:** CSF pyrosequencing facilitates early therapeutic decision making by confirming the diagnosis of TB meningitis and providing information on the mutations of the XDR-defining drugs, within 6 hours of the sample being collected. It is more sensitive than Xpert MTB Rif and MGIT culture and may be useful in cases where both these investigations test negative in true cases of TB meningitis.

**Presenter email address:** drumangagrawal87@gmail.com
Activity of enmetazobactam in combination with cefepime in a murine urinary tract infection model challenged with an ESBL-producing isolate of Escherichia coli

Carina Vingsbo Lundberg1, Adam C Belley2, Philipp Knechtle*2

1Statens Serum Institut, København S, Denmark, 2Allecr Therapeutics, Saint-Louis, France

Background: Infections caused by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae account for more than 20'000 deaths every year in the EU and US alone. Enmetazobactam (EMT) is a novel β-lactamase inhibitor belonging to the penicillanic acid sulfone class, targeting ESBLs. Enmetazobactam, in combination with cefepime (FEP), is currently being investigated in a Phase 3 randomized controlled trial in patients with complicated urinary tract infections or acute pyelonephritis. This study investigated the efficacy of FEP-EMT in a murine urinary tract infection model challenged with a cefepime-resistant, ESBL-producing isolate of Escherichia coli.

Materials/methods: C3H/HeJ mice carrying a spontaneous mutation in the Tlr4 gene at the lipopolysaccharide response locus rendering this strain highly susceptible to infections by Gram-negative bacteria were used in this study. Animals were infected with a bacterial suspension inserted via the urethra into the bladder. Treatment started 24 h post infection by subcutaneous administration of test article on a q8h schedule for two days. Bacterial burden was determined 48 h post infection in kidneys by quantitative agar plating. MICs were determined by broth microdilution with EMT at a fixed concentration of 8 µg/ml.

Results: Broth microdilution assays identified FEP and FEP-EMT MICs of >32 and 0.05 µg/ml for the CTX-M-15-producing E. coli isolate #2014-0032. This strain demonstrated a robust infection in kidney with a 1-log10 increase in bioburden within 48 h compared to pre-treatment. FEP at 10 mg/kg administered q8h reduced kidney bioburden by 0.3 log10 units compared to pre-treatment. EMT administered at ≥1 mg/kg q8h, in combination with FEP at 10 mg/kg q8h, reduced kidney bioburden by 2.0 log10 units compared to pre-treatment, which was comparable to meropenem (MEM) administered at 20 mg/kg q8h (Figure).

Conclusions: Enmetazobactam restores the efficacy of cefepime in a urinary tract infection model challenged with a cefepime-resistant, ESBL-producing isolate of E. coli. Cefepime-enmetazobactam may qualify as novel empiric carbapenem-sparing option for the treatment of serious Gram-negative infections in settings where ESBL-producers are suspected and/or prevalent.

Comparable resistance levels between regional networks in the Netherlands
Wieke Altorf - Van Der Kuil*, Annelot Schoffelen1, Damian Melles2, Sabine C. De Greeff1
1Centre for Infectious Diseases, Department for Epidemiology and Surveillance, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 2Department of Medical Microbiology and Immunology, Meander MC, Amersfoort, Netherlands

Background: In 2016 the Dutch Ministry of Health, Welfare and Sport requested the formation of ten regional cooperative networks. The aim is to improve the collaboration between healthcare providers and healthcare facilities in order to prevent development and spread of antimicrobial resistance on a regional level. To identify targets for interventions, insight in the resistance at regional level is necessary.

Materials/methods: We used Dutch routine medical microbiological data from the Dutch national surveillance system for antimicrobial resistance (ISIS-AR). Data of general practitioners’ patients from 34 laboratories from which data were available for the full period from 2014 to 2018 were included. We calculated resistance percentages in diagnostic urinary isolates of E. coli (n=437338) and K. pneumoniae (n=52352) for co-amoxiclav, cefotaxime/ceftriaxone/ceftazidime, ciprofloxacin, fosfomycin, trimethoprim, co-trimoxazole, and nitrofurantoin. In diagnostic wound, pus, and skin isolates of S. aureus (n=20345) we calculated resistance levels for flucloxacillin (i.e. MRSA) and clindamycin. We investigated whether resistance levels within the regions showed a significant (p<0.05) and clinically relevant difference with the mean resistance in all regions combined for at least three years. Clinical relevance was defined based on expert opinion as a difference that was larger than the square root of the national resistance percentage.

Results: Resistance levels in E. coli for all agents were not different between regions. For K. pneumoniae we found a three year lower resistance only for fosfomycin in Noord-Brabant in the years 2015 (22 versus 31% in all regions combined), 2016 (14 versus 31%), and 2017 (15 versus 26%). For S. aureus only resistance to clindamycin was higher for three years in the region Noord-Holland West; 18 versus 8% in 2014, 15 versus 9% in 2016, and 18 versus 11% in 2018.

Conclusions: As expected, since the Netherlands is a small country and national treatment guidelines are used widely, we did not find regional variation for most of the investigated organism-antimicrobial agent combinations. The few observed differences may be a result of sampling policy or population factors for which no data are available in ISIS-AR, like use of antimicrobials or foreign travel. This needs further investigation within the regions.

Abstracts 2020

Abstract 4642

Mapping the implementation of a clinical pharmacist-driven antimicrobial stewardship programme at a tertiary care centre in India

Vrinda Nampoothiri*, Sangita Sudhir1, Mariam Varsha1, Zubair Mohamed1, Vidya Menon1, Esmita Charani3, Sanjeev Singh1

1Amrita Vishwa Vidyapeetham, Amrita Institute of Medical Sciences, Kochi, India, 2Lincoln Medical Center, New York, United States, 3Imperial College London, Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, London, United Kingdom

Background: Evidence from many settings including the UK and USA supports the role of clinical pharmacists as integral part of antimicrobial stewardship programmes (ASP). However, in many parts of the world, including in India pharmacist roles in ASP remain unexplored. We describe the evolution and effect of the role of adding clinical pharmacists to a multidisciplinary ASP at a tertiary care teaching hospital in Kerala, India.

Materials/methods: Under the championship of the hospital medical superintendent a multidisciplinary ASP Committee including hospitalist, microbiologist and intensivist was established in February 2016. A bespoke training programme (including a 2-month rotation in the ASP Committee) was created by the ASP clinicians for Doctor of Pharmacy interns. The responsibilities assigned to the clinical pharmacists included: 1) review of antimicrobial prescriptions for appropriateness [right indication, right drug, right dose, right frequency and right duration]; 2) surveillance of reserved antimicrobials; 3) providing teaching and training on ASP; 4) lead ASP quality improvement initiatives (fig1). Inappropriate prescriptions were identified, presented, discussed at the ASP Committee and the recommendation was fed back to the clinical teams verbally and in written format by the clinical pharmacists.

Results: Results discussed are between February 2016 and February 2019. Out of 1326 prescriptions reviewed in the first year 56% (742/1326) were appropriate and 54% (318/584) were compliant with ASP recommendations. By third year of ASP implementation, appropriateness and compliance to recommendations increased to 80% (1752/2190) and 70% (227/325) respectively. The Anti tubercular therapy (ATT) stewardship implemented subsequently in June 2017 reviewed 157 prescriptions within a year, of which 61% (95/157) were appropriate and 42% (25/60) recommendations showed compliance. From June 2018 to February 2019, 72% (62/86) ATT prescriptions were appropriate and 58% (14/24) were compliant with ATT recommendations.

Conclusions: A clinical pharmacist driven ASP can be effective in implementing sustainable change in low- and middle-income countries (LMIC) such as India where the shortage of Infectious Diseases physicians’ specialty is a major impediment to ASP. The multidisciplinary model in this hospital has potential for scale up to other hospitals in India and LMIC.

Fig 1: Timeline showing the evolution of clinical pharmacist role in ASP

Laboratory-confirmed influenza infection and acute myocardial infarction

Yinong Young-Xu1, Jeremy Smith*1, Salaheddin Mahmud2, Ellyn Russo1, Rob Van Aalst1, Edward Thommes3, Jason Lee3, Ayman Chit3

1VA Medical Center, White River Junction, United States, 2University of Manitoba, Winnipeg, Canada, 3Sanofi Pasteur, Swiftwater, United States

Abstract third-party references: Sanofi Pasteur

Background: Previous studies established an association between laboratory-confirmed influenza infection (LCI) and hospitalization for acute myocardial infarction (AMI). However, they did not focus on the elderly population, and lacked detailed laboratory measures.

Materials/methods: We used a self-controlled case-series design to evaluate the effect of LCI on hospitalization for AMI among Veterans Health Administration (VHA) patients. We included elderly Veterans (age ≥ 65 years) with LCI between 2010 through 2015. Patient-level data from VHA electronic medical records were used to capture laboratory results, hospitalizations, and baseline patient characteristics. Centers for Medicare and Medicaid Services fee-for-service files were used to capture hospitalizations that occurred at non-VHA facilities. Our analysis included laboratory test results on inflammation - white blood cells count (WBC), platelet activation - platelet count (PLT), age, and concurrent diagnosis of pneumonia. We defined the "risk interval" as the first 7 days after respiratory specimen collection, and the "control interval" as 1 year before and 1 year after the risk interval.

Results: We identified 391 hospitalizations for AMI that occurred within 1 year before and 1 year after a positive test result for influenza, of which 31 (31.1 admissions per week) occurred during the risk interval and 360 (3.5 admissions per week) occurred during the control interval. The incidence ratio of an admission for AMI during the risk interval compared to the control interval was 8.9 (95% confidence interval [CI], 6.2 to 12.8). No increased incidence was observed after day 7. In the subgroup analyses, risk for AMI was elevated among those with age above the median (75) at 11.9 (95% CI, 7.6-18.7), high WBC at 12.4 (95% CI, 7.0-22.1), and high PLT at 15.9 (95% CI, 3.6-70.4). Patients with a concurrent diagnosis of pneumonia had similar risk compared to those without at 8.4 (95% CI, 2.6-27.2).

Conclusions: We confirmed a significant association between LCI and AMI. The risk was elevated among patients of older age, those with high WBC or high PLT, suggesting a potential role for inflammation and platelet activation in the underlying mechanism.

Abstract 4645

**Presence of multidrug-resistant bacteria on uniforms of healthcare professionals in healthcare settings in Cyprus: implications for targeted infection control interventions**

Pavlina Lena1,Spyridon Karageorgos2,Dimitris Lamnisos1,Panos Papageorgis1,Constantinos Tsioutis*2

1European University Cyprus, School of Sciences, Egkomi, Cyprus,2European University Cyprus, School of Medicine, Egkomi, Cyprus

**Background:** Multidrug-resistant bacteria (MDRB) constitute one of the most important issues in public health and their transmission within healthcare settings is a significant hazard for patients. To this end, healthcare professionals’ clothing has been shown to harbor pathogens that may contribute in increasing the risk of transmission. The aim of this study was to evaluate the presence of MDRB on HCP uniforms in Nicosia, Cyprus.

**Materials/methods:** Randomized, cross-sectional sampling of consenting HCP uniforms in 9 hospital wards and 7 long-term care facilities (LTCFs) in Nicosia, Cyprus, between April-August 2019. Sampling was conducted using sterile swabs pre-moistened in MRD (maximum recovery diluent), close to the end of the first shift, from both left and right pocket. Following enrichment in Brain Heart Infusion broth and overnight incubation at 37°C, isolated strains were identified and screened via standard microbiological methods; sensitivity testing was performed using the VITEK 2 system (bioMérieux). Personal hygiene and other habits recorded during interviews with HCP.

**Results:** Among 140 sampled HCP (69 from hospitals, 71 from LTCFs), a total of 33 MDRB were identified [Table]. Presence of MDRB was higher in LTCFs [n=22] compared to hospitals [n=11] [p=0.04]. No significant differences were found in years of experience or self-reported habits between HCP in hospitals and LTCF, such as hand hygiene frequency, place or frequency of uniform laundering, or visits to other wards.

**Conclusions:** In this study, we showed that HCP uniforms harbor MDRB and constitute a target for intervention to reduce the risk of MDRB transmission in Cyprus. We identified LTCFs as an important area for application of infection control measures, to reduce the burden of MDRB. Additional factors that could influence the presence of MDRB on HCP uniforms should be sought, in order to delineate further areas that could benefit from infection control.

Chikungunya positive reference material based on lentiviral vector system for RT-qPCR assays

Cristina Escolar1*, Silvia Valledor2,3, Elena De Tomas Mateo3

1University of Zaragoza, Zaragoza, Spain, 2University of Zaragoza, Faculty of Science, Zaragoza, Spain, 3CerTest Biotec S.L., San Mateo de Gállego, Spain

**Background:** We use the lentiviral vector system to produce RNA positive reference materials for *in vitro* diagnostic assays. These materials solve the problem of many RT-qPCR assays in which the retrotranscription step is not evaluated, since the positive control is frequently a synthetic cDNA sequence. These novel controls allow us to evaluate the whole process, from nucleic acid extraction to PCR reaction. We report here the method for generation a positive reference material for Chikungunya virus, an emerging tropical RNA virus that should be handled under biosafety level 3 conditions. This non-infectious positive control, that mimic the wildtype virus, constitutes an endless source of Chikungunya positive sample and its management does not require any specific security measure.

**Materials/methods:** Lentiviral particles were generated by transfection of HEK 293T cells using second generation lentiviral system with lipid-based reagent FuGENE6. We also performed transfection without envelope vector as a method to increase the biosafety of the process, and we analyzed the effect on transfection efficiency. The transference vector contains fragments of the NS1, NS2, NS4, E3 and E1 genes of the Chikungunya genome, which are the most frequently used targets in qPCR assays. Supernatant was harvested at 48- and 72-hours post-transfection, centrifuged and filtered. Then it was extracted with the QIAamp Viral RNA Kit (Qiagen) and subsequently treated with DNase to remove residual plasmid DNA. The extracted RNA was amplified and quantified with “VIASURE Chikungunya Real Time PCR Detection Kit (Certest Biotec)”.

**Results:** The target concentration of the enveloped virus was 1,16E+10 copies/ml and 4,50E+09 copies/ml for supernatants collected at 48h and 72h, respectively. In the non-enveloped virus, the target concentration was 1,26E+10 copies/ml and 6,24E+09 copies/ml, respectively.

**Conclusions:** We have generated a replication defective and non-infectious positive control of Chikungunya virus to monitor the whole process of nucleic acid extraction and PCR. This control contributes to improve the diagnostic accuracy of the qPCR assays. We have also demonstrated that transfecting without the envelope vector does not affect the viral particle production. This standardized and optimized lentiviral system allows to create custom viral particles for a wide variety of pathogens.

Abstract 4648

The dissemination and molecular characterisation of clonal complex 361 methicillin-resistant Staphylococcus aureus in Kuwait hospitals, 2016-2018

Edet Udo1, Eiman Sarkhoo*,1, Samar Boswihi1, Elke Müller2, Stefan Monecke3, Ralf Ehricht4

1Department of Microbiology, Faculty of Medicine, Jabriya, Kuwait, 2InfectoGnostics Research Campus Jena, Jena, Germany, 3Leibniz Institute of Photonic Technology (IPHT), Jena, Jena, Germany, 4 Friedrich Schiller University Jena; Institute of Physical Chemistry, Jena, Germany

Background: Methicillin-resistant Staphylococcus aureus (MRSA) continues to pose serious problems among patients globally and in the Gulf Cooperation countries. Since being first identified in two patients’ samples in 2010, the prevalence of CC361-MRSA obtained from patients in Kuwait hospitals has increased significantly. The aim of this study was to determine the molecular characteristics of CC361-MRSA isolated from patients in Kuwait hospitals between 2016 and 2018 to understand its population dynamics

Materials/methods: Of 6945 MRSA isolates obtained from 2016-2018, 182 (2.6%) were identified as CC361-MRSA isolates by DNA microarray analysis. These isolates, obtained in 2016 [N=55], 2017 [N=56] and 2018 [N=71], from different clinical samples in 13 Kuwait hospitals were further analyzed using antibiogram and spa typing.

Results: Most of the isolates were from nasal (N=63) and skin and soft tissue infection samples (N=33). They were resistant to fusidic acid, trimethoprim and ciprofloxacin and harbored fusC and dfrS1. The isolates belonged to 22 spa types with t13841 (N=113), t315 (N=16), t1309 (N=14) and t1375 (N=5) comprising 81.3% of the spa types. The CC361-MRSA consisted of four genotypes [strain types] including CC361-MRSA-[V/VT+fus] (N=112), CC361-MRSA-V, WA MRSA-29 (N=36), CC361-MRSA-V, WA MRSA-70/110 (N=33) and CC361-MRSA-[V+fus] variant (N=1). All CC361-MRSA isolates were positive for capB, agr1, and the enterotoxin egc gene cluster (seg, sei, selm, seln, selo, selu) while, tst-1 was detected in 22 isolates only. The immune evasion cluster (IEC) genes type B (scn, cph, sak) and type E (scn, sok) were detected in 19 and 150 isolates respectively.

Conclusions: The study has provided evidence of an ongoing transmission of a newly emerged CC361 MRSA strains with CC361-MRSA-[V/VT+fus] as the dominant genotype. The dissemination of this clone can impose different challenges for control and treatment of MRSA infections in Kuwait hospitals. Therefore, understanding the MRSA population dynamics might contribute to the development of effective approaches to control this important pathogen.

Abstract 4651

Different age distribution of influenza B virus infection by lineage
Ye Jin Kim¹, Seung Beom Han*¹, Kyung-Yil Lee²

¹College of Medicine, The Catholic University of Korea, Seoul, South Korea

Background: Determining the age-specific distribution of influenza B virus infection can be helpful for establishing an infection control and prevention strategy for influenza virus, including a proper use of a tetravalent influenza vaccine.

Materials/methods: Between the 2015-2016 and 2018-2019 influenza seasons, rapid influenza diagnostic tests were performed in 13,853 patients, and 3,437 (24.8%) of them were positive for influenza viruses. Excluding 94 patients with concomitant influenza A and B virus infection, the remaining 3,343 patients (influenza A infection in 2,223 [66.5%] and influenza B virus infection in 1,120 [33.5%]) were included in this study, and their medical records were retrospectively reviewed. The median ages were compared between patients with influenza A virus infection and those with influenza B virus infection.

Results: As a whole, the median age of patients with influenza B virus infection was significantly lower than that of patients with influenza A virus infection (8 years vs 13 years, \(P<0.001\)). In influenza seasons when influenza B/Victoria lineage was dominant, the median age of patients with influenza B virus infection was still significantly lower than that of patients with influenza A virus infection (6 years vs 11 years, \(P<0.001\)). In seasons when influenza B/Yamagata lineage was dominant, the median age of patients with influenza B virus infection was not significantly different from that of patients with influenza A virus infection (14 years vs 27 years, \(P=0.155\)), but significantly higher than that of patients with influenza B virus infection in seasons when influenza B/Victoria lineage was dominant (14 years vs 6 years, \(P<0.001\)).

Conclusions: The different age distribution of influenza B virus infection by lineage seems to be resulted from different virological characteristics and infectivity of two influenza B virus lineages according to the host’s age.

Abstract 4656

Paving the way for the implementation of a decision support system for antimicrobial prescribing in primary care in West Africa: a workshop with healthcare professionals

Nathan Peiffer-Smadja*1;2;3, Armel Poda4, Abdou Salam Ouedraogo4, Jean-Baptiste Guiard-Schmid6, Tristan Delory5, Josselin Le Bel5, Pauline Jeanmougin5, Elisabeth Bouvet2;5, Sylvie Lariven2;5, Raheelah Ahmad1, Xavier Lescure2;3;5

1Imperial College London, Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, London, United Kingdom, 2Bichat-Claude Bernard Hospital, Department of Infectious Diseases, Paris, France, 3Inserm, Infection Antimicrobials Modelling Evolution, Paris, France, 4Institut Supérieur des Sciences de la Santé, Université Nazi Boni, Bobo-Dioulasso, Burkina Faso, 5Antibioclic Steering Committee, Paris, France

Abstract third-party references: Supported by Antibioclic

Background: Clinical decision support systems (CDSS) for antimicrobial prescribing have been devised to provide the prescriber with rapid access to updated information. In low- and middle-income countries, introduction of CDSS for antimicrobial prescribing could have measurable impact. However, pre-implementation research is needed to ensure that CDSS are adapted to the context in which they are deployed and are adopted in routine clinical care.

Materials/methods: Our objective was to study the requirements for a CDSS for antimicrobial prescribing in primary care adapted to the context of West Africa and to analyse the barriers and facilitators to its use. We aimed to discuss the expected consequences and potential risks of implementing a CDSS and to co-design solutions.

Results: There were 47 participants in the workshop, 19 women and 38 men representing 9 West African countries and 6 medical specialties. Most of the participants had access to a smartphone during consultation (n=35, 74%) but only 49% had access to a computer and none used a CDSS for antimicrobial prescribing. The participants considered that a CDSS could have positive consequences such as improving clinical care and reducing AMR, updating the knowledge of practitioners on antimicrobial prescribing, encouraging the development of national guidelines and developing surveillance capabilities in primary care. The CDSS should be tailored to the local epidemiology of infectious diseases and AMR and to the availability of diagnostic tests and antimicrobials using national guidelines where available. A procedure of co-design with health professionals involved in antibiotic prescribing including nurses, midwives and pharmacists was encouraged. The participants suggested to first implement the CDSS in a pilot site and to disseminate the tool using traditional professional networks and social media. The lack of widespread internet access and computers could be circumvented by the development of a mobile application with an offline mode. The participants pointed the risk of self-medication in West Africa where antibiotics can be bought with no prescription and underlined the need to regulate access to antibiotics.

Conclusions: Our study provided valuable information to develop and successfully implement a CDSS for antimicrobial prescribing among primary care prescribers in LMICs.

Abstract 4657

**Performance of the Xpert Carba-R assay versus the ChromID CARBA SMART for the detection of carbapenemase-producing Gram-negative bacteria from rectal swabs**

Shawn Vasoo*1, Charlene Kang1, Pei Yun Hon1, Weihua Lin1, Janice Wai Yeng Leong2, Janis Wan Ning Loh2, Weixiang Lian2, Adriana Soo Hui Tan1, Tan Sun1, Jia Qi Kum2, Bee Fong Poh2, Shehara Mendis2, Pooja Rao2, Angela Chow1, Goh Tek Ng3, Kalisvar Marimuthu1, Brenda Ang1, Partha Pratim De2

1National Centre for Infectious Diseases (NCID), Singapore, Singapore, 2Tan Tock Seng Hospital, Singapore, Singapore, 3National Healthcare Group Pte Ltd (NHG HQ), Singapore, Singapore

**Abstract third-party references:** Supported by a Health Services Development Grant (19N01) from the Ministry of Health, Singapore

**Background:** Direct-from-sample real-time PCR assays allow rapid detection of carbapenemase-producing Gram-negative bacilli (CPGNB), but are limited by targets included in the assay. Culture-based methods are mechanism-agnostic, but require confirmatory testing for carbapenemase-production, and have longer turn-around-times. We evaluated the Xpert Carba-R real-time PCR assay and the ChromID CARBA SMART chromogenic agar (followed by the carbapenem-inactivation method (CIM) / conventional PCR) in parallel for the detection of CPGNB.

**Materials/methods:** From April-September 2019, 15,843 surveillance rectal swabs (ESwab, Copan) were submitted for CPGNB screening. Swabs were subject to the Carba-R assay (which detects \( \text{bla}^{KPC} \), \( \text{bla}^{NDM} \), \( \text{bla}^{OXA-48-\text{like}} \), \( \text{bla}^{IMP} \), and \( \text{bla}^{VIM} \)), and ESwab liquid Amies media was cultured on each side of the ChromID biplate. GNB isolated on ChromID were subject to MALDI-TOF MS, susceptibility testing (Vitek). Enterobacteriales (carbapenem non-susceptible) were subject to an in-house conventional PCR for \( \text{bla}^{KPC} \), \( \text{bla}^{NDM} \), \( \text{bla}^{OXA-48-\text{like}} \), \( \text{bla}^{IMI} \) and \( \text{bla}^{IMP} \) test. All meropenem-resistant non-fermenting GNB were subject to the mCIM/CIM-Tris test. Two different ‘gold-standards’ [GS] were evaluated: “GS1”: One where a true positive was considered as any sample with a positive Xpert result OR a positive ChromID result (defined as an Enterobacteriales with a carbapenemase confirmed by conventional PCR); “GS2”: Which in addition to the definition of GS1, incorporated a positive mCIM/CIM-Tris test for non-fermenting GNB as a true positive.

**Results:** A total of 432 (2.7%) of samples were positive for CPGNB (122 OXA-48 type, 94 NDM, 51 IMP, 14 IMI, 9 KPC, 18 multiple genotypes, 107 positive mCIM/CIM-Tris); 338 (46.1%) were Enterobacteriales, 283 (38.6%) were non-fermenters, 112 (15.3%) were PCR-positive only. The sensitivity of Carba-R and ChromID, based on the two gold standards GS1 and GS2 were as follows:

<table>
<thead>
<tr>
<th></th>
<th>GS1 (95% CI)</th>
<th>GS2 (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Sensitivity</strong></td>
<td><strong>Specificity</strong></td>
<td><strong>Sensitivity</strong></td>
</tr>
<tr>
<td>Carba-R</td>
<td>92.3 (88.7-94.8)</td>
<td>100 (98.8-100)</td>
</tr>
<tr>
<td>ChromID</td>
<td>42.2 (36.8-47.7)</td>
<td>100 (98.8-100)</td>
</tr>
</tbody>
</table>

**Conclusions:** The Carba-R assay was found to be more sensitive than a culture-based algorithm. However, the specific gold standard used can affect the interpretation of test performance. Specifically, algorithms which omit phenotypic testing for carbapenemase production or screening of non-fermenting GNB (obtained on culture) will underestimate the true magnitude of CPGNB in one’s institution.

**Presenter email address:** shawn_vasoo@ttsh.com.sg
Abstract 4659

CRISPR/Cas9 targeting of essential herpes simplex virus type 1 genes impairs virus replication in the mammalian cell

Natalia Demidova*, Regina Klimova1, Dmitry Karpov2, Alla Kushch1

1Ivanovsky Institute of Virology, Gamaleya National Center of Epidemiology and Microbiology, Moscow, Russian Federation, 2Engelhardt Institute of Molecular Biology, Moscow, Russian Federation

Background: Herpes simplex virus type 1 (HSV-1) is a widespread human virus. According to the WHO, the virus infects nearly 67% of world’s population. In the majority of primarily infected individuals HSV-1 becomes latent and resistant to all antiviral drugs. Moreover, new drug-resistant HSV strains have emerged, which urges the search for new therapeutic strategies. Genome editing technology using CRISPR/Cas9 system has been proposed as one of the perspective approaches. CRISPR/Cas9 system expressed from lentiviral vectors effectively suppresses HSV infection in a cell model. However, safety issues can arise from integrative mutagenesis of lentiviral vectors and accumulation of mutations associated with a long-term action of permanently active CRISPR/Cas9 system. In addition, cell protection against HSV provided by lentivirus-expressed CRISPR/Cas9 is lost after 24 h. This instigates further search for other effective and safe vectors and means of CRISPR/Cas9 targeting. Our goal was to evaluate the ability of CRISPR/Cas9 expressed from plasmids targeted at various HSV-1 genes to suppress HSV-1 infection in cells.

Materials/methods: The following CRISPR/Cas9 plasmids were used: empty PX458 vector coding for SpCas9 and structural fragment of sgRNA, and the vector derivatives with cloned spacers against ICP0, UL8, UL29 and UL52 HSV-1 genes. The plasmids were transfected into Vero cells using Lipofectamin 3000, and cytotoxicity was assessed by MTT assay. Then transfected cells were infected with HSV-1 and quantified by immunocytochemical staining using an anti-gB monoclonal antibody.

Results: Transfection with CRISPR/Cas9 plasmids has shown high effectiveness (>50%) in Vero cells with low cytotoxicity (>70% live cells in transfected population). Plasmids encoding for a single spacer against dispensable ICP0 gene did not inhibit HSV-1 infection in Vero cells, while plasmids encoding for two spacers and targeting CRISPR/Cas9 system at HSV-1 replication complex genes (UL8-UL29 and UL52-UL29) decreased the percentage of infected cells up to 16.5-25%. One of the plasmids targeted at UL52-UL29 genes provided a 100% inhibition of HSV-1 infection for 48 h and up to 6 days.

Conclusions: The results obtained indicate that plasmid-expressed CRISPR/Cas9 system is a perspective candidate for the development of new therapeutic strategies to combat herpesviral infections.

Presentation, outcomes and relapse rate of patients admitted with Plasmodium vivax malaria in Karachi, Pakistan

Faisal Mahmood*, Marium Hashmi1, Rida Ahmad1, Shahira Shahid1, Aneera Ahmed1, Safia Awan1

1Aga Khan University Hospital, Pakistan, Karachi, Pakistan

Background: Plasmodium vivax is the most geographically widespread species of malaria, with most cases originating from India, Pakistan, and Indonesia. There has been an increase in the severity and the number of P. vivax malaria cases in Pakistan. Moreover, relapse rates in this part of the world may vary from the South East Asian and African strains of P. vivax. We, therefore, performed a cross sectional study of patients admitted with P. vivax malaria to assess the severity of disease, outcomes and relapse rates.

Materials/methods: A retrospective cross-sectional study at a 700-bedded tertiary care hospital in Karachi, Pakistan was performed. Case files of all adults admitted with P. vivax malaria [on smear or ICT], between 2007-2016 were reviewed. Patients with co-infection with P. falciparum were excluded from the study. Severity based on the WHO definitions, treatment strategies and inpatient outcomes were assessed. Patients were contacted after discharge to assess if a relapse had occurred.

Results: A total of 539 admissions in 522 patients were assessed. Most admissions occurred between August and September (34.8%). Males were more likely to be admitted (M:F ratio 349:189) and the average age was 40.7 years. A total of 168 cases (31.2%) were assessed to have severe malaria with an overall mortality of 1.5% (n=8). High dependency care [HDU] was required by 110 patients (20.4%). The most common markers of severity were hemoglobinuria, renal failure, jaundice, acidosis and bleeding. Compared with those without severe malaria, patients with severe malaria were more likely to have diarrhea, be admitted to the HDU and had a higher mortality. Of the survivors, there were 95 patients with relapses (18.2%) of which 16 (16.8%) required readmissions.

Conclusions: Severe malaria was not uncommon in P. vivax malaria admitted to a tertiary care hospital in Karachi Pakistan and was associated with increased mortality and requirement for high dependency care

**An outbreak of hepatitis A among young adult men in Cyprus**

Panagiotis Dimitriou¹, Christina Flourou¹, Georgios Nikolopoulos², Maria Koliou²,³, Elisavet Constantinou¹, Chara Azina¹, Maria Panagiotou¹, Eirini Christaki*¹,²

¹Department of Medicine Nicosia General Hospital, Nicosia, Cyprus, ²Medical School, University of Cyprus, Nicosia, Cyprus, ³Ministry of Health, Unit of Surveillance and Control of Communicable Diseases, Nicosia, Cyprus

**Background:** Outbreaks of Acute Hepatitis A (AHA) have recently been reported in Europe among men who have sex with men (MSM). Clinicians of our team observed a notable increase in hospitalized AHA cases in Cyprus, during the second semester of 2017. The aim of this work was to evaluate, for the first time, trends in the reported cases of AHA in Cyprus over the last six years.

**Materials/methods:** We retrospectively studied all people reported with AHA to the Unit for Surveillance and Control of Communicable diseases of the Cyprus Ministry of Health between January 2013 and December 2018. Demographic data, type of transmission, vaccination status for HAV, laboratory and clinical data were analyzed.

**Results:** The analysis involved 33 AHA cases (age 32.7 ±17.4 years, 78.8% males). An increase in AHA reports was observed between July 2017 and June 2018 when more than a third (n=13) of the cases of the period 2013-2018 were reported. The distribution of the 33 cases in the six-year period, is presented in Figure 1. The cases reported between July 2017 and June 2018 were young men and four identified themselves as MSM. The reporting rate of AHA doubled from 0.52 cases per 100,000 population (before July 2017) to 1.12 cases per 100,000 population (July 2017-June 2018). The male/female (M/F) ratio increased from 1 in 2013 to 8 in 2018. All patients were negative for HIV infection by serology and one was diagnosed with syphilis at the same time. One patient with AHA during the first semester of 2017, just before the outbreak, was taking pre-exposure prophylaxis. One patient, who was simultaneously diagnosed with chronic hepatitis B, developed fulminant hepatic failure and had a successful liver transplantation. Another patient, with history of obesity, developed fulminant hepatitis A and died.

**Conclusions:** An increase in AHA reports occurred in Cyprus between July 2017 and June 2018. Many cases with AHA in that period were MSM. Enhanced surveillance of cases with AHA and timely public health interventions, like vaccination and awareness promotion, are important for preventing future outbreaks.

Characterisation of Neisseria gonorrhoeae isolates using a core-genome multilocus sequence typing scheme

Paul G. Higgins*1,2, Julia Wille3, Harald Seifert3

1German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 2University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 3University of Cologne, Inst. Medical Microbiology, Immunology and Hygiene, Cologne, Germany

Background: Recent reports point to a dramatic increase in antibiotic-resistant Neisseria gonorrhoeae (NGO), but there are scarce data regarding NGO in Germany. We investigated the antimicrobial susceptibility and molecular epidemiology of NGO using a core-genome MLST (cgMLST) scheme on isolates from patients with symptoms of urethritis reporting to the University of Cologne between 11/2015 - 11/2019.

Materials/methods: In total, seventy-seven isolates were collected. Susceptibilities to azithromycin, cefotaxime, ciprofloxacin, penicillin, and tetracycline were determined by Etest. Molecular epidemiology was investigated using an ad-hoc cgMLST scheme based on 1567 alleles (Ridom® SeqSphere+). Genome sequences were queried for antibiotic resistance genes and to determine 7-loci MLST.

Results: Seventeen isolates were fully susceptible to all the antibiotics tested. Non-susceptibility based on EUCAST breakpoints (ECOFF of 1mg/L for azithromycin) was; cefotaxime (n=4), azithromycin (n=6), tetracycline (n=27), ciprofloxacin (n=45), and penicillin (n=46). Twenty-two isolates were non-susceptible to 1 antibiotic, thirteen were non-susceptible to 2 antibiotics, and twenty-five were non-susceptible to ≥ 3 antimicrobials, and we consider them to be multidrug resistant (MDR). At least one antibiotic retained activity against each isolate. Tetracycline MICs ≥ 8mg/L were associated with tetM-like. Ciprofloxacin resistance was associated with GyrA substitutions. blaTEM-1 and penA variants were detected in many isolates, but this was not always associated with penicillin or cefotaxime resistance, or elevated beta-lactam MICs. Seven-loci MLST revealed 21 sequence types (ST), two of which were represented by 11 isolates; ST-7363 and ST-8156. cgMLST delineated isolates further, and split ST-7363 into two separate clusters separated by 730-753 allelic differences. Generally there were several hundred alleles different between STs, but there are exceptions, with as low as 14 alleles different between STs, highlighting the limitations of 7-loci typing. We detected nine possible transmission clusters involving 2-4 patients where isolates were separated by ≤ 10 allelic differences, including four clusters with ≤ 2 differences.

Conclusions: cgMLST allowed us to differentiate between isolates with the same ST. We detected nine potential transmission events. Almost one third of isolates were MDR, with five of the transmission events involving these MDR isolates. Cefotaxime retained good activity against N. gonorrhoeae from the Cologne area.

Evaluation of the potential clinical impact of BioFire FilmArray Pneumo Plus for the treatment of VAP in intensive care unit patients, Careggi University Hospital, Florence

Bruno Viaggi1, Eleonora Riccobono2*, Matteo Bendinelli1, Valeria Zucchelli3, Tommaso Giani2,4, Gian M. Rossolini2,4

1Careggi University Hospital, Department of Anesthesiology, Neuro Intensive Care Unit, Florence, Italy, 2University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 3bioMerieux Italia, Florence, Italy, 4Careggi University Hospital, Clinical Microbiology and Virology Unit, Florence, Italy

Background: Ventilator-associated pneumonia (VAP) is the most frequent nosocomial infection in ICUs, accounting for almost 50% of all antibiotic prescriptions. The administration of inappropriate initial antibiotic therapy is associated with greater mortality and longer hospital stay. More precise and rapid microbiologic diagnostic approaches for suspected VAP are urgently needed to guide optimal therapeutic choices. In this study we evaluated the accuracy and the potential clinical impact of BioFire® FilmArray® Pneumo Plus (FAP) compared to the standard of care (SoC).

Materials/methods: From December 2018 to February 2019, in all consecutive adult ICU patients with suspected VAP, an endotracheal aspirate was collected and sent to the laboratory for rapid microbiologic testing with FAP. The results were compared with the SoC, represented by quantitative cultures. For viral target detections, the decision whether to confirm the result with a different molecular assay was left to the judgement clinicians. The potential clinical impact of FAP was evaluated registering the changes to the empiric antibiotic therapy that could have been possible based on its results.

Results: Fifty-seven samples from 37 patients were analysed. One test (1.8%) resulted invalid. A full concordance between the two methods was observed in 25/57 (43.9%) samples. FAP detected an additional bacterial target in 31/57 samples (54.4%) and a genetic marker for methicillin resistance in 2/10 samples positive for S. aureus, resulted methicillin susceptible by SoC. There were not cases of bacterial targets missed by FAP. Fourteen viral targets were detected from 13/57 (22.8%) specimens, with Influenza virus A being the most frequent. In one case, the detection of a viral target by FAP was not confirmed by SoC. Antibiotic adjustments to the empiric therapy could have been possible in 31/56 cases (55.4%); escalation in 13/56 cases (23.2%) and de-escalation in 17/56 (30.4%). In 5 cases (8.9%), escalation would have included an antiviral agent.

Conclusions: FAP allows for a rapid and reliable detection of common pathogens for VAP in lower respiratory tract specimens. The use of FAP in patients with suspected VAP could shorten the time to a targeted and effective antibiotic treatment, reducing the inappropriate or unnecessary use of antibiotics.

Absence of the Type I-E CRISPR-Cas system in *Klebsiella pneumoniae* clonal complex 258 is associated with dissemination of *bla*<sub>KPC</sub> plasmid in this clonal complex

Zhou Ying*1, Tang Yu2, Xiaofei Jiang1

1Department of Laboratory Medicine, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China 2Department of Laboratory Medicine, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China

**Background:** *Klebsiella pneumoniae* carbapenemase (*KPC*)-producing *K. pneumoniae* (*KPC-KP*) have disseminated worldwide and emerged as major threats to public health. Of epidemiological significance, the international pandemic of *KPC-KP* is primarily associated with CG258 isolates and the related *bla*<sub>KPC</sub>-IncF plasmids. The CRISPR-Cas system is an adaptive immune system that can hinder gene expansion driven by horizontal gene transfer (HGT), including the spread of antibiotic resistance. Because *bla*<sub>KPC</sub>-IncF plasmids are favored by CG258 *K. pneumoniae*, it was of interest to examine the co-distribution of CRISPR and acquired *bla*<sub>KPC</sub>-IncF plasmids in CC258 *K. pneumoniae* lineages.

**Materials/methods:** The prevalence of CRISPR-Cas and *sdhCDAB* operon were investigated among 203 whole-genome sequences in GenBank and 459 clinical isolates of *K. pneumoniae*. The real-time PCR was performed to measure the expression of relative genes and the promoter activity was determined by β-galactosidase assay. The conjugation assay, plasmid stability experiments and plasmid-loss examine were applied to evaluate the function of CRISPR-Cas system in *K. pneumoniae*.

**Results:** We observed that the type I-E CRISPR-Cas system was significantly scarce in the CG258 lineage (*p* < 0.0001) and the associated host-factor (*sdhCDAB*) in these isolates differed from other *K. pneumoniae*. We demonstrated that the CRISPR-Cas system in *K. pneumoniae* could effectively hindered *bla*<sub>KPC</sub>-plasmid invasion and existence and most IncF *bla*<sub>KPC</sub>-plasmids in this study were proved to be good targets of CRISPR. Furthermore, for the first time, *sdh* was experimentally shown to be a CRISPR activator. Intriguingly, the *sdh* mutations in CG258 *K. pneumoniae* also affected the CRISPR activity, the function of mutant *sdh* is weaker. This regulatory mutation impacted the CRISPR inhibition of *bla*<sub>KPC</sub>-plasmid propagation in *K. pneumoniae*.

**Conclusions:** Overall, our work suggests that the CRISPR-Cas system, coupled with a robust activator, may play a role in antagonizing the occurrence of *bla*<sub>KPC</sub>-IncF plasmids in strains not belonging to CG258, providing a new perspective on the tricky connection between *K. pneumoniae* CG258 and *bla*<sub>KPC</sub> dissemination.

Abstract 4673

**Antimicrobial screening of 2208 UK isolates (2003-2018) using novel Legionella Medium (LASARUS)**

Edward Anthony Reginald Portal*1, Kirsty Sands1, Baharak Afshari2, Victoria Chalker2, Brad Spiller1

1Cardiff, Division of Infection and Immunity, Cardiff, United Kingdom, 2Public Health England, London, United Kingdom

**Background:** Epidemiological Cut-Off Values (ECOFF) are not available for Antimicrobial breakpoint thresholds for Legionella. This is due to variance in Antimicrobial Sensitivity Testing (AST) results from Broth MicroDilution (BMD) and BCYE solid media. The presence of activated charcoal in BCYE media removes growth inhibitors but also chelates Antimicrobials affecting results. LASARUS (Legionella Antimicrobial Susceptibility And Resistance Universal Screening), a new charcoal-free solid medium, was validated against BMD and BCYE for Legionella AST determination. The first line therapeutic for Legionella spp. is azithromycin. The presence/absence and mutations in commonly associated genes with decreased susceptibility to Antimicrobials were investigated.

**Materials/methods:** Initial MICs for a reference panel of 10 L. pneumophila strains and 45 representative clinical isolates were determined in quadruplicate on BCYE traditional agar, LASARUS agar and compared to published gold-standard BMD methods. AST for 2208 clinical and environmental Legionella isolates (2003-2018) were performed using an automated multipoint inoculator on LASARUS agar on a 2-fold series of antimicrobial dilutions (Table 1). MIC confidence intervals and distribution were analysed by GraphPad Prism; isolates with higher MIC values were identified. Preliminary Whole Genome Sequencing (WGS) (Illumina, MiSeq) was carried out on 40 strains with elevated azithromycin MICs to determine underlying mechanisms. Fastq files were assembled by SPAdes v3.9.0 and analysed by srst2 using ARGannot resistance gene database and Geneious prime to identify resistance-mediating somatic mutations.

**Results:** LASARUS showed complete concordance for MIC50 and MIC90 values to BMD. BCYE MIC values were higher (up to 32-fold). MIC50 and MIC90 are given in Table 1 for the complete 2208 isolate archive. Between 1-11% of isolates for each antimicrobial showed elevated MICs. WGS analysis of 40 of the elevated azithromycin MIC isolates identified the lpeAB gene, for first time identified in the UK. No 23S rRNA, L4 or L22 mutations were identified and the presence of ermA, ermB, ermC, ermF, mphA, ereA or ereB genes were not found.

**Conclusions:** LASARUS gave concordant results to BMD, unlike BCYE, and is suitable for high-throughput automated AST determination. The gene lpeAB is present in UK isolates of L. pneumophila with elevated MIC to azithromycin.

Abstract 4674

**Mortality in patients with Staphylococcus aureus bacteraemia and the implications of Staphylococcus aureus bacteriuria for in-hospital: results of a monocentric retrospective cohort study**

Tobias Kramer*1,2, Beate Schlosser1,2, Frank Schwab1,2, Desiree Gruhl1, Michael Behnke1,2, Petra Gastmeier1,2, Rasmus Leistner1,2

1Charité Universitätsmedizin Berlin, Institute for Hygiene and environmental medicine, Berlin, Germany, 2Charité Universitätsmedizin Berlin, National Reference Center for Surveillance of Nosocomial Infection, Berlin, Germany

**Background:** Staphylococcus aureus bloodstream infection (SA-BSI) is an infection with elevated risk for morbidity and mortality. Concomitant Staphylococcus aureus bacteriuria (SABU) frequently occurs in patients with SA-BSI. The clinical implications are still under investigation. In this study, we investigated the role of SABU in patients with SA-BSI and its effect on the patients mortality.

**Materials/methods:** We performed a retrospective cohort study that included all patients at the three hospital of our university medical center (Charité Universitätsmedizin Berlin) between January 1, 2014 and March 31, 2017. We included all patients with positive blood cultures for *Staphylococcus aureus* who had a urine culture taken 48 hours before or after sampling of the first positive blood culture. We identified cases using the microbiology database and collected additional demographic and clinical parameters retrospectively from patient files and charts. We conducted univariate analyses and multivariable logistic and Cox regression analyses to evaluate risk factors for in-hospital mortality.

**Results:** Of 1139 Patients with SAB 202 patients met the eligibility criteria. Overall, 55 patients (27.5%) died during their hospital stay. Multivariable analyses showed that SABU (OR 2.2; 95%CI:1.04-4.54) and a Pitt Bacteremia Score of >1 [OR 6.11; 95%CI:2.91-12.81] as well as moderate to severe liver disease [OR 2.96; 95%CI: 1.09-8.04] were independent risk factors for in-hospital mortality.

**Conclusions:** Our data indicates that SABU in patients with concurrent SA-BSI is a prognostic marker for in-hospital death. Further studies are needed to evaluate implications for therapeutic optimization.

Cox proportional hazards regression of patients with SA-BSI.

Abstract 4678

Clinical and bacteriological outcome in urinary tract infections caused by ESBL-producing Enterobacterales and characterisation of isolated pathogens: a prospective, multi-centre study

Hanna Montelin1, Angela Camporeale2, Anna Hallgren1, Malin Vading3,4, Christian Giske2,4, Thomas Tängdén1

1Uppsala University, Department of Medical Sciences, Uppsala, Sweden, 2Karolinska Institutet, Department of Laboratory Medicine, Division of Clinical Microbiology, Stockholm, Sweden, 3Danderyds hospital, Department of Infectious Diseases, Stockholm, Sweden, 4Karolinska University Hospital, Department of Clinical Microbiology, Stockholm, Sweden

Background: Oral treatment options are scarce for urinary tract infections (UTIs) caused by ESBL-producing *E.coli* and *Klebsiella spp.* and there is limited evidence to support therapeutic decisions. This study aimed to assess current treatment strategies for these infections, clinical and bacteriological outcomes, and phenotypic and genotypic characteristics of the causative bacteria.

Materials/methods: A prospective, multicentre, observational cohort study was conducted at 15 sites in Sweden during 2014-2017. Patients diagnosed with UTI and significant growth of ESBL-producing bacteria in urine were included. Clinical and bacteriological cure after 10–14 days and relapse within three months upon completion of therapy was assessed. When possible, the isolated bacteria were collected and subjected to MIC determination and genotypic characterisation using whole-genome sequencing.

Results: 236 cases (108 febrile UTI, 128 lower UTI) caused by *E. coli* (*n*=221) and *Klebsiella spp.* (*n*=15) were included. The median duration of therapy for febrile UTI was 10 days. Clinical and bacteriological cure rates were 84% and 81%, respectively. Intravenous treatment was administered ≥4 days in 57% of the cases, while 32% of the patients were prescribed only oral antibiotics. Pivmecillinam was prescribed as oral follow-up [median duration 6 days] in 20 cases following intravenous treatment [median duration 4 days]; no treatment failure was observed in this group. For lower UTI, the median duration of treatment was 5 days. Clinical and bacteriological cure rates were 81% and 85%, respectively. Clinical cure was achieved in 80% (*n*=49) of patients treated with pivmecillinam alone and in 79% (*n*=53) of patients treated with nitrofurantoin alone. Clinical success was lower in complicated and recurrent UTI. Relapse occurred in 15% of the patients. Aminoglycoside resistance genes were detected in 146 of 169 tested isolates. All but two *E.coli* strains had at least one adhesin gene; among them, ST131 was the most common. ST131 was associated with treatment failure and relapse, while ST69 was associated with clinical cure.

Conclusions: Clinical and bacteriological cure rates were generally high in this cohort despite that non-evidence-based treatment was frequently used. Co-morbidities, recurrent infection and ST131 were associated with a higher risk of treatment failure.

Characterisation of biofilm formation by *Staphylococcus pseudintermedius* on a variety of medical devices

Camilla Pesset¹, Milena Antunes², Carolina Fonseca³, Marcella Ferreira³, Izabel Teixeira², Eliane De Oliveira Ferreira¹, Bruno Penna*²

¹Universidade Federal Fluminense - Campus Valonguinho, Universidade Federal Fluminense, Laboratório de Cocos Gram Positivos, Niteroi, Brazil, ²Universidade Federal Fluminense - Campus Valonguinho, Universidade Federal Fluminense, Laboratório de Cocos Gram Positivos, Niteroi, Brazil, ³Instituto de Microbiologia Paulo de Góes, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract third-party references: CNPq, FAPERJ, Bill & Melinda Gates Foundation, CAPES

**Background:** Health care-associated infections (HCAIs) are associated with biofilm-forming bacteria and represent a concerning problem difficult to eradicate. The genus *Staphylococcus* is responsible for majority of HCAIs cases not only in humans but in veterinary medicine as well. The capacity of biofilm formation is the main reason of persistent surgical site infection and is associated with implants in dogs, caused by *Staphylococcus pseudintermedius*, including methicillin susceptible and resistant strains (MSSP and MRSP respectively). MRSP can also be considered a public health problem, since zoonotic transmission can occur. The aim of the study was to evaluate the capacity of biofilm formation by *Staphylococcus pseudintermedius* in titanium orthopaedic material and different suture materials commonly used in small animal surgery, as well as genetically evaluate the biofilm formation.

**Materials/methods:** Sterile titanium nuts and four types of sutures were tested. Suture threads were aseptically cut into 1cm segments. Sterile titanium nuts and suture segments were incubated in tryptone soy broth supplemented with 1% glucose of standard suspensions of eight *S. pseudintermedius* isolates, in 24 well plate overnight. The biofilm production was measured by optical density (OD) after vortexing of each suture segment and titanium nuts. Then were stained with safranin, in triplicate. Bacterial adherence to suture and titanium nuts were assessed by use of scanning electron microscopy. The genes associated with biofilm formation (*icaA* and *icaD*) were identified by PCR.

**Results:** In nylon suture, all isolates were classified as non biofilm producers, but in polyglycilic acid, all isolates were able to form biofilm. In cotton, 75% (6/8) were biofilm producers and 12,5% (1/8) were biofilm producers in polypropylene. Seven isolates (87,5%) were able to form biofilm in titanium nut and only one isolate (12,5%) was classified as non biofilm producer. PCR revealed the presence of the two genes (*icaA* and *icaD*) in all the isolates.

**Conclusions:** Was observed the biofilm formation in orthopaedic material composed of titanium. Biofilm formation was observed in several types of suture, especially cotton and polyglycolic acid. There was no biofilm formation in nylon suture. All the samples evidenced the presence of the *icaA* and *icaD* genes.

Patients presenting with malaria: are we missing opportunities to screen for other travel-associated infectious diseases?

Emma Mcguire*, John Klein¹, Anna L. Goodman¹

¹Guys & St Thomas Nhs Foundation Trust, London, United Kingdom

**Background:** British Infection Association malaria guidelines do not incorporate guidance on any tropical or travel screening. 85% of UK cases are acquired through travel to Africa, predominantly among people of African origin visiting friends and relatives¹. Screening of newly arrived migrants for HIV, hepatitis B, hepatitis C, strongyloides and schistosomiasis is recommended as it is likely to be cost-effective². We sought to determine if it is similarly cost-effective to screen patients who present with malaria.

**Materials/methods:** All cases of malaria diagnosed between January 2017 and December 2018 were identified from our in-patient electronic system. Electronic patient records were interrogated for serological results for HIV, hepatitis B, hepatitis C, strongyloides, schistosomiasis and filariasis. For cases with positive serological tests, notes were reviewed to determine treatment and follow-up.

**Results:** Over the 2-year period 131 patients were diagnosed with malaria through our emergency department. Malaria was acquired in Africa 127 (97%), mainly West Africa (90%). 111 (85%) patients underwent HIV screening; 4 (4%) positive – all were known to have HIV, and 2 (2%) indeterminate results. 98 (75%) underwent hepatitis B surface antigen screening; 7/98 (7%) positive, 5 were known and 2 were new but lost to follow-up. 44 (34%) were tested for hepatitis C IgG; all were negative. 37 (28%) had strongyloides serological screening; 3/37 (8%) positive and treated and 2/37 (5%) borderline reactive serology which were negative on repeat testing. 27 (21%) were tested for schistosoma antibodies; 4/27 (15%) positive of whom 2 were treated and 2 did not attend follow-up, and 2/27 (7%) borderline positive serology which were negative on repeat testing. 3 (2%) had filaria antibody screening; all negative. Of 14 cases aged <16 years, 2 (14%) were screened for BBV, and 1 (7%) for strongyloides and schistosomiasis.

**Discussion:** The rates of HIV, hepatitis B and hepatitis C in our local population are 0.012%, 0.5% and 1.2% respectively³. Our findings suggest seroprevalence to be 250 times and 14 times higher for HIV and hepatitis B respectively as well as significant rates of strongyloides and schistosoma seropositivity, suggesting presentation with malaria is an opportunity to cost-effectively screen for these treatable infections.

Population-based incidence and mortality of community-acquired pneumonia in Germany

Ralf Sprenger1, Friedhelm Leverkus2, Jochen Walker3, Dennis Haeckl4, Christof Von Eiff5*, Christian Theilacker1, Julia Schiffner-Rohe6

1Pfizer Pharma GmbH, Berlin, Germany, 2Pfizer Deutschland GmbH, Berlin, Germany, 3Institut für angewandte Gesundheitsforschung Berlin GmbH, Berlin, Germany, 4Scientific Institute for Health Economics and Health System Research GmbH, Leipzig, Germany

Abstract 4684

Background: Representative data on the burden of community acquired pneumonia (CAP) in adult pneumococcal vaccine eligible populations in Germany are currently scarce.

Materials/methods: Rates of CAP population-based incidence and mortality were estimated in a retrospective cohort study using a representative healthcare claims database of approx. 4 million insured persons in 2015. Incidence according to the base case was estimated by a CAP ICD-10 code in the first coding position or a CAP ICD code in the second position in combination with a sepsis diagnosis in the first position. Outpatient CAP was defined as a CAP ICD code plus an antibiotic prescription within 7 days after incident diagnosis. Chronic underlying illness predisposing to pneumococcal disease (at-risk conditions) were defined according to STIKO.

Results: Incidence rates of CAP are described in the table. In adults ≥60 years, the incidence of hospitalized CAP was underestimated by the base case compared to the diagnosis of CAP in the primary or secondary positions (Sensitivity analysis 1; IR: 1061 vs. 1560). In contrast, incidence of outpatient CAP that required a chest x-ray confirmation underestimated CAP incidence compared to the base case (Sensitivity analysis 2; IR: 1053 vs. 413). The 30-day and 1-year CAP mortality rates was 24.5% and 47.4% in adults aged ≥60 years and 8.6% and 15.0% in at-risk adults aged 16 to 59 years.

Conclusions: The burden of CAP among adults eligible for pneumococcal vaccination in Germany remains high and mortality rates in our analysis exceeded those previously reported. Using sensitive case definitions is key to obtain full estimates of the CAP burden. Effective pneumococcal vaccination strategies for the prevention of CAP and its associated mortality is needed.

Table. Incidence rates (IR) of community-acquired pneumonia in Germany per 100,000 PYO in 2015

Quantiferon-TB Gold Plus: comparison of interferon-γ detection by ELISA and CLIA assay

Giulia Lombardi1, Francesco Bisognin1, Silvia Felici1, Paola Monari1, Eleonora Gatti1, Maria Carla Re1, Paola Dal Monte*1

1S. Orsola-Malpighi University Hospital, Microbiology Unit - Department of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy

Background: Latent tuberculosis infection (LTBI) is defined as a state of persistent immune response to Mycobacterium tuberculosis complex (MTBc) without clinically manifested evidence of active TB disease. About 1.7 billion people worldwide are estimated to have LTBI, and are thus at risk of developing active TB disease during their lifetime. Two tests are available for the identification of LTBI: the tuberculin skin test (TST) and the interferon gamma (IFN-γ) release assays (IGRAs). They represent indirect markers of MTBc exposure and indicate a cellular immune response to MTBc. Among IGRAs, Quantiferon-TB Gold Plus (QFT-Plus, Qiagen) measures IFN-γ released by T-cell (both CD4+ and CD8+) following stimulation by MTBc-specific antigens. Aim of this study was to compare the results of QFT-Plus obtained by ELISA with those obtained with chemiluminescence immunoassay (CLIA) on the LIAISON XL analyser.

Materials/methods: In this comparative study, 197 Quantiferon-TB Gold Plus blood samples were processed in parallel for IFN-γ detection with the routinely ELISA method (on the SKYLAB automated system, DASIT) and with CLIA system on the LIAISON XL (DiaSorin). For each patient, IFN-γ results from the 4 tubes (Nil, TB1, TB2 and Mitogen) were combined in a single qualitative (positive, negative and indeterminate) result according to manufacturer’s instruction; IFN-γ quantitative values of each tube were also recorded.

Results: Among 197 samples processed with ELISA, 20 were not tested by LIAISON due to insufficient blood volume in one or more tubes. On the remaining 177 samples, the overall agreement between ELISA and CLIA assays was 89.8% (κ=0.822). Among discordant results, 2 ELISA positive samples became Indeterminate with CLIA for high level of IFN-γ in the Nil tube; 3 negative ELISA samples (in the grey zone) became positive with CLIA; and 12 of 25 indeterminate ELISA samples for a low IFN-γ level in the Mitogen, became determinate, with a negative result, with CLIA.

Conclusions: IFN-γ detection by chemiluminescence assay on the LIAISON XL analyser is more sensitive than ELISA. Within the linearity range of the test, the LIAISON system detects higher quantitative values than ELISA assay.

Abstract 4686

**Maraviroc in PML-IRIS associated with immunotherapies: a case series**

Raphaël Bernard-Valnet*1, Xavier Moisset2, Nicolas Maubeuge3, Jean Christophe Ouallet4, Mathilde Roumier5, Christine Lebrun Frenay6, Pierre Labauge1, Pierre Clavelou1, Jean Philippe Neau2, Renaud Du Pasquier1, Roland Liblau8, David Brassat8, Guillaume Martin-Blondel8

1Centre Hospitalier Universitaire Vaudois, Clinical Neurosciences department, Lausanne, Switzerland, 2CHU Clermont-Ferrand, Department of Neurology, Clermont-Ferrand, France, 3CHU de Poitiers, Department of Neurology, Hôpital La Milétrie, Poitiers, France, 4CHU de Bordeaux, Service de neurologie, pôle des neurosciences cliniques, Bordeaux, France, 5CHU Henri Mondor, Service de Médecine Interne, Créteil, France, 6CHU de Nice, Université Nice Côte d’Azur, CRCSEP Nice, Neurologie Pasteur Z, Nice, France, 7CHU de Montpellier, MS Unit, Montpellier, France, 8CHU de Toulouse, Infectious disease, Immunology and Neurology departments, Toulouse, France

**Background:** Rise of the use of immunosuppressing therapies for treatment of chronic inflammatory diseases have been associated with an increase of progressive multifocal encephalopathy (PML) cases. Treatment of PML consist in restoration of antiviral immunity that may be complicated by an immune reconstitution syndrome (IRIS). IRIS is caused by massive entry of CD8 T cells (mainly bearing the CCR5 chemokines receptor) that would clear JC virus but also lead to a disproportionate tissue damage. Maraviroc, a CCR5 antagonist, have been proposed to prevent or treat IRIS. In this work, we aimed to assess maraviroc efficacy in PML-IRIS associated to immunotherapies.

**Materials/methods:** We retrospectively collected clinical and radiological data of cases from 8 university hospital in France and one in Switzerland. We performed a meta-analysis of cases reported in the literature. Primary endpoint was clinical aggravation after maraviroc introduction.

**Results:** We identified 19 cases in France/ Switzerland and 6 from the literature. Among them 16 met inclusion criteria [12 cases from our cohort and 4 from the literature]. All patients develop PML in relation with immunosuppressive treatment for chronic inflammatory diseases [15 multiple sclerosis, 1 rheumatoid arthritis]. Mean age at onset was 43.2 [33-61]. PML presented clinically in half of cases and have been detected on control MRI in the other half. Onset was progressive in most cases (62,5%) and not associated with radiological hallmarks of inflammation (eg, Gadolinium enhancing lesions, 69%). In 50% of patients Maraviroc was introduced to prevent IRIS/ Inflammatory PML and for the rest of them to treat it. In most of them Maraviroc was given in association with corticosteroids. However, despite maraviroc 7/16 (44%) patients met primary endpoint of neurological worsening. There was no differences between prevention and treatment group. Only 2 patients (12.5%) died, one from PML progression and the other one from hematological neoplasia.

**Conclusions:** Overall, this study provide non strong evidences to support the use of maraviroc in PML-IRIS.

**Presenter email address:** raphael.bernard-valnet@chuv.ch
Respiratory pathogens detected in children with community-acquired sepsis-like syndrome in 6 European countries

Veerle Matheeussen*1,2, Katherine Loens1,2, Kevin Jacobs2, Peter Horby1, Herman Goossens1,2, Malte Kohns Vasconcelos4, Mike Sharland4, Menno De Jong5, Marion P. G. Koopmans6, Pieter Fraaij6, Margareta Ieven2

1University Hospital Antwerp, Edegem, Belgium, 2University of Antwerp, Antwerpen, Belgium, 3University of Oxford, London, United Kingdom, 4St George’s, University of London, London, United Kingdom, 5University of Amsterdam, Amsterdam, Netherlands, 6Erasmus University Rotterdam, Rotterdam, Netherlands

Abstract third-party references: PREPARE Project Group, funded by the European Commission under FP7

Background: The management of infants admitted to hospital with sepsis-like syndrome (SLS) without apparent focus remains challenging. There is growing evidence indicating that this clinical picture is triggered by viral pathogens, like adenovirus, enterovirus or parechovirus with a possible respiratory point of entry. We aimed to identify an association in the presence of respiratory pathogens in nasopharyngeal swabs between children with SLS and controls.

Materials/methods: A total of 102 children (≤ 6 months old) admitted to hospital with community-acquired SLS and 308 asymptomatic controls (0-6 years old) were enrolled in a prospective case-control study as part of the MERMAIDS Trial (Multi-centre EuRopean study of MAjor Infectious Disease Syndromes, www.prepare-europe.eu) in 12 hospitals in 6 European countries. The Fast Track Diagnostics Respiratory pathogens 21 plus real-time PCR assay was used to determine the presence of respiratory pathogens in nasopharyngeal swabs.

Results: The most prevalent respiratory viral targets detected in the nasopharyngeal swabs of SLS patients were rhinovirus (28%), RSV A/B (9%), enterovirus (8%) and parainfluenzavirus (5%). All other viruses (influenzavirus, coronavirus, parechovirus, human metapneumovirus, adenovirus and bocavirus) were detected in <5%. Also bacterial targets like Staphylococcus aureus and Streptococcus pneumoniae, possibly colonizers, were often detected, both in 30% of the samples. Neither Mycoplasma pneumoniae, Chlamydophila pneumoniae nor Haemophilus influenzae type B were present. Compared to the control group, enterovirus and RSV A/B were detected more frequently in the SLS patients (8 versus 2% for enterovirus, p=0.01 and 9 versus 2% for RSV A/B, p=0.01). Adeno- and bocavirus were found more often in the control group (7 versus 1% for both viruses, p=0.02). No respiratory target was detected in 25% of the SLS samples.

Conclusions: Most (75%) of the nasopharyngeal samples from SLS patients contained one or more viral or bacterial respiratory targets. In our study, the role of influenza viruses was relatively limited. The possible role of enterovirus and RSV A/B in the pathophysiology of SLS should be further elucidated.

Abstract 4692

Gene expression pattern analysis using dual-color RT-MLPA and integrative genome-wide association studies of expression quantitative trait loci (eQTL) for tuberculosis susceptibility

Jingwen Ai*, Hanyue Zhang1, Wenhong Zhang1

1Huashan Hospital, Fudan University, Shanghai, China

Abstract third-party references: On behalf of Jing-wen Ai

Background: When infected with Mycobacterium tuberculosis, only a small proportion of the population will develop active tuberculosis, and the role of host genetic factors in different tuberculosis infection status were still not fully understood.

Materials/methods: Forty-three active tuberculosis patients and 49 latent tuberculosis infection individuals were enrolled in the prospective cohort. Expressing levels of 27 candidate mRNAs, which were previously demonstrated to differentially transcript between latent and active tuberculosis, were measured by dual color reverse transcription multiplex ligation dependent probe amplification assay (dcRT-MLPA). Using expression levels of these mRNAs as quantitative traits, associations between expression abundance and genome-wide single nucleotide polymorphisms (SNPs) were calculated. Finally, identified candidate SNPs were further assessed of their association with tuberculosis infection status in the validation cohort of 313 Chinese Han population.

Results: We identified 9 significantly differentially expressed mRNAs including il7r, il4, il8, tnfrsf1b, pgm5, ccl19, il2ra, marco and fpr1 in the prospective cohort. Through expression quantitative trait loci mapping, we screened out 8 SNPs associated with these mRNAs and CG genotype of the SNP rs62292160 was finally verified to be significantly associated with transcription levels of il4 in tuberculosis patients (Figure 1).

Conclusions: We reported that the SNP rs62292160 in Chinese Han population may link to the regulation expression of il4 in tuberculosis. Our findings provided new genetic variation loci for further exploration of the mechanism of tuberculosis and a possible target of tuberculosis genetic susceptibility studies, which might aid the clinical decision to precision treatment of tuberculosis.

Figure 1 (A). Manhattan plot. The expression levels of mRNAs were associated with single nucleotide polymorphisms. The p value of green plots was less than E\(^{-05}\). Figure 1 (B). Regulatory network of mRNAs and SNPs related genes. The genes were surrounded by a red rectangle and the RNAs were surrounded by a blue rectangle. Seven genes and 9 mRNAs were in this network. Figure 1 (C). We validated the identified 8 SNPs and the histogram was performed to show the variations of selected SNPs in active tuberculosis (ATB) and latent tuberculosis infection (LTBI) patients. The rs62292160 had significant differences in ATB and LTBI patients.

The urinary pharmacokinetics of nitrofurantoin in patients with uncomplicated urinary tract infections: interim analysis

Rixt Anna Wijma1, Birgit Koch1, Teun Van Gelder1, Eva Van Haren2, Huda Karim2, Sander Croes3,4, Anouk Edwina Muller*1,5
1Erasmus University Medical Center, Rotterdam, Netherlands, 2University of Utrecht, Utrecht, Netherlands, 3Maastricht University Medical Center, Maastricht, Netherlands, 4CAPHRI-Care and Primary Health Research Institute, Maastricht University Medical Center, Maastricht, Netherlands, 5Haaglanden Medical Center, The Hague, Netherlands

Background: Nitrofurantoin was registered for uncomplicated urinary tract infections (UTI) in 1954. At that time, a structured process of drug development was not yet mandatory. As a consequence, nitrofurantoin is being prescribed based on very limited data supporting the currently used dosing regimen. A better knowledge of the pharmacokinetic (PK) properties would help to achieve optimal dosing regimens. Our aim was to investigate and compare the urinary PK profile of nitrofurantoin in two commonly used dosing regimens in patients with uncomplicated UTI.

Materials/methods: Urine samples were collected during 24 hours in 13 females who were prescribed nitrofurantoin 50 mg q6h (Macrodantin®/Furadantin®), and in 7 patients who were prescribed 100 mg q12h (Macrobid®/Furabid®) by their treating general practitioner for the treatment of an uncomplicated UTI. Nitrofurantoin concentrations in urine were quantified by UHPLC-UV. PK analysis was performed by PKSolver® using non-compartmental analysis.

Results: Mean peak concentrations of nitrofurantoin in urine after 100 mg were higher compared to those after 50 mg (104.2 mg/L ± 74.7 versus 84.7 mg/L ± 64.6), but the range in maximum concentrations was comparable (0.7 mg/L to 257.7 mg/L). The AUC0-24h,ss was higher (931.5 mg.h/L ± 672.3 versus 881.9 mg.h/L ± 347.1) after the 100 mg dosing regimen. The slow-release effect of the 100 mg capsule, demonstrated as a delayed peak concentration, was observed but none of the PK parameters differed significantly between the dosing regimens. Urinary concentrations exceeded the EUCAST ECOFF of nitrofurantoin for Escherichia coli of 64 mg/L in only 10 out of 119 samples in the 50 mg group and in 9 out of 78 samples in the 100 mg group. In 8 patients (n=6 in the 50 mg group), concentrations never exceeded the ECOFF.

Conclusions: The urinary PK of nitrofurantoin was comparable between the two studied dosing regimens and therefore independent of the administered dose and formulation. The amount of nitrofurantoin administered might be too low, as urinary concentrations did not exceed the ECOFF for Escherichia coli in the majority of the samples. Additional PK studies as well as determination of the PK/PD target on Macrobid®/Furabid®, are needed.

Abstract 4696

The transmission risk of multidrug-resistant organisms between pets and humans: an exploratory case control study protocol

Carolin Hackmann*1, Petra Gastmeier1, Desiree Gruhl1, Betty Laos De Henner1, Antina Lübke-Becker2, Stefan Schwarz2, Rasmus Leistner1

1Charité - Universitätsmedizin Berlin, Institut für Hygiene und Umweltmedizin, Berlin, Germany, 2Freie Universität Berlin, Department of Veterinary Medicine, Berlin, Germany

Background: This project aims to assess the relevance of pet husbandry in the colonization of multidrug-resistant organisms (MDROs) of hospital patients. Currently, the potential role of pets as reservoirs of MDROs is still unclear. The project focuses on the most common MDROs in pet owners, methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), 3rd generation cephalosporin-resistant Enterobacterales (3GCRE) and carbapenem-resistant Enterobacterales (CRE).

Materials/methods: To assess the contact to household pets as a risk factor for the colonization with one of the above named pathogens, we perform an exploratory, unmatched case-control-study. Among questions about well-known risk factors, study participants are queried regarding their contact to dogs and cats. This includes information about the number of pets in the household, the closeness of contact and diseases as well as medical treatment of the pets. To assess the genetic relatedness of the human and pet MDROs, we collect nasal and rectal swabs of the participants in the hospital and their pets to test them for MDROs. Phenotypically matching MDROs in the samples of participants and their pets will be tested for genetic relatedness using whole genome sequencing (WGS). The study is currently being performed at the Charité Universitätsmedizin Berlin. The sample size will comprise 4,000-6,000 human participants and aims at 1,000-1,500 animal samples. The study is funded by the Federal Department of Health (BMG).

Results: Among the first 958 participants, 39% (372/958) tested positive for MDROs. 54% (518/958) of participants were male and the mean age was 62 years (18-91 years). 13% of the participants (103/958) stated to own a dog, 9% (89/958) to own a cat. Among the first 112 returned pet samples, 6% (7/112) were positive for MDROs. In two cases MDROs of dog and owner were phenotypically matching. The matching pathogens were in one case VRE and the other case 3GCRE. Further preliminary results of the first 2,000 participants will be presented at the ECCMID 2020.

Conclusions: The investigation of pet husbandry as a risk factor for colonization or infection with MDRO in this study creates an opportunity to identify patients at risk and develop potential prevention strategies.

Carbapenem-resistant *Pseudomonas aeruginosa* in cystic fibrosis children

Ekaterina Samoylova¹, Olga Shamina*², Irina Novikova¹, Tatiana Savinova¹, Anna Lazareva¹

¹National Medical Research Center for Children's Health, Moscow, Russian Federation

**Background:** Bronchopulmonary inflammation in cystic fibrosis children is predominantly associated with carbapenem-resistant (Carba-R) *P. aeruginosa*. It is an important global healthcare problem in pediatrics.

**Materials/methods:** *P. aeruginosa* isolated from lower respiratory tract of patients with cystic fibrosis in 2015-2016 were tested for susceptibility to meropenem and imipenem by the E-test method. Carba-R isolates with a meropenem minimum inhibitory concentration (MIC) >8 and/or imipenem MIC >4 were selected for further analyses. Carbapenemase carriage was detected by Real-time PCR. Sequence type (ST) was determined using multilocus sequence typing (MLST).

**Results:** In total, 75 *P. aeruginosa* isolates were collected; among them 29 (%) isolates were resistant to meropenem and/or imipenem. Only two isolates (7%) harbored *bla*<sub>VIM</sub>. The remaining 27 isolates were negative for *bla*<sub>VIM</sub>, *bla*<sub>IMP</sub>, and *bla*<sub>NDM</sub> carriage. Overall, MLST analysis revealed 20 STs. Five leading STs included ST235 (n=5; 17.2%), ST2595 (n=3; 10.3%), ST527 (n=2; 6.8%), ST798 (n=2; 6.8%), ST2464 (n=2; 6.8%) that collectively comprised 46% proportion of the collection. The remaining STs were represented by ST2758, ST2693, ST1621 (3.4%), ST1129 (3.4%), ST1062 (3.4%), ST882 (3.4%), ST845 (3.4%), ST649 (3.4%), ST612 (3.4%), ST446 (3.4%), ST362 (3.4%), ST252 (3.4%), ST244 (3.4%), ST189 (3.4%), ST9 (3.4%) (n=1 for each ST).

**Conclusions:** Carbapenem resistance in *P. aeruginosa* isolated from lower respiratory tract in cystic fibrosis children in Moscow was not associated with the presence of metallo-beta-lactamases. The *bla*<sub>VIM</sub> gene was detected only in 2 isolates which belonged to ST235. Five lineages including ST235, ST2595, ST527, ST798 and ST2464 dominated among Carba-R *P. aeruginosa* isolates.

The obtained results indicate that further studies are necessary for investigation of the carbapenem resistance mechanisms in *P. aeruginosa* isolated from patients with cystic fibrosis.

Abstract third-party references: On behalf of PROBAC REIPI/GEIH-SEIMC/SAEI Group, Supported by Instituto de Salud Carlos III (PI16/01432)

Background: The objective of this study was to analyze the impact of some genotypic factors of E. coli on mortality in patients with bacteraemia and presentation as sepsis/septic shock.

Materials/methods: A prospective cohort of 143 patients with E. coli bacteraemia and sepsis/septic shock [2016 criteria] from 21 hospitals in Spain, and their blood isolates were analyzed. Whole genome sequencing (Illumina MiSeq Inc) was performed at University Hospital Virgen Macarena. The assembly was done with the CLC Genomic WorkBench (Qiagen) software. Sequence type (ST), virulence factors and antibiotic resistance genes were assessed in MLST 2.0, VirulenceFinder 2.0 and ResFinder 3.2 databases, respectively. A multivariate model only including clinical and epidemiological variables was built by logistic regression; then, individual and grouped microbial genes and STs were added in a stepwise manner. The predictive ability of the models on observed data were measured with the area under the ROC curve with 95% confidence intervals (CI).

Results: Mortality at day 30 was 32.9% (47 patients). Isolates were grouped into 60 clonal groups, ST1 31 (n=21; 14.7%), ST69 (n=17; 11.9%), ST73 (n=14 9 8%) and ST95 (n=9; 6.3%), and 17 (11.8%) isolates were ESBL-producers. The multivariate model for mortality predictors with epidemiological and clinical variables included [OR; 95%CI]: non-urinary source (4.63; 2.06-10.42), Pitt score ≥3 (2.34; 1.05-5.12) and inactive empirical therapy (5.68; 1.37-23.47); the AUROC of this model was 0.74 (95%CI, 0.66-0.82). Microbial factors with a univariate P value <0.2 were added; the best fitted model included the presence of genes that codes for thermostable enterotoxin 1 (astA) (adjusted OR; 95%CI=4.98; 1.10-22.8) and long polar fimbrial protein (lpfA) (4.35; 0.97-19.4) as factors associated with increased risk of death, and the secreted enterotoxin (sehB) [0.19; 0.04-0.77] as protective; the AUROC for this model was 0.83 (95%CI, 0.76-0.91). No better prediction was achieved by including specific sequence types.

Conclusions: These preliminary results suggest that, in patients with bacteraemia and sepsis/septic shock due to E. coli, some specific microbial factors may significantly contribute to mortality. Additional studies are required to characterize the pathophysiological role of this virulence factors in the mortality in patients with sepsis/septic shock due to E. coli.

Presenter email address: natalia.maldonado@yahoo.com
Abstract 4704

Increased fusidic acid resistance among *Staphylococcus aureus* skin and soft tissue infections in Portugal

Teresa Conceição*, Carolina Ferreira¹, Rita Luzio¹, H. De Lencastre²

¹Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Deiras, Portugal, ²Laboratory of Microbiology and Infectious Diseases, The Rockefeller University, New York, United States

**Background:** Fusidic acid (FD) is a first-line antibiotic widely used topically for the treatment of *Staphylococcus aureus* skin and soft tissue (SSTI) and eye infections. Resistance to FD is mainly due to the acquisition of either resistance genes (*fusB, fusC*, and *fusD*) or mutations in the housekeeping *fusA* or *fusE* genes. In Europe, resistance was reported in 10% of infection *S. aureus*, but in Portugal, where FD is commonly prescribed in the community and available over the counter, there is no data regarding prevalence and resistance mechanisms.

**Materials/methods:** To fill this gap, a retrospective collection of infection and carriage *S. aureus* isolated in Portugal were screened for FD resistance: (a) 204 methicillin resistant *S. aureus* representative of the major infection clones in hospitals between 1985 and 2016; (b) 86 *S. aureus* responsible for SSTI in children (n=32) and adults (n=54) in the community and (c) 153 *S. aureus* carriage strains from nasal swabs of homeless individuals (n=44) and nursing students (n=109). FD resistance was confirmed by disc diffusion and microdilution determination of the minimum inhibitory concentration (MIC). Resistance genes were detected by PCR and *fusA* and *fusE* mutations were identified by DNA sequencing.

**Results:** The global prevalence of FD resistance was 7% (31 out of 443 strains). Resistance was more prevalent in SSTI (15.1%, p=0.0033), namely in adults (20.4%, 11 out of 54 strains), and among infection strains (13.4%, p<0.0001). *fusC* was the prevalent determinant, detected in 71% of the resistant strains associated to MICs between 8-16 µg/mL. Five strains showed mutations in the *fusA* gene and a single strain carried *fusB*. Screening of *fusE* mutations is being performed on the remaining three strains that showed none of the previous mechanisms. Half of *fusC* strains (50%) belonged to the Pediatric clone (ST5-IV-t311/t062), whereas *fusB* was associated to the European clone (ST80-IV-t044).

**Conclusions:** In Portugal, resistance to FD in *S. aureus* is mainly related to SSTI in adults (20.4%), highly associated to specific clones and mostly due to the presence of *fusC*. A continuous monitoring of resistance is warranted to ensure the efficacy of FD in the antibiotherapy of SSTI.

**Presenter email address:** teresagc@itqb.unl.pt
Acceptability of a public commitment charter associated with patient information leaflets on antibiotics by general practitioners

Anais Essilini*, Gaelle Le Dref†, Joëlle Kivits†, Adeline Welter‡, Céline Pulcini†, Nathalie Thilly‡,*

†Université de lorraine, APEMAC, Nancy, France, ‡Caisse Primaire d’Assurance Maladie du Bas Rhin, Strasbourg, France, †CHRU Nancy, Infectious Diseases department, Nancy, France, ‡CHRU Nancy, Département Méthodologie, Promotion et Investigation, Nancy, France

Abstract third-party references: ARS Grand Est

Background: Antibio-Charte is a randomised controlled study aiming at evaluating the effectiveness of a toolkit promoting antibiotic stewardship on antibiotics prescribed by general practitioners (GPs) in a French northeast region. This intervention concerned 109 high prescribing French general practitioners (GPs) from October 2017 to September 2018 and included a public commitment charter, a non-prescription pad and a patient information leaflet to be used when antibiotics were prescribed.

Materials/methods: A qualitative study was performed on a sample randomly selected from the 109 GPs included in the intervention group. The semi-directed interview’s guide contained open-ended questions organised around three main themes: their use of each of the three tools, their perception about these tools, and the impact of the intervention on the relationship with patients. Interviews were transcribed and a comprehensive thematic analysis was performed.

Results: A total of 30 GPs were interviewed. The interviews revealed that the intervention was not considered as time-consuming but the GPs’ adherence was sub-optimal. The public commitment charter, displayed in the waiting room, had not created a sense of commitment in GPs as expected. Out of the three provided tools, the non-prescription pad was the most appreciated one although not systematically used. It was perceived as helpful in case of patient pressure to obtain antibiotics. A poster version of the non-prescription pad to be displayed near the consultation bed was often requested. The patient information leaflet to be used when antibiotics were prescribed was perceived as redundant with the prescription and was significantly less used. Some GPs declared being in doubt regarding the effectiveness of the intervention on their antibiotic prescribing while others expected a significant impact.

Conclusions: The perceived usefulness and declared use of the three different documents that were part of the intervention differed significantly. The impact of the intervention on antibiotics prescribed by GPs will be assessed in the near future.

Presenter email address: anais.essilini@univ-lorraine.fr
Background: Methicillin-resistant *Staphylococcus aureus* (MRSA) are among the leading causes of opportunistic infections in human and veterinary medicine worldwide. 33 MRSA isolated from feral and companion animals with *mec* C as the resistance determinant attracted our attention by presenting a broad range of different phenotypes during routine diagnostics. Since *mec* C-MRSA are commonly associated with cattle farms, wastewater, human, wild animals and the environment, we hypothesized that phenotype variation might foster survival of non-epidemic MRSA in these particular niches. To unravel the genomic background and putative accessory gene regulator (*agr*) system variations associated with the divergent phenotypes, we thoroughly investigated the animal *mec* C-MRSA comparatively with 12 closely related isolates of human origin.

Materials/methods: Altogether 45 *mec* C-MRSA were characterized by whole-genome sequence analysis using MLST-1.6, ResFinder-2.1 and VirulenceFinder-1.6 provided by Center for Genomic Epidemiology in Denmark, while Geneious was used to comparatively investigate the isolates’ genomic make-up, including *agr* encoding regions and mobile genetic elements. Phenotype characterization included hemolysis assays, a colony spreading test and biofilm formation capabilities. We also measured protein expression of α-(Hla), β-(Hlb) and δ-hemolysin (Hld) using proteomics.

Results: The 45 isolates were found to belong to clonal complexes (CC) 599, CC49, CC130 and CC1943. While each of the CC investigated was associated with a different accessory gene regulator type (*agr* I-IV), isolates within each lineage displayed different levels of *agr* functionality including completely non-functional variants, resulting in a broad variety of phenotypes. Comparison of the regions encoding *agr* I-IV showed broad range of variation among the isolate collection for each CC, especially among the isolates of animal origin. Functionality of the *agr* system corresponded with differences in protein expression of hemolysins, especially for Hld. Biofilm capabilities differed depending on the assay employed.

Conclusions: Since adaptation is a major driver for genomic changes occurring independently in divergent lineages, our results presumably indicate that *agr* variation may enhance viability and niche adaption capacities of *S. aureus* lineages aside of the epidemic lineages, which are widespread among (wild) animals and the environment, including MRSA. Further research on the impact of phenotypic variation of *mec* C-MRSA is warranted.

Presenter email address: waltherb@rki.de
Impact of diagnostic and antimicrobial stewardship on time-to-appropriate therapy and clinical outcomes in infections caused by carbapenem-resistant Gram-negative organisms

Katie Mccrink1, Kailynn Deronde1, Adriana Jimenez1,2, Gemma Rosello3, Yoichiro Natori3, Kimberly Claes4, Octavio Martinez1,3, Biagio De Pascale1, Armando Perez-Cardona1, Lilian Abbo1,3, Ana Vega1

1Jackson Health System, Miami, United States, 2Florida International University, Miami, United States, 3University of Miami Miller School of Medicine, Miami, United States, 4University of Maryland School of Pharmacy, Baltimore, United States

Background: Carbapenem-resistant Gram-negative organisms (CRGNOs) cause life-threatening infections and incidence is rising globally. Timely effective therapy in these infections has a direct impact on patient survival. We aimed to determine the impact of diagnostic and antimicrobial stewardship (AMS) on time-to-appropriate therapy (TAP) and clinical outcomes of patients with CRGNO infections utilizing novel beta-lactam/beta-lactamase inhibitors (BL/BLIs).

Materials/methods: Retrospective cohort study of adult patients with CRGNO infections at a 1,500-bed University-affiliated hospital in Miami, Florida. Included patients received ≥72 hours of ceftazidime-avibactam (C/A) or ceftolozane-tazobactam (C/T) from 12/2017-10/2019. During the pre-intervention period [12/2017-12/2018], additional susceptibilities (including C/A and C/T) were performed only upon providers’ request. In 01/2019, we implemented reflex algorithms (Figure 1) for faster identification and testing of all CRGNOs including carbapenemase producers. Results were communicated in real-time to the AMS team in order to tailor therapy. Benefit-risk outcomes involving TAP, kidney injury, and mortality were evaluated by desirability of outcome ranking (DOOR) analysis.

Results: Ninety-four patients were included; median age 61 years (IQR 40.0-68.3), 51 (54.3%) were in an intensive care unit at time of culture collection; median APACHE II score was 20 (IQR 15.0 – 27.0). CRGNOs identified included 71 (75.5%) Pseudomonas spp. and 23 (24.5%) Enterobacteriales, of which 16 (17.0%) were carbapenemase producers (KPC=10, NDM=4, VIM=2). The most common infections were pneumonia (47.9%) and bacteremia (26.6%), of which 16 (17.0%) were carbapenemase producers (KPC=10, NDM=4, VIM=2). We found a significant decrease in median TAP (102.9 [IQR 76.0–155.8] vs 75.4 [IQR 56.3–101.2] hours, \( p = 0.003 \)) and length-of-stay (64 [39.9-131.6] vs 43 [20.0-83.8] days; \( p = 0.027 \)) between groups. Median time from culture collection to final susceptibility results was shorter in the post-intervention group (122.2 vs 92.4 hours; \( p < 0.001 \)). In multiple regression analysis, our intervention demonstrated a trend towards decreased 30-day inpatient mortality (OR = 0.36, 95% CI 0.13–1.10). The probability of a better DOOR in the post-intervention group was 73.6% (95% CI 71.3–75).

Conclusions: Our study identified improvement in TAP and clinical outcomes in CRGNO infections with implementation of diagnostic and AMS initiatives. Our intervention had a positive impact on patient survival and initiation of effective therapy with novel BL/BLIs for multidrug-resistant infections.

Antimicrobial activity of ceftobiprole against clinical Staphylococcus aureus isolates from Germany
Franziska Layer*1, Birgit Strommenger1, Ingo Klare1, Guido Werner1
1National Reference Centre for Staphylococci and Enterococci, Robert Koch Institute, Wernigerode, Germany

Background: Ceftobiprole medocaril, the prodrug of ceftobiprole, is a fifth-generation cephalosporin with activity against methicillin-resistant Staphylococcus aureus (MRSA). In most countries it is approved for the treatment of adults with hospital-acquired pneumonia (excluding ventilator-associated pneumonia) and community-acquired pneumonia.

Materials/methods: We performed susceptibility testing of ceftobiprole against (A) 219 clinical S. aureus from the strain collection of the National Reference Centre (NRC), which were isolated before ceftobiprole was introduced for clinical use and (B) 133 contemporary clinical isolates for which the NRC as a reference lab was asked to confirm a putative ceftobiprole resistance phenotype primarily diagnosed in the medical microbiology laboratories. Ceftobiprole MICs were determined by broth microdilution (BMD) and results were interpreted according to EUCAST guidelines. Ceftobiprole Etest (Bestbion) was additionally performed for the contemporary strains. Molecular characterization of isolates included spa-typing, MLST for unknown spa-types and PCR detection of mec genes.

Results: 97.4% of the strains [collection A + B] were susceptible to ceftobiprole with MICs ranging from 0.125 to 4.0 mg/L, exhibiting MIC50/90 values of 1.0/2.0 mg/L. Ceftobiprole resistance [n=9] was exclusively associated with MRSA ST228/ST239, which are at present rare in Germany and were only part of collection A. MRSA of both clonal lineages [n=58] revealed elevated MIC50/90 values of 2.0/4.0 mg/L. We could not confirm ceftobiprole resistance in any of the contemporary isolates sent to the NRC. Comparing MIC determined by Etest with those obtained by BMD revealed that Etest MICs tended to be higher, therefore being closer to the resistance breakpoint, producing false-resistant results and in many cases required a categorization as ATU (area of technical uncertainty) according to recent EUCAST guidelines (v9.0).

Conclusions: Ceftobiprole resistance is rare in S. aureus of prevalent clonal lineages circulating in Germany. Increased ceftobiprole MICs are found in MRSA ST228, disseminated in Southern Europe, and in MRSA ST239, which are described worldwide but are highly prevalent in South East Europe and Asia.

Methods for susceptibility testing of ceftobiprole in clinical microbiological laboratories have to be validated thoroughly, as inconsistent results may lead to overestimation of resistance.

**Rapid diagnostics of Pneumocystis jirovecii: so far not good enough**

Anne-Marthe Urdal Sand*, Andre Ingebretsen1, Jørgen Vildershøj Bjørnholt1

1Oslo University Hospital, Department of Microbiology, Oslo, Norway

**Background:** Pneumocystis jirovecii is an important cause of serious lung infections in immunocompromised patients. Laboratory diagnosis of Pneumocystis jirovecii is based on NAAT (nucleic acid amplification test) and microscopy. Recently rapid and simple commercial tests like eazyplex® Pneumocystis jirovecii have become available on the market, but their performance in the clinical setting is unknown.

**Materials/methods:** We tested 21 bronchoalveolar lavage samples from patients suspected to have a Pneumocystis jirovecii infection. The samples were analyzed with our conventional realtime-PCR [1] and the eazyplex® Pneumocystis jirovecii test [2]. All samples were randomly selected according to the primary results from the PCR (9 negatives /12 positives). Our PCR differentiate CT-values lower than 28 into three groups; weak positive (CT value 28-24, possible colonization), moderate positive (CT value 24-20, possible infection), and strong positive (CT value < 20, probable infection). The eazyplex® Pneumocystis jirovecii kit is based on loop-mediated isothermal amplification (LAMP) and real-time detection of the mitochondrial cox gene. The result is given as positive or negative.

**Results:** All eazyplex® runs were successful. Numbers of concordant and discordant results are presented in table 1.

The eazyplex® Pneumocystis jirovecii test captured only 4 out of totally 12 positive samples (33 %). The other eight positive samples tested negative with eazyplex® Pneumocystis jirovecii despite having CT-values 20 – 27. There were no false positive results with eazyplex® Pneumocystis jirovecii.

**Conclusions:** The eazyplex® Pneumocystis jirovecii captured 33% of the positive samples according to our in-house test, all with strong positive results whereas all of the moderate positive results tested negative with the eazyplex® Pneumocystis jirovecii. Study limitations are low sample size and no pre-analytic concentration of sample specimen. Further validation is warranted.

Antimicrobial activity of enacyloxin IIa and gladiolin against the urogenital pathogens Neisseria gonorrhoeae and Ureaplasma species.

Nicola Heath¹, Richard Rowlands¹, Gordon Webster², Eshwar Mahenthiralingam², Michael Beeton*¹

¹Cardiff Metropolitan University, Cardiff, United Kingdom, ²Cardiff University, Cardiff, United Kingdom

Background: Treatment of urogenital pathogens is becoming increasingly more difficult due to the emergence of multi-drug and extensively-drug resistant strains. Infection with Neisseria gonorrhoeae is increasing on a yearly basis and Ureaplasma spp are intrinsically resistant to many antibiotics.

Materials/methods: The Burkholderia polyketide antibiotics enacyloxin IIa and gladiolin were tested against 14 N. gonorrhoeae and 10 Ureaplasma sp isolates including multi-drug resistant N. gonorrhoeae strains WHO V, WHO X and WHO Z as well as macrolide, tetracycline and ciprofloxacin resistant ureaplasmas. Susceptibility testing of N. gonorrhoeae were carried out by agar dilution, whereas broth micro-dilution and growth kinetic assays was used for Ureaplasma spp.

Results: The MIC range for enacyloxin IIa against N. gonorrhoeae was 0.015 – 0.125 mg/L with MIC50 and MIC90 values of 0.03 and 0.06 mg/L, respectively. The MIC range and MIC50 and MIC90 values for gladiolin were higher at 1 - 2 mg/L, 0.03 and 0.06 mg/L, respectively. The presence of resistance to front line antibiotics had no effect on MIC values. The MIC range for enacyloxin IIa against Ureaplasma spp. was 4 – 32 mg/L with MIC50 and MIC90 values of 8 and 32 mg/L, respectively, with a clear dose-dependent effect when observed using a growth kinetic assay. Gladiolin had no antimicrobial activity on Ureaplasma spp. at 32 mg/L and limited impact on growth kinetics.

Conclusions: Enacyloxin IIa and gladiolin antibiotics have promising antimicrobial activity against a range of antibiotic susceptible and resistant N. gonorrhoeae and Ureaplasma isolates. Development of these compounds warrants further investigation.

Proposition of a uniform methodological approach to attribution of invasive aspergillosis as a cause of death

Rebecca Van Grootveld1, Robert Van De Peppel1, Hendrikje Jolink1, Peter Von Dem Borne1, Alexandra T. Bernards1, Martha Van Der Beek1, Mark G.J. De Boer1

1Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Assessing the cause of death in patients with invasive aspergillosis (IA) is difficult. Presence of underlying disease, cytotoxic treatment as well as the immunocompromised status all may cause severe complications that lead to death. Though criteria for the response to treatment were published by the EORTC, no standard assessment method exists for attribution of mortality in patients diagnosed with IA. In this study a new protocol for the assessment of mortality in IA was constructed and evaluated.

Materials/methods: A scoring model was built based on IA death criteria extracted from the literature (e.g. by Garcia-Vidal et al. 2015). The role IA played in causing the patient’s death was categorised either as attributable, contributable, non-attributable or unknown (figure 1). The scoring model was pre-evaluated by practicing on 12 clinical scenarios. The assessment was performed by a panel of three reviewers consisting of a haematologist, an infectious disease specialist and a clinical microbiologist. Reviewers received written instructions. Each case was independently reviewed by two reviewers, all discrepancies were discussed and final results were based on a consensus among the reviewers. If no consensus was reached, the judgement of the third reviewer was decisive. All adult patients diagnosed with IA who died within 120 days post-diagnosis in the Leiden University Medical Center from 2015-2019 were included.

Results: Fifty-three patients were assessed; each reviewer assessed 36 patients. Mortality was IA-related (attributable or contributable) in 23 (43%) patients, IA-unrelated (non-attributable) in 26 (49%) patients, and unknown in 4 (8%) patients. Judgements were concordant in 29 patients (55%). Most discordant judgements were differences in opinion whether death was non-attributable or contributable (10/24). Progression of underlying haematological malignancy and diagnostic certainty of IA diagnosis (proven and probable versus possible) did not influence the concordance rate of the assessments.

Conclusions: Assessing mortality attributable to IA is complicated and warrants a standardised protocol. The concept of the described methodological approach is promising. Further refinement and validation is necessary so that it can become a standard tool in research involving IA.

Attributable
The immediate cause of death was defined as the disease process, injury, or complication immediately preceding death. IA was considered the cause of death when the immediate cause of death was due to this infection. Examples are neurological complications of a aspergillosis infection that disseminated to the brain, lung bleeding or respiratory insufficiency in a patient with pulmonary aspergillosis.

or
IA was judged to have played a major role if death would not have occurred had the patient not had IA, even though another condition was present that also contributed to death. This includes toxicity, interactions and other side effects of antifungal treatment that played a major role in the cause of death.

Another example is a pseudomonas bacteremia in a patient with a cavitating pulmonary aspergillosis in which the lungs are considered the most likely source of the bacteremia.

Contributable
IA or treatment of IA was defined as playing a minor role if it was probably not essential in explaining the patient’s death but arguably did play some role in the event. Example is a patient with an aspergillus infection as well as severe uncontrolled gastrointestinal GVHD at the time of death.

Non-attributable
Mortality was classified as not related to IA if there was a clear other cause of death.

Unknown
If insufficient data were present about the circumstances in which death occurred.

Figure 1. Attribution of mortality in patients with invasive aspergillosis

1Normandie Univ, UNIROUEN, GRAM EA2656, Laboratoire associé au CNR HIV, CHU de Rouen, Laboratoire de Virologie, Rouen, France; 2Département des agents transmissibles par le sang, Centre national de référence Risques infectieux transfusionnels, Institut National de la Transfusion Sanguine, Paris, France; 3Normandie Univ, UNIROUEN, GRAM EA2656, Laboratoire associé au CNR HIV, CHU de Rouen, Laboratoire de Virologie, ROUEN, France; 4Laboratoire de Virologie, Hôpital Bichat AP-HP Nord, Université de Paris, INSERM U1137, Paris, France; 5Normandie Univ, UNICAEN, GRAM EA2656, CHU de Caen, Laboratoire de Virologie, Caen, France

Abstract third-party references: Supported by Santé Publique France, ANRS and the University Hospital of Rouen

Background: Plasma viral load (VL) is usually used to monitor HIV infected patients. HIV-1 broad genetic diversity frequently affects the performances of commercial assays. Since no reference assay is available regarding HIV-1 VL, most evaluations consist in pairwise comparison. Here we compared HIV-1 VL assays developed on Abbott m2000, Roche Cobas 6800, Hologic Panther and Cepheid GeneXpert platforms, on a wide panel of samples.

Materials/methods: 263 plasma from HIV-1 positive blood donors, 77 viral supernatants (SN), and 300 dilutions of 30 SN [10 replicates of each at 50 cp/ml] representative of HIV-1/M and non-M genetic diversity, and spanning a wide range of VL, were tested for clinical and analytical sensitivity in the 4 usual commercial assays. For each sample, the mean VL obtained with the four assays (Mref) was used as reference to build Bland-Altman graph and compute Passing Bablok regression.

Results: Eight of the 340 plasma and SN were detected but not quantifiable by at least one assay: four concerned minor underquantifications with \( VL_{\text{max}} = 525 \text{cp/ml} \), and four were major underquantifications, with 1 HIV-1/M subtype D misquantified using GeneXpert \( \text{Mref} = 4.52 \text{Log cp/mL} \), and 3 distinct HIV-1/O misquantified using M2000, GeneXpert and Panther \( \text{Mref} = 4.06, 4.86 \) and 5.13 Log cp/mL respectively).

On HIV-1/M samples \( n=300 \), the quantitative analysis showed a very good correlation between the four assays regarding Mref, with means of differences between 0.13 (Cobas) and -0.11Log (M2000), and coefficients of correlation between 0.989 (M2000) and 0.991 (GeneXpert and Panther).

The same analysis on HIV-1/O \( n=32 \) showed means of differences between 0.61 (Cobas) and -0.39Log (M2000) and coefficients of correlation between 0.539 (M2000) and 0.701 (GeneXpert).

Regarding the 230 HIV-1/M dilutions, 100%, 73%, 64% and 60% were positive with Cobas, M2000, Panther and GeneXpert assay, respectively. Regarding the 70 HIV-1/O dilutions, only 46%, 9%, 3% and 0% were positives with Cobas, Panther, M2000 and GeneXpert assay, respectively.

Conclusions: The four assays exhibited very good performances regarding HIV-1/M intragroup diversity, except one major underquantification for GeneXpert system. The quantification of the HIV-1/O strains was much more problematic with moderate correlation between the assays and a decreased sensitivity.

Abstract 4729

**Personalised prediction with machine learning approach to predict candidaemia in medical wards**

Andrea Ripoli1, Emanuela Sozio2, Francesco Sbrana3, Giacomo Bertolino4, Carlo Pallotto5, Simone Meini6, Bruno Viaggi7, Gianluigi Cardinali8, Carlo Tascini*9

1Bioengineering Department, Fondazione Toscana Gabriele Monasterio, Pisa, Italy, 2North-West District, Tuscany Health Care, Spedali Riuniti Livorno, Emergency Department, Livorno, Italy, 3U.O. Lipoapheresis and Center for Inherited Dyslipidemias - Fondazione Toscana Gabriele Monasterio, Pisa, Italy, 4Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy, 5Sezione di Malattie Infettive, Dipartimento di Medicina, Università di Perugia, Perugia, Italy, 6Internal Medicine Unit, Santa Maria Annunziata Hospital, Firenze, Italy, 7Department of Anesthesia, Neuro Intensive Care Unit, Careggi Universitáral Hospital, Firenze, Italy, 8Department of Pharmaceutical Sciences-Microbiology, University of Perugia, Perugia, Italy, 9First Division of Infectious Diseases, Cotugno Hospital, Azienda Ospedaliera dei Colli, Napoli, Italy

**Background:** Candidemia is a highly lethal infection associated with mortality rates between 40 and 60%; recently several studies have shown an increasing number of candidemic patients admitted to medical wards. Prompt and accurate diagnosis of invasive fungal infection is crucial, so that appropriate antifungal therapy can be started rapidly. Aim of this work was to assess predictive performance of a random forest algorithm for early detection of candidemia in the medical ward.

**Materials/methods:** A set of 42 potential predictors was acquired in a sample of 295 patients (male: 142, 48%; age: 72±15 years; candidemia: 157, 53%; bacteremia: 138, 47%). Using ten-fold cross-validation, a random forest algorithm, with 150 different combinations of its 3 hyperparameters, and two different sets of predictor variables, was compared with a classic stepwise multivariable logistic regression model; discriminative performance was assessed by C-statistics, sensitivity and specificity, while calibration was evaluated by Hosmer-Lemeshow test.

**Results:** The best tuned random forest algorithm demonstrated excellent discrimination (C-statistics = 0.87 ± 0.003, sensitivity = 84.24% ± 0.67%, specificity=91% ± 2.63%) and calibration (Hosmer-Lemeshow statistics = 12.779 ± 1.369, p = 0.120), markedly greater than the ones guaranteed by the classic stepwise logistic regression (C-statistics = 0.829 ± 0.011, sensitivity = 80.21% ± 1.67%, specificity = 84.81% ± 2.68%; Hosmer-Lemeshow statistics = 38.182 ± 15.983, p<0.001). Random forest, in addition to using a greater number of variables, suggests a major role of in-hospital antibiotic treatment with microbioma highly impacting antimicrobials (MHIA) that are found as a fundamental risk of candidemia, further enhanced by TPN. When in-hospital MHIA therapy is not performed, PICC is the dominant risk factor for candidemia, again enhanced by TPN. When PICC is not used and MHIA therapy is not performed, the risk of candidemia is minimum, slightly increased by in-hospital antibiotic therapy.

**Conclusions:** Random forest accurately estimates the risk of candidemia in patients admitted to Internal medical wards, allowing to take advantage of the ever-increasing amount of data collected in the electronic health records. Machine learning technique might help to identify septic patients at high risk of candidemia, reduce the delay in empirical treatment and improve appropriateness.

Abstract 4730

Vitamin D3 supplementation with a daily dose of 400 or 1200 IU results in similar antibody concentrations to measles, mumps and rubella in vaccinated 2-year-old Finnish children

Merit Melin*, Nina Ekström, Mia Kontio, Jenni Rosendahl, Saara Valkama, Elisa Holmlund-Suila, Maria Enlund-Cerullo, Helena Hauta-Alus, Timo Hytinantti, Heli Viljakainen, Sture Andersson, Otto Helve

1Finnish Institute for Health and Welfare, Helsinki, Finland, 2University of Helsinki and Helsinki University Hospital, Helsinki, Finland, *Folkhälsan Research Center, Helsinki, Finland

Background: Vitamin D3 supplementation is presently recommended to Finnish children from 2 weeks of age as a dose of 400 IU/day. The aim of this study performed in 2013-2016 was to assess if a higher dose of vitamin D3 in early childhood affects the antibody concentrations to the measles, mumps and rubella (MMR) vaccine.

Materials/methods: Children participating in the study were randomized (1:1) to receive a daily dose of 400 or 1200 IU of vitamin D3 between 2 weeks and 2 years of age. Serum 25-hydroxyvitamin D [25-(OH)D] -concentrations were measured at 12 and 24 months of age. In a sub study, the effect of vitamin D dose on humoral immunity has been assessed by measuring antibodies to vaccines included in the national immunization program. IgG antibodies to measles, mumps and rubella were measured with enzyme immunoassay from serum samples collected at 24 months of age. All the children included in the analysis (n=144 in the 400 IU and n=136 in the 1200 IU group) had received a single dose of MMR between the age of 11 and 19 months.

Results: Geometric mean IgG concentrations did not differ between the children who received 400 vs 1200 IU vitamin D3 supplementation to measles (2700 vs 2600 mIU/ml), mumps (790 vs 840 mIU/ml) or rubella (63 vs 71 IU/ml). The proportion of seropositive sera was equally high in both study groups. Antibody concentrations at 24 months of age did not correlate with serum 25(OH)D –concentrations (range 47-213 nmol/l) at 12 or 24 months of age. Only two children at 12 months and one at 24 months had serum 25(OH)D –concentrations below 50 nmol/l, which is considered to indicate a sufficient level.

Conclusions: Vitamin D3 supplementation in a higher dose had no significant effect on the measured antibody concentrations to the MMR vaccine antigens. Also, antibody concentrations at 24 months were not associated with circulating vitamin D3 concentrations at the same time point, or at the time of vaccination. Additional vitamin D3 supplementation in vitamin D3 sufficient children provides no further benefit for humoral immunity to the live attenuated vaccine.

A novel deep sequencing platform for genotyping and drug resistance detection of Mycobacterium leprae

Sofie Braet*, Philip Noel Suffys², Sidra Ezidio Gonçalves Vasconcellos², Gaëlle Bisch³, Alice Ferre³, Epco Hasker¹, Younoussa Assoumani⁴, Aboubacar Mzembaba⁴, Philip Supply⁵, Bouke De Jong¹

¹Institute of Tropical Medicine Antwerp, Antwerpen, Belgium, ²Fiocruz, Rio de Janeiro, Brazil, ³Genoscreen, Lille, France, ⁴Action Damien Comores, Moroni, Comoros, ⁵Université de Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, Lille, France

Abstract third-party references: R2STOP, EDCTP

Background: Diagnostics and surveillance of antimicrobial resistance are particularly problematic in mycobacterial diseases, linked to the biology of the pathogens involved. Among these, M. leprae can be considered the most challenging as it is not culturable and extremely clonal. In order to circumvent these problems, a culture-free assay, based on deep sequencing of a single hi-plex amplification test for M. leprae (named Deeplex-MycLep), was developed by Genoscreen in collaboration with ITM and Fiocruz.

Materials/methods: The assay queries 42 targets in one reaction. The assay includes 18 SNP target regions for determining SNP-(sub)types combined with 17 VNTR regions for higher resolution genotyping, six main drug resistance associated gene regions, in addition to the hsp65 gene for speciation.

Results: As a proof-of-principle, 15 DNA extracts from biopsies of multibacillary patients dispersed across the island of Anjouan were tested. The prototype detected 12 different genotypes [2 SNP types and 12 different Multi-Locus VNTR Analysis (MLVA) patterns], with village level clustering [two pairs from two villages with identical genotypes], and without any drug resistance mutations [Fig. 1]. Results from extended assay validation and from analysis of 332 samples from multibacillary patients recruited in the Comlep study [Comoros] will be presented.

Conclusions: The use of this amplification assay before Next Generation Sequencing allows unique target enrichment directly on clinical samples, containing also an estimated 99.9% host DNA. Translation of multiple known hypervariable region-based typing from MLVA and drug resistance-related targets onto this platform will likely result in more robust tracking of leprosy transmission and more comprehensive drug resistance surveillance datasets. In addition to high throughput capacity, Deeplex-MycLep also provides enhanced sensitivity to detect minority populations of emerging resistant bacilli or mixed infection with multiple strains.

Figure 1: Neighbour-joining tree based on the SNP and VNTR typing of M. leprae biopsy samples from leprosy patients on the Comoros [2017] in relation to their resident village.

First study on Giardia intestinalis assemblages in Algerian individuals

Salem Belkessa1,2, Daniel Vincent Thomas López3,4, Henrik Vedel Nielsen1, Karim Houali1, Farida Ghalmi5, C. Rune Stensvold*3

1Mouloud Mammeri University of Tizi Ouzou, Tizi Ouzou, Algeria, 2Mohamed Khider University of Biskra, Biskra, Algeria, 3Statens Serum Institut, Copenhagen, Denmark, 4European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden, 5École Nationale Supérieure Vétérinaire d’Alger, Algiers, Algeria

Background: Giardia intestinalis is a common flagellate parasitizing the gastrointestinal tract of humans and animals. This study investigated the occurrence of G. intestinalis in enteroparasite-positive children and adults in Algeria, and is one of only few studies to date with molecular epidemiology data on Giardia infections in Africa.

Materials/methods: A community-based cross-sectional study was carried out in two hospitals in Algiers and two in Biskra. Faecal samples from 119 individuals suspected of intestinal parasitosis and scored enteroparasite-positive by microscopy (i.e. positive for Giardia and/or other parasites) were screened by qPCR for G. intestinalis. Positive samples were subsequently assemblage-typed using nested PCR for the triose phosphate isomerase gene (tpi). The 119 study individuals comprised 55 children, 37 adults, and 27 individuals of undetermined age (Table). Median age of those with known age was 8 years (interquartile range=4.25–24, range, 2–74).

Results: Of the 119 samples, 80 (67%) were qPCR-positive; 66 were positive by both microscopy and qPCR (mean Ct value, 27.5) and 14 were negative by microscopy but positive by qPCR (mean Ct value, 30.2). The remaining 39 samples were qPCR-negative, 32 of which were negative also by microscopy. More children (45/55, 82%) were infected than adults (11/37, 30%) (P<0.0001). Samples with Ct values <30 were submitted to typing and so, for 48 of 49 positive samples (mean Ct value, 24.5), the tpi gene was successfully amplified and sequenced (Table). Assemblage A was found in 10 children, 6 adults and 6 of undetermined age. Assemblage B was found in 15 children, 6 adults and 6 of undetermined age. Neither Giardia infection overall nor specific assemblage appeared to be associated with gender; meanwhile, assemblage B appeared more common in children than in adults.

Conclusions: Most of the enteroparasite-positive children had G. intestinalis, and children were more commonly infected by this parasite than adults. It appears likely that assemblage B is more common in children than in adults in this region. Robust amplification and sequencing of the tpi gene is feasible when highly positive samples are used.

Abstract 4734

**Antibacterial activity of aztreonam-epigallocatechin gallate combinations versus multidrug-resistant strains of Acinetobacter baumannii**

Jonathan Betts¹; Kai Lucassen²; Javier Salguero-Bodes³; Michael Hornsey¹; Harald Seifert¹; Roberto La Ragione¹; Paul G. Higgins*⁴,⁵

¹University of Surrey, School of Veterinary Medicine, Guildford, United Kingdom, ²University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, ³Public Health England, Porton Down, United Kingdom, ⁴German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, ⁵University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany

**Background:** Acinetobacter baumannii is an important nosocomial pathogen, often innately multidrug-resistant (MDR) and frequently associated with severe and difficult to treat infections. With the lack of anti-Gram-negative antibiotics under development, novel therapies are urgently required, to support existing drugs, or to increase their useful lifespan. Polyphenols, such as epigallocatechin gallate (EGCG), have previously shown to be synergistic with antibiotics such as aztreonam. This study aimed to determine if EGCG was able to restore the activity of aztreonam against MDR strains of *A. baumannii* in vivo and highlight potential mechanisms of action.

**Materials/methods:** Sixteen MDR clinical *A. baumannii* isolates were used to determine the in vivo efficacy of aztreonam-EGCG combinations versus monotherapy in the *Galleria mellonella* model of infection. Larval morbidity and mortality were scored over 96 h. Histopathology was undertaken to determine detailed pathological effects of the therapies on the infected larvae. To elucidate possible mechanisms of action, expression of LacZ under control of promoters for RND-type efflux pumps, outer membrane pores and their regulators, was determined using the β-galactosidase assay on solid media. Bacterial motility assays were undertaken on motility plates supplemented with increasing concentrations of EGCG.

**Results:** Synergy between aztreonam and EGCG was confirmed in vivo, with morbidity and mortality significantly reduced in the group treated with the combination versus monotherapy. Histopathology also revealed that haemocyte clustering and bacteria adipose bodies were far lower in larvae treated with the combination. Results from the β-galactosidase assay indicated that EGCG inhibited the expression of *adeRS; adeABC; adeI; adeF and oprD* and also inhibited bacterial motility at 2 mg/L, without impeding sessile growth.

**Conclusions:** Results from our investigations not only demonstrate that EGCG increases the activity of aztreonam in vivo against MDR strains of *A. baumannii*, but also highlights possible mechanisms of action, including effects on antimicrobial resistance (reduced efflux) and virulence factors, which likely increase the effectiveness of the aztreonam. This combination shows potential to treat infections caused by MDR *A. baumannii*.

1Inserm, Infection Antimicrobials Modelling Evolution, Paris, France; 2Bichat-Claude Bernard Hospital, Department of Infectious Diseases, Paris, France; 3Imperial College London, Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, London, United Kingdom; 4Antibioclic Steering Committee, Paris, France; 5University of Paris, Department of General Medicine, Paris, France

Abstract third-party references: Supported by Antibioclic

Background: In Europe, 80-90% of all antibiotics used in humans are prescribed in primary care by General Practitioners (GP). Suboptimal use of antibiotics is a driver of antimicrobial resistance (AMR) and clinical decision support systems (CDSS) for antimicrobial prescribing have been devised to improve antimicrobial use. However, many CDSS failed to demonstrate a clinical impact because of a low uptake and poor sustainability. The aim of this study is to identify the determinants of the long-term adoption of a CDSS for antimicrobial prescribing by exploring the use of Antibioclic in primary care.

Materials/methods: We interviewed French GPs about their use of Antibioclic, a CDSS for antimicrobial prescribing in primary care. Antibioclic is a publicly funded freely available CDSS targeting 37 infectious diseases, used by more than 5000 GPs daily. The participants were recruited through the mailing list of Antibioclic or at a course of antimicrobial prescribing. Interviews were recorded, transcribed and coded using NVivo 12 and were conducted until data saturation. Data were analysed using classic grounded theory approach.

Results: There were 22 interviews with GPs, 15 women and 7 men, median age 40 [IQR, 33-44] years, median duration of practice 7 years [IQR, 3-12]. All the participants had a frequent [several times a week] and sustainable [for more than one year] use of the CDSS in their practice. Antibioclic was the most used CDSS across disciplines for all the GPs. We identified 7 key themes that explained the sustainable adoption of the CDSS: usability, confidence, routinization, convenience, improvement of practices, contextualized learning and the lack of negative consequences. The GPs pointed out the importance of co-design between engineers and primary care prescribers for the development of a CDSS. They also discussed the discrepancy between guidelines and daily clinical practice, the role that CDSS play in continuing medical education and the evolution of the doctor-patient relationship.

Conclusions: This study provided valuable information on the determinants of the long-term adoption of a CDSS for antimicrobial prescribing in primary care. The themes that we identified may relate to a broad spectrum of electronic tools in healthcare.

Abstract 4741

Hepatitis E virus infection is a risk for liver transplant recipients in Sweden

Miriam Karlsson*1,2, Catarina Skoglund3,4, Marie Karlsson1, Martin Lagging1,5, Maria Castedal3,4, Heléne Norder1,5

1Sahlgrenska Academy, University of Gothenburg, Institute of Biomedicine, Department of Infectious Diseases, Gothenburg, Sweden, 2Region Västra Götaland, Södra Älvsborg Hospital, Department of Infectious Diseases, Borås, Sweden, 3Sahlgrenska University Hospital, The Transplant Institute, Department of Surgery, Gothenburg, Sweden, 4Sahlgrenska Academy, University of Gothenburg, Institute of Clinical Sciences, Gothenburg, Sweden, 5Region Västra Götaland, Sahlgrenska University Hospital, Department of Clinical Microbiology, Gothenburg, Sweden

Background: Liver-transplant recipients with acute hepatitis E virus (HEV) infection are at risk developing a chronic infection, which may rapidly progress to severe liver damage if not treated. However, the prevalence of HEV infection after liver transplantation remains to be elucidated, and likely varies geographically. Thus, the aim of this study was to investigate the prevalence of acute and chronic HEV infection among liver transplant recipients in a highly HEV endemic region.

Materials/methods: During 2013-2018, 116 liver-transplant recipients were prospectively enrolled. They were evaluated for anti-HEV IgM and IgG antibodies, as well as HEV RNA at the time of liver transplantation, and 3 and 12 months post-transplantation. Additionally, medical records were reviewed.

Results: Eleven (9%) liver transplant recipients acquired HEV infection during the study period. One patient had an ongoing infection prior to liver transplantation that had resolved without treatment at follow-up, six patients acquired early infections detected at the 3 month follow-up sampling, and four showed signs of infection at the follow-up 12 months post-transplantation. Seven (6%) had detectable HEV RNA, and additionally 4 (3%) patients had serological markers indicative of HEV infection without detectable HEV RNA. Signs and symptoms of HEV infection were subtle, none were diagnosed in routine clinical care, and none developed a chronic HEV infection. Furthermore, 15 patients (13%) had reactive anti-HEV IgG serologies in pre-transplant samples.

Conclusions: A substantial proportion of liver transplant recipients in Sweden are at risk of acquiring acute HEV infection, both before and after transplantation. Surprisingly, no chronic HEV infection were detected in the present study. As HEV infections are often discrete and not diagnosed by current clinical practise, and as ribavirin therapy is available, the introduction of routine prospective HEV RNA screening of liver transplant recipients may be warranted.

Abstract 4742

**Genomic analysis of *Bordetella* pertussis strains causing disease in Italy and in Argentina, 2013 - 2016**

Luigina Ambrosio*, Gabriele Buttinelli, Carlo Concato, Giulia Linardos, Pasqualina Leone, Ilaria Schiavoni, Daniela Bottero, Giorgio Fedele, Daniela Hozbor, Paola Stefanelli

1Istituto Superiore di Sanità, Dept. Infectious Diseases, Rome, Italy, 2Bambino Gesù Children’s Hospital, IRCCS, Virology Unit, Rome, Italy, 3Bambino Gesù Children’s Hospital, IRCCS, Multifactorial Disease and Complex Phenotype Research Area, Rome, Italy, 4Universidad Nacional de La Plata, Instituto de Biotecnología y Biología Molecular, Facultad de Ciencias Exactas, La Plata, Argentina

**Background:** Antigenic divergences among *Bordetella pertussis* strains have been described mainly in countries where acellular pertussis vaccines are widely used, leading to the supposition that the bacterial population could adapt to substantial vaccine-induced immune pressure.

Here, we compared the genetic characteristics of *B. pertussis* strains isolated between 2013 and 2016 in Italy and in Argentina, two countries that have adopted different types of pertussis vaccines and different vaccination schedules.

**Materials/methods:** Whole-genome sequencing (WGS) on the Illumina MiSeq platform was used to analyze 55 genomes of *B. pertussis* strains mostly isolated from infants less than 1 year of age, from 2013 to 2016: 38 from Italy, where acellular pertussis vaccine for primary vaccination series is currently in use, and 17 from Argentina, where whole-cell pertussis vaccine for primary vaccination series is currently in use. *De novo* assembled genomes were analyzed by multilocus antigen sequence typing (MAST) and multilocus variable-number tandem repeat analysis (MLVA). Genetic relationship between the isolates were resolved into Neighbor-Net networks based on the core genome multilocus sequence typing scheme [cgMLST, https://bigsdb.pasteur.fr].

**Results:** Among the Italian isolates, the most common MAST profile was the *ptxP3/ptxA1/prn2/fim2-1/fim3-1* (82%). Sixty-two percent of the isolates resulted pertactin-deficient (*PRN*-) mostly due to the insertion of the *IS481* element (52%), followed by the introduction of a premature stop codon (39%) and the disruption of the promoter region (9%).

Ninety-four percent of the Argentine isolates belonged to the *ptxP3/ptxA1/prn2/fim2-1/fim3-2* profile. *PRN* isolates represented the 6% of the total and were exclusively due to the *IS481* insertion.

In both countries, the MLVA Type MT27 represented the majority of the isolates (>75%).

The cgMLST analysis showed a geographic clustering.

**Conclusions:** These preliminary results suggest that the use of different pertussis vaccines in the pediatric setting (acellular in Italy and whole-cell in Argentina) may exert a selective pressure favoring the prevalence of different circulating genotypes at least among strains causing disease in infants.

Abstract 4743

Comparison of three commercial sample-to-result platforms to an established real-time PCR assay for the detection of herpesviruses in cerebrospinal fluid

Rob Schuurman1, Edwin Fries*1, Serif Safak2, Nienke Leonie Plantinga2

1UMC Utrecht, Utrecht, Netherlands

Background: Herpes simplex viruses (HSV) and Varicella Zoster Virus (VZV) are major causes of viral encephalitis. Rapid and sensitive diagnosis in CSF is of great importance for early and adequate treatment of patients with a suspect of herpesvirus encephalitis. Real-Time PCR to detect HSV1&2 and VZV is the gold standard to diagnose herpes meningitis/encephalitis. In this study, we compared three sample-to-result systems to an established Laboratory Developed Test (LDT) to detect HSV1&2 and VZV in CSF, focusing on clinical and analytical sensitivity, CSF volume, assay turnaround and hands on times.

Materials/methods: The study involved the ARIES® M1 (Luminex), LIAISON MDX® (Diasorin Molecular) and Ingenius (Elitech) systems using the respective dedicated diagnostics reagents validated for CSF. Routine LDT for the detection of HSV1&2 and VZV in CSF was considered the gold standard. Analytical sensitivities were compared using 5-fold dilution series of cultured viral stocks.

Clinical validation involved 22 retrospective CSF specimens, positive for one pathogen and serving as a negative for the others. Moreover, 20 HSV1&2 and VZV proficiency panel samples (QCMD 2018) were included.

Results: Analytical sensitivity experiments demonstrated comparable sensitivity between the sample to result systems and a maximum 5-fold reduced sensitivity compared to the LDT. Proficiency panel results for HSV1/2 and VZV demonstrated complete correctness for all commercial assays, except for one VZV sample which tested negative for ARIES®M1. Clinical validation experiments demonstrated full agreement with LDT for both the Ingenius and LIAISON MDX® HSV1/2 and VZV assays. Two clinical samples tested negative for HSV-1 in the ARIES®M1. No false positive results were observed in any assay. Assay turnaround time/sample volume for the Ingenius, ARIES® M1 and the LIAISON MDX® were 139 minutes/200µL, 245 minutes/400µL and 60 minutes/50µL, respectively.

Conclusions: The performances of the LIAISON MDX® and Ingenius systems for detection HSV1&2 and VZV in suspected viral meningitis/encephalitis patients were comparable to LDT, whereas the ARIES® M1 missed one clinical HSV-1 positive sample and one VZV positive QCMD sample. Major differences were observed required sample volumes per assay and in assay turnaround times, which were both in favor of the LIAISON MDX®.

Abstract

Background: Klebsiella pneumoniae bloodstream infections (BSIs) occur worldwide with varying mortality. Resistant strains, like those producing extended-spectrum beta-lactamases (ESBL) and carbapenemases, are becoming increasingly common, especially in hospital settings, posing therapeutic challenges. We aimed to study factors associated with BSIs caused by antibiotic-resistant Klebsiella pneumoniae, in the largest tertiary hospital of the Republic of Cyprus.

Materials/methods: The study involved patients with BSI due to Klebsiella pneumoniae, who were hospitalized in Nicosia General Hospital between January 2014 and December 2018. Data on demographics, co-morbidities, prior hospitalization, prior ICU-admission, previous antimicrobial use, nosocomial acquisition, the presence of prosthetic device or surgery, and primary site of infection were retrospectively recorded. Associations between ESBL Klebsiella pneumoniae BSIs and factors/covariates were examined using logistic regression. Chi-squared tests and t-tests were used to explore associations between carbapenem-resistant (CR) K. pneumoniae BSIs and factors/covariates. Statistical analysis was performed in R.

Results: The study involved 175 patients with BSI caused by Klebsiella pneumoniae. Of these, 61 BSIs were caused by ESBL strains, 101 by non-ESBL and 13 by CR strains. In univariable analyses, age, sex, heart disease, antimicrobial use during current admission, previous hospitalization (ward or ICU) and primary BSI were associated with an ESBL strain. Antibiotic use during current admission [Odds Ratio (OR) 5.63, Confidence Interval (CI) 2.1 - 17] and heart disease (OR 4.72, CI 2.23- 10.5) sustained significant association with ESBL Klebsiella pneumoniae BSI in multivariable models. Antibiotic use during current admission (p 0.008), respiratory infection (p 0.03), and recent history of surgery (p 0.04) were more prevalent among CR K. pneumoniae BSI patients than among non-CR K. pneumoniae BSI patients. There were no significant differences between patients with CR K. pneumoniae BSI and those with BSI due to an ESBL strain.

Conclusions: This is the first study in Cyprus that explored factors associated with ESBL and CR Klebsiella pneumoniae bloodstream infections. Findings of the analyses including associations of recent antimicrobial use and heart disease with BSI due to ESBL producing K. pneumoniae, should inform clinical practice in hospital settings.

Stability studies with tigecycline in bacterial growth medium and impact of stabilising agents: a prerequisite for in vitro susceptibility testing

Lisa Franziska Amann*, Emilia Ruda Vicente, Mareike Rathke, Astrid Broeker, Sebastian Wicha

University of Hamburg, Dept. of Clinical Pharmacy, Institute of Pharmacy, Hamburg, Germany

**Background:** Tigecycline is used in patients with life-threatening infections and hence knowledge about bacterial susceptibility is key for therapeutic decisions. Medium-age related effects on tigecycline stability were described, which led to inconsistencies in tigecycline MIC values. The aim of this study was (i) to examine the degradation process of tigecycline over time, and (ii) to evaluate the effect of the antioxidants ascorbic acid and sodium pyruvate on tigecycline stability, which were recently recommended to stabilize tigecycline infusion solutions, but had not been tested in bacterial growth medium.

**Materials/methods:** Tigecycline in aged (7 days) and fresh cation-adjusted Mueller Hinton Broth (ca-MHB) using no stabilizing agent, ascorbic acid (0.3%), or pyruvate (1%) was incubated for 24 h at 37 °C. Stability was evaluated using high-performance liquid chromatography and time-kill studies with *Staphylococcus aureus* (ATCC 29213) were conducted to evaluate the potential impact of the antioxidants on bacterial growth and kill.

**Results:** Degradation of tigecycline was dependent on ca-MHB age. In fresh ca-MHB tigecycline remained stable 99.6% (94.5% – 103.5%, p = 0.412), whereas degradation to 80.1% (82.8% – 75.6%, p = 2.44·10^{-6}) was measured within 24 h in seven days aged broth. Using fresh ca-MHB, > 1-log killing was observed (Figure 1A), while at 1x MIC in aged ca-MHB no killing but a 1-log growth was observed after 24 h (Figure 1B). Ascorbic acid in ca-MHB caused rapid degradation to 4.7% (5.1% – 3.5%, p = 2.47·10^{-6}) and resulted in loss of antibacterial activity (Figure 1C). Sodium-pyruvate (1%) in ca-MHB stabilized tigecycline in 7 days aged ca-MHB at 37 °C (94.8% – 95%, p = 1.56·10^{-3}) and the growth and killing pattern was similar to fresh broth, but independent of ca-MHB age (Figure 1D).

**Conclusions:** Our results underline the importance of using fresh ca-MHB or the need to stabilize tigecycline for susceptibility testing. Ascorbic acid, although recommended to stabilize tigecycline infusion solution, was found not suitable to stabilize ca-MHB. Sodium-pyruvate was found to stabilize tigecycline and represents an inexpensive option to streamline the susceptibility testing of tigecycline.

**Figure 1:** Time-kill studies of *Staphylococcus aureus* in (A) freshly prepared and (B) seven days aged cation-adjusted Mueller-Hinton broth and supplemented broth containing (C) 0.3% ascorbic acid or (D) 1% sodium-pyruvate.

Detection of virulence genes and capsule types in *Klebsiella pneumoniae* isolated from blood cultures in patients with haematological malignancies

Svetlana Khrulnova*1, Anna Korobova2, Anastasia Fedorova Mironova1, Irina Frolova3, Galina Klyasova1

1National Research Center for Hematology, Moscow, Russian Federation

**Background:** *Klebsiella pneumoniae* is one of the most important pathogens responsible for serious infections such as bacteremia, pneumonia, intra-abdominal infections and urinary tract infections. Nosocomial isolates are often associated with extended-spectrum β-lactamases (ESBL) and carbapenemases. However, recently there have been many reports on the hypervirulent *K.pneumoniae* (hvKp) that draws more and more attention. The aim of this study was to evaluate the presence of hypervirulent strains among *K.pneumoniae* isolated from blood cultures in patients with haematological malignancies.

**Materials/methods:** In the current prospective multicenter study we analyzed *K.pneumoniae* isolated from blood cultures in haematological patients in 12 Russian hospitals (2003-2018). Antimicrobial susceptibility was determined by the broth microdilution method [CLSI, 2018]. Carbapenemase genes (*bla*OXA-48-like, *bla*KPC-like, *bla*NDM-like, *bla*VIM-like and *bla*IMP-like) were detected by multiplex real-time PCR. Genetic markers for hypervirulence (*iucA, rmpA, rmpA2*) were detected by PCR. Multiplex PCR was performed to detect for K1, K2, K5, K20, K54, and K57 serotype-specific alleles, that are commonly used as markers for hvKp strains.

**Results:** A total of 494 *K.pneumoniae* were examined. Of those, 83(16.8%) were carbapenemase-producing *K.pneumoniae* (CP-*K.pneumoniae*), 261(52.8%) were ESBL-producing *K.pneumoniae* (ESBL-*K.pneumoniae*, without CP-*K.pneumoniae*) and 150(30.4%) were susceptible *K.pneumoniae* (without CP- and ESBL-*K.pneumoniae*). Among these 494 isolates, 108(21.9%) carried at least one virulence gene (*iucA, rmpA or rmpA2*). These isolates were considered hvKp. The virulence genes were prevalent in CP-*K.pneumoniae* (n=40;48.2%) while among ESBL-*K.pneumoniae* and susceptible *K.pneumoniae* these genes were detected in 17.2%(n=45) and 15.3%(n=23) isolates, respectively [Table]. The virulence genes were presented both in different combinations with each other and in combination with the markers associated with the studied capsule types (n=93;86.1%). Serotype-specific alleles (K1, K2, K5, K20, K54, and K57) were detected in 117(23.7%) isolates *K.pneumoniae* [Table]. Only two (K2 and K57) capsule types were identified in CP-*K.pneumoniae* while in susceptible and ESBL-*K.pneumoniae*, respectively five and four different capsule types, were detected. The virulence genes were not presented in more than a half of the isolates (51.3%) with identified capsule types.

**Conclusions:** This study revealed that 21.9% *K.pneumoniae* isolated from blood cultures carried the virulence genes. The high percentage of the virulence genes (*iucA, rmpA, rmpA2*) among CP-*K.pneumoniae* (48.2%) is especially alarming.

In vitro activity of beauvericin against Sarcoptes scabiei: may a mycotoxin help for the control of scabies?
Charbel Al Khoury1,2, Nabil Nemer1, Georges Nemer1, Mazen Kurban4, Charlotte Bernigaud2,5, Katja Fischer6, Jacques Guillot*2
1Kaslik, Faculty of Agricultural and Food Sciences, Jounieh, Lebanon, 2Paris 12 Val de Marne University, Ecole nationale vétérinaire d’Alfort, EA Dynamyc, Maisons-Alfort, France, 3American University of Beirut, Department of Biochemistry and Molecular Genetics, Beirut, Lebanon, 4American University of Beirut, Department of Dermatology, Beirut, Lebanon, 5Paris 12 Val de Marne University, Faculty of Medicine, Department of Dermatology, Créteil, France, 6QIMR Berghofer Medical Research Institute, Scurabies laboratory, Brisbane, Australia

Background: Scabies is a frequent cutaneous infection caused by the mite Sarcoptes scabiei in a large number of mammals including humans. Current therapeutic options are not optimal and there is an unmet need for new acaricide molecules with greater efficacy and improved pharmacological profiles. The entomopathogenic fungus Beauveria bassiana is known to produce beauvericin, a secondary metabolite belonging to the enniatin antibiotic family. Beauvericin was proven to have many biological effects including insecticidal, antitumor, antibacterial, and antifungal activity. The objective of the study was to assess the activity of beauvericin against different evolutive stages of S. scabiei.

Materials/methods: S. scabiei mites and eggs were collected from experimentally-infected pigs. For in vitro evaluation of acaricide activity, motile stages (adults, nymphs/larvae) or eggs were placed in Petri dishes filled with Columbia agar supplemented with pig serum and different concentrations (0.5, 5, and 50 µM) of the drugs to be tested. Mites were inoculated in the middle of the plates and examined at 1, 2, 3, 4, 5, 6, 7, 8 and 24h after inoculation for survival assessment of motile stages at room temperature. Mites were considered dead when no movement occurred under the microscope during 5 min. To assess the activity against S. scabiei eggs, Petri dishes were maintained at 37°C for 5 days to promote egg development. Lethal time (LT50) necessary to kill half of the mites population was calculated using the probit regression analysis in SPSS software.

Results: Beauvericin, dimpylate, and ivermectin were highly efficient against S. scabiei motile stages. The lowest LT50 values (1.1 and 1.0h) were observed with a concentration of 50 µM of dimpylate and ivermectin against females and nymphs/larvae, respectively. The highest LT50 values (5.6 and 4.7h) were observed with a concentration of 0.5 µM of beauvericin and dimpylate against females and nymphs/larvae, respectively. Beauvericin showed higher activity against adults and eggs of S. scabiei when compared to dimpylate and ivermectin.

Conclusions: These preliminary results indicated that beauvericin may be considered as a new scabicide molecule. Further studies assessing the possibility of beauvericin application to treat scabies in humans or sarcoptic mange in animals are required.

Abstract 4750

Predictive value of CD4+ T helper lymphocytes, associated biomarkers and procalcitonin in the prognostication of polytrauma patients with sepsis

Surbhi Khurana1*, Purva Mathur1, Nidhi Bhardwaj1, Subodh Kumar1, Sushma Sagar1, Richa Aggarwal1, Kapil Dev Soni1, Rajesh Malhotra1

1All India Institute of Medical Sciences, New Delhi, Delhi, India

Background: Trauma is a growing epidemic worldwide which mainly targets the young and productive population and imposes a major burden on the health infrastructure to provide emergency and often-prolonged trauma care. A high percentage of polytrauma patients develop a post-trauma complication-sepsis that can lead to increased morbidity and mortality. This study was conducted to elucidate their unique immunological profile governed by CD4+ T helper (Th) lymphocytes & biomarkers, to ultimately salvage these critically ill trauma patients.

Materials/methods: Fifty polytrauma ICU-patients with sepsis and 50 controls (40 healthy-controls & 10 diseased-controls) were included in the study conducted at JPNA Trauma Centre, AIIMS, New Delhi. Peripheral blood samples were obtained on day 0: first laboratory confirmed bloodstream infection (BSI), day 4 (post-culture based antimicrobial treatment), day 10 and day of discharge (DD). Multi-colour flowcytometry was used to study the intracellular profiles of 12 circulating CD4+ T helper subsets (IFN-γ+Th-1, IL-4+Th-2, IL-9+Th-9, IRF4+Th-9, IL-17A+Th-17, RORγT+Th-17, IL-22+Th-22, IL-10+ Tr1, TGF-β+Th-3, C-D25+FoxP3+nTreg, and FoxP3+iTreg cells), 14 serum cytokines (sIFN-γ, sTNF-α, sIL-2, sIL-4, sIL-5, sIL-6, sIL-9, sIL-10, sIL-13, sIL-17A, sIL-17F, sIL-21, sIL-22, and sTGF-β), and serum procalcitonin (PCT). The data were statistically analyzed based on disease progression and their clinical outcome.

Results: Of the total 50 patients 25 (50%) patients were microbiologically cured and 20 (40%) had a fatal outcome. Majority 38 (76%) were males and developed sepsis 11.9 ± 8.2 days post-trauma. The percentages of Th-9, nTreg and Th-3 were higher in patients than controls. Figure 1 shows the statistically significant elevation & depression of all the markers in mid (day 4) & late (day 10) phase in patients who were microbiologically cured (who had a subsequent sterile blood culture) and those who had a fatal outcome. A very high and persistent serum PCT may be an indicator of poor prognosis. By DD the levels of CD4+ Th cells & biomarkers were comparable to those in healthy controls. All the patients were clinically followed up till their outcome at the hospital.

Conclusions: This study is based on a multi-marker (n=27) approach to identify predictive immunological markers in diagnosis and prognosis of polytrauma patients developing sepsis. It has laid a foundation for further detailed studies with more stringent inclusion criteria which would ultimately lead to the development of a definitive scoring system for prediction of sepsis progression and unfavorable outcome.

Abstract 4753

Changes occurred in immunological and molecular determinations of toxoplasmosis in pregnancy and newborn children

Claudia Istrate*, Carmen-Michaela Cretu1,2,3, Patricia Mihailescu1,4

1EcoParaDiagnosis Medical Center, Bucharest, Romania, 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, 3Colentina Hospital, Bucharest, Romania, 4Faculty of Biology, Bucharest, Romania

Background: Toxoplasmosis is one of the most prevalent parasitic disease. The etiological agent - an obligate intracellular protozoan. The life cycle involves a definitive host (Felidae) and a wide range of intermediate hosts. Sexual reproduction: in the body of the definitive host who eliminates in the external environment the unsporulated oocysts. The asexual phase: in the body of the intermediate host, resulting tachyzoites and bradyzoites.

Materials/methods: Were collected 1 789 biological materials (serum, CSF, amniotic fluid, aqueous humour) from patients with suspected toxoplasmosis. As methods: ELISA (screening) - 1623, confirmation: western blot (WB) - 80 and RT-PCR - 86. 40 pregnant patients were monitored, 26 of whom returned to birth for dynamic monitoring of the level of antibodies in the newborn, up to the age of 1 year.

Results: Of the total samples analyzed by the screening method (1623), 1115 were tested for acute phase antibodies (IgA, IgE and IgM) and 508 for chronic phase antibodies (IgG). In 40 of those who had a recent infection, the avidity test was performed, 6/40 (15%) recent infections and 34/40 (85%) late infections. All acute infections were confirmed by western blot, and RT-PCR was definitive for confirming an infection in 5 cases. Monitoring the antibodies in pregnant patients (quarterly and in dynamics), the results showed 95/320-29.68% positive for IgA, 37/639 - 5.79% for IgE, 27/116 - 23.27% for IgM and 392/508 - 77.16% for IgG. Of the mother-newborn pairs, all children presented with specific IgG-type antibodies at birth, which are transmitted passively maternal-fetal and have a titer that decreases in dynamics until the age of 1 year.

Conclusions: In the case of the diagnosis of toxoplasmosis, the laboratory methods are of major importance in monitoring the treatment and in preventing the risk of congenital transmission. Early detection of acute-phase antibodies (IgA, IgE, IgM anti-Toxoplasma gondii) in every quarter, together with molecular diagnostics (liquid, amniotic PCR, CSF, aqueous humor) allows the clinician an early diagnosis orientation and prompt establishment of an appropriate treatment which, which leads to an increase of the quality life of the patient.

Characterisation of relationships between *Staphylococcus aureus* and *Escherichia coli*, *Acinetobacter baumannii* and *Candida auris* and their implications for survival and persistence in the dry environment

Ngozi Amaeze*1, Gordon Ramage1, William Mackay1, Craig Williams1, Ryan Kean3

1Paisley Campus, University of the West of Scotland (UWS), Paisley, United Kingdom, 2Glasgow Dental Hospital and School, Glasgow, United Kingdom, 3Glasgow Caledonian University, Glasgow, United Kingdom

**Background:** Microorganisms are very diverse in their relationships with other microorganisms in the healthcare environment and these relationships may influence their survival and persistence on frequently cleaned and decontaminated dry surfaces. In this study the relationship of *S. aureus*, a frequently isolated healthcare associated infectious microorganism with other clinically relevant microorganisms such as *Escherichia coli*, *Acinetobacter baumannii* and *Candida auris* were studied.

**Materials/methods:** *S. aureus*, *E. coli*, *A. baumannii* and *C. auris* were first grown as monocultures. *S. aureus* was co-cultured with the other organisms and then as a primary or secondary coloniser with each of them. The organisms were grown in 5% tryptic soy broth at ambient temperature with sequential hydration and dehydration periods for 12 days. Biomass and cell recovery were evaluated at days 4, 6, 9 and 12 by crystal violet assay and standard plate culture.

**Results:** This study confirmed the existence of active relationships between different groups of bacteria which affected their survival and the ability to form biofilms. *S. aureus* and *A. baumannii* formed a protocooperative relationship. Biomass production increased by 19% when *S. aureus* was a primary coloniser than as a secondary coloniser. The relationship between *S. aureus* and *E. coli* was predatory resulting in reduction of biomass and cells of *S. aureus* by 58% and approximately 1.5 log10 separately. Biomass production was reduced by 21% when *S. aureus* was a secondary coloniser. *C. auris* appeared to scavenge off *S. aureus* in its effort to grow as the numbers of *S. aureus* decreased by 2 log10 while that of *C. auris* increased after 6 days of coculture by 1 log10. The position of *S. aureus* as a primary or secondary coloniser had no significant impact on biomass formation (p=0.99).

**Conclusions:** The natural interactions that exist between microorganisms affect the response of microorganisms to stressors. Cocultures of free-living organisms and biofilms may be valuable in understanding microbial persistence and tolerance to antimicrobials.

Abstract 4761

Exfoliative toxin A-producing *Staphylococcus aureus* clonal complex 8 strains causing staphylococcal scaled skin syndrome in newborns

Igor Abaev*1, Yury Skryabin1, Nadezhda Fursova1, Ivan Dyatlov1

1State Res. Ctr. for Appl. Microbial. & Biotechnol. (SRCAMB), Obolensk, Russian Federation

**Background:** Phage-encoded exotoxin genes and related clinical syndromes are associated with certain clonal complexes (CC) of *Staphylococcus aureus*. Staphylococcal scalded skin syndrome (SSSS) in newborns is mainly associated with *S. aureus* strains of CC121 and CC15 which carry the exfoliative toxin A (ETA) gene encoded Sa1int phages. We recently reported, in a study of two outbreaks of SSSS in newborns, that *S. aureus* CC8/ST2993 strains were isolated. CC8 strains were not previously associated with SSSS in newborns. We investigated ETA production and virulence of CC8/ST2993 strains, a novel causative agent of SSSS in newborns, in compare with CC15 and CC121 strains causing SSSS.

**Materials/methods:** Fully-sequenced CC8, CC15 and CC121 strains were isolated during outbreaks of SSSS in maternity hospitals in Russia. *S. aureus* strain MW2 was used as a reference control. *S. aureus* strain virulence was determined using the neonatal-mouse bioassay, a skin deep infection mouse model, and the insect infection model *Galleria mellonella*. ETA production was studied using approaches: SDS-PAGE, MALDI-TOF analysis, quantitative real-time PCR. Genome sequences of ETA-producing *S. aureus* strains and ETA-converting bacteriophages were analyzed and aligned.

**Results:** All CC8, CC15 and CC121 strains in study produced ETA as shown by a positive Nikolsky sign in the neonatal-mouse bioassay. *S. aureus* strain virulence was different depending on CC identified and animal model choice. ETA-producing CC8 strains caused open skin lesions in older BALB/c mouse model of skin deep infection. ETA amount produced by *S. aureus* strains was different depending on CC. SDS-PAGE, MALDI-TOF analysis and quantitative real-time PCR showed increased ETA levels in CC8 strains. Full genome SNP-based phylogenetic analysis revealed that ETA-producing CC8 strains were most closely related to USA300 lineage.

**Conclusions:** ETA-producing CC8/ST2993 strains, a novel causative agent of SSSS in newborns, were characterized in increased virulence compared with common *S. aureus* strains causing the infection. The result is determined probably due to increased ETA production.

**Relationship between local-area socioeconomic status and rates of bloodstream infection and *Clostridioides difficile* infection**

Simon Thelwall*, Russell Hope, Susan Hopkins

1Public Health England, London, United Kingdom

**Background:** Mandatory surveillance of key pathogens (MRSA, MSSA, *Escherichia coli*, *Klebsiella* spp. and *Pseudomonas aeruginosa*) causing bacteraemia and of *Clostridioides difficile* infection (CDI) in England shows geographic disparities in rates of infection, with rates of infection for some pathogens higher in the North of England, compared to the South. We sought to test the hypothesis that local area socioeconomic deprivation was associated with higher rates of infection for these pathogens and to examine factors driving the association.

**Materials/methods:** Cases of infection covered by mandatory surveillance occurring in 2017 were extracted from Public Health England’s (PHE) Healthcare Associated Infection Data Capture System (HCAIDCS). Information on covariates at the local area level (Clinical Commissioning Group, CCG) included prevalences of diabetes, cancer and dementia as well as antibiotic prescribing. Local area deprivation was assessed using the Index of Multiple Deprivation (IMD). Multivariable linear regression was used to assess relationships between rates of infection and deprivation at the local level.

**Results:** Age- and sex-standardised rates of infection were higher in areas with higher deprivation for *C. difficile* (rate difference (RD): 8.2, 95% CI:6.4-10.0, most deprived compared to least), *E. coli* (RD: 30.2, 95% CI:27.1-33.4), *Klebsiella* spp. (RD: 5.6, 95% CI:4.2-6.9) and MSSA (RD: 11.2, 95% CI:9.5-12.9). There was no evidence of differences in rates for MRSA (RD: 0.2, 95% CI:-0.2-0.7) or *P. aeruginosa* (RD: 0.7, 95% CI:-0.2-1.6). After adjusting for covariates, there was still strong evidence for associations between higher deprivation and rates of infection for *E. coli* ($R^2 = 0.47$, $p < 0.001$), *Klebsiella* spp. ($R^2 = 0.28$, $p = 0.002$), MSSA ($R^2 = 0.38$, $p < 0.001$) and *C. difficile* ($R^2 = 0.23$, $p < 0.001$), but no evidence for association between higher deprivation and rates of infection for MRSA ($R^2 = 0.13$, $p = 0.311$) or *P. aeruginosa* ($R^2 = 0.23$, $p = 0.167$).

**Conclusions:** After adjusting for available covariates, rates of infection with *E. coli, C. difficile*, MSSA and *Klebsiella* spp. remained associated with higher levels of local-area deprivation. There was no evidence of an association for MRSA or *P. aeruginosa*. Identifying causal factors of the association remains challenging.

Abstract 4763

**The future of hepatitis C virus nucleic acid amplification techniques standardization?**

Jacqueline Fryer*1, Peter Rigsby1, Jason Hockley1, Clare Morris1

1National Institute for Biological Standards and Control, Potters Bar, United Kingdom

**Background:** Viral load measurements by nucleic acid amplification techniques (NAT) are critical for the prevention and management of HCV infections. The International Standard (IS) for HCV NAT defines the detection and quantification specifications of these assays in terms of the International Unit (IU), thereby enabling the comparison of data generated by a broad range of assay platforms. This reference comprises HCV (genotype 1a)-positive window-period plasma which has proved difficult to source at high-titre and in large volumes. Hence, it has been replaced six times since establishment over 20 years ago. The frequency of this replacement presents problems in terms of the HCV sequence heterogenicity between different plasma sources, which can affect the RNA measurement by different NAT assays and potentially lead to drift in the value of the IU.

**Materials/methods:** Two inactivated cell cultured HCV (HCVcc) samples comprising different genotypes were included in a worldwide collaborative study towards the establishment of the 6th HCV IS, in order to evaluate their suitability as a source material for future HCV references. They were evaluated alongside two HCV plasma-derived candidates and three HCV-positive plasma samples comprising different HCV genotypes.

**Results:** The variability (SD) of HCV RNA measurements between laboratories ranged from 0.11 to 0.28 log10 IU/mL across the study samples. When potencies were expressed relative to HCV plasma candidates and HCVcc there was little change in inter-laboratory variability, suggesting that HCV NAT assays are well harmonized. The results showed that neither HCVcc sample worsened the agreement between HCV NAT-assays compared to existing HCV-plasma sources. There was no evidence for variation in the quantification of different HCV genotypes present in the study samples.

**Conclusions:** Since adoption of the IU harmonization of HCV RNA measurements has continued to improve such that existing assays can detect small changes in the value of the IU between replacement ISs. This study suggests that HCVcc could provide suitable alternative source material for this reference and would provide consistent virus for replacement batches. In addition, the ability to demonstrably inactivate HCVcc would permit increased batch sizes which are currently limited by the capacity of the infectious filling isolator at NIBSC.

Evaluation of quality indicators in Staphylococcus aureus bacteraemia in a university hospital

Sofía de La Villa Martínez*, Patricia Muñoz1, Alexi Arias1, Adriana Rojas1, Carlos Sánchez Carrillo1, Marícela Valerio Minero1, Alicia Galar Recalde1, Ana Alvarez-Uria1, Emilio Bouza Santiago1

1Gregorio Marañón Hospital, Servicio de Microbiología y Enfermedades Infecciosas, Madrid, Spain

Background: We are not aware of a simple Quality of Care Score (QCS) to assess in patients with S. aureus bloodstream infections (SA-BSI). Recently, it has been published a set of 25 quality indicators (QIs) for the management SA-BSI. Our study tried to construct a QCS in SA-BSI episodes with prognostic implications.

Materials/methods: Retrospective study in adult hospitalized patients with SA-BSI. We evaluated the demographic, clinical and follow-up variables.

We determined the frequency of compliance of the 25 QIs, evaluating three possibilities: done (+1 point), not done (-1 point) or not relevant (0 point) and made a QCS with the total addition of points obtained in each case. The maximum of points for uncomplicated SA-BSI was 15, and for complicated SA-BSI 18 points. We compared the QCS in the outcome of the disease, defined as mortality within 30 days.

Results: Between January 2018 and July 2019, we selected 99 cases of SA-BSI hospitalized for 7 days or longer. The median-Charlson-index was 6 (IQR 3-8). Most of the SA-BSI were secondary (85.9%) and the acquisition was nosocomial or health-care-related in 74.7%.

The median in-hospital stay was 24 days (IQR 14-39) and 18 patients were admitted in the Intensive Care Unit. The frequency of methicillin-resistant S. aureus was 25.3%. As for the outcome, 15 patients died within 30 days and 84 patients survived.

Attending the QIs, follow-up blood cultures were done in 77.8% of the cases, echocardiography in 72.7% and catheter removal in 94.4% of the cases with catheter-related bacteremia.

Overall, the median of the QCS was 8 (IQR 4-10). There was a statistically difference in the QCS in the survivors (median 9, IQR 6-11) vs non-survivors (median 3, IQR 2-7), p 0.01. In the analysis of subgroups of uncomplicated and complicated SA-BSI, there were also a significant difference in the QCS (uncomplicated SA-BSI: survivors median QCS 8 vs non-survivors median QCS -2, p < 0.01. Complicated SA-BSI: survivors median QCS 10 vs non-survivors median QCS 6, p < 0.01).

Conclusions: In our institution a QCS for SA-BSI seems simple to obtain and has prognostic implications.

Low Interferon gamma release assay conversion rate in healthcare workers after exposure to laryngeal tuberculosis

Kerstin Wissel*, Eva Lemmenmeier¹, Bernhard Mani², Matthias Schlegel¹

¹Cantonal hospital St. Gallen, Division of Infectious Diseases, St. Gallen, Switzerland, ²Zentrum für Labormedizin, St. Gallen, Switzerland

Background: High infectiousness of laryngeal tuberculosis is suspected in older studies, but newer data is missing. Screening for latent tuberculosis and offering preventive treatment is recommended for healthcare workers (HCW) in the setting of exposure to tuberculosis. The risk of infection with TB is supposed to depend on exogenous factors like time of exposure, but no evidence exist about relevant exposure time.

Materials/methods: In our 780-bed hospital we identified HCW exposed to a patient with smear positive laryngeal TB and offered an Interferon Gamma Release Assay (IGRA) at time of exposure and 2 months thereafter. We used QuantiFERON® TB Gold plus by Qiagen, Hilden, Germany, considered positive with a TB1 or TB2 > 0.35 IU/ml. Baseline samples were only analysed if the 2-month IGRA was positive.

Results: We screened 63 of 70 (90%) exposed HCW. The majority had a short exposure time: 51.4% (n=36) < 1 hour, 27.1% (n=19) 1-2 hours, 21% (n=5) 2-4 hours, 5.7% (n=4) 4-8 hours and 4.3% (n=3) > 8 hours. No information was provided by 4.3% (n=3). At 2-months after exposure 1/63 (1.6%) HCW had a positive IGRA (TB1 1.48 IU/ml, TB2 1.17 IU/ml). Conversion was confirmed by the analysis of the IGRA performed initially after exposure (TB1 0.35 IU/ml and TB2 0.11 IU/ml). This HCW was a room service staff with an exposition time of 1-2 hours without previous TB exposure. Treatment for latent TB was offered and started with rifampicin. Two immunocompromised HCW had a negative IGRA > 8 weeks after exposure.

Conclusions: In our contact tracing investigation of 63 exposed HCW to a case of smear-positive laryngeal tuberculosis we observed only 1 IGRA conversion in a HCW with short exposition time.

The low IGRA conversation rate of 1.6% challenges the notion of high infectiousness of laryngeal TB. To evaluate high-priority contacts with the longest duration of exposure might not be the best way to capture new infected persons. The low conversation rate questions the cost-benefit ratio of an expanded contact tracing in low incidence countries.

Abstract 4768

Retrospective analysis of Bordetella pertussis isolates collected by the National Reference Centre for Whooping Cough in France since 1995: focus on vaccine antigen-deficient isolates

Valerie Bouchez1,2, Sophie Guillot1,2, Annie Landier1,2, Nathalie Armatys1,2, Julie Toubiana1,2, Sylvain Brisse*1,2

1Institut Pasteur, Paris, France, 2National Reference Center for Whooping Cough and other Bordetella infections, Institut Pasteur, Paris, France

Background: Whooping cough is a vaccine preventable disease due to infection by Bordetella pertussis. Despite vaccination, B. pertussis (Bp) is still circulating. Acellular vaccines targeting 2 to 5 antigens, i.e., pertussis toxin (PT), filamentous hemagglutinin (FHA), pertactin (PRN) and fimbrial proteins (FIM2-FIM3) have fully replaced whole cell vaccines since 2006 in France. Antigen-deficient, in particular PRN-deficient, Bp isolates have been previously described. Surveillance of the production of the vaccine antigens by Bp isolates, and of the emergence of vaccine-escape sublineages, is essential regarding vaccine efficacy.

Materials/methods: The French surveillance of whooping cough is mainly based on a sentinel hospital-based voluntary surveillance network (called RENACOQ and coordinated by Santé Public France) covering about 30% of hospitalized pertussis pediatric cases. Part of the French national reference center (NRC) collection was retrospectively analyzed for vaccine antigen production using microbiological (Western blot or Serotyping) and genomic approaches.

Results: Among the French NRC collection, 1438 Bp isolates (1995 - 2018) were screened for PT, FHA and PRN production. Four (0.28%) PT-deficient, one (0.07%) PT/PRN-deficient, 4 (0.28%) FHA-deficient and 2 (0.14%) FHA/PRN-deficient Bp isolates were found. Some were collected before the introduction of acellular vaccination in France. Genomic events explaining loss of PT, FHA production were shown to be due to insertions, deletions or point mutations. Regarding PRN-deficient Bp isolates, their proportion has been increasing significantly, representing about half of Bp collected since 2015. Different genomic events lead to loss of PRN-production, two of which were predominant: an IS481 insertion within the prn gene, and a large inversion within the promoter region of the prn gene.

Bp isolates are usually producing either FIM2 or FIM3 fimbriae proteins. A subset of 1058 Bp isolates (2006 – 2018) were serotyped for both fimbriae proteins. Most isolates were producing FIM3, however, an increase of isolates producing FIM2 in the 4 last years has been noticed. Five (0.47%) isolates producing both FIM2 and FIM3, and only 10 isolates (0.94%) producing neither FIM2 nor FIM3 were observed.

Conclusions: These results show that except for PRN, vaccine antigens are still produced by the majority of circulating Bp isolates in France.

Molecular detection of the \textit{mcr-1} mobile colistin resistance gene in healthy humans and a dog with skin infection from Portugal

Juliana Menezes*1, Adriana Belas1, Inês Cunha E Silva1, Maria Constança Pomba1

1University of Lisbon, Faculty of Veterinary Medicine, Lisbon, Portugal

Background: Our aim was to investigate the occurrence colistin plasmid mediated resistance in \textit{Escherichia coli} recovered from fecal samples of humans and companion animals (CAs) in Portugal.

Materials/methods: Between February 2018 and October 2019, fecal samples were collected from CAs and their human household members. Informed consent was obtained. Samples were plated after prior pre-enrichment in peptone water onto Super-Polymyxin medium. For each fecal sample, colonies with \textit{E. coli} phenotypic aspect were isolate and identification was confirmed by PCR. Minimal inhibitory concentration (MIC) for colistin was performed by broth microdilution (Sensititre \textsuperscript{TM} FRCOL, Thermo Fisher Scientific, Wesel, Germany). All isolates were screened by PCR for the presence of five colistin resistance genes (\textit{mcr-1} to \textit{mcr-5}) and Sanger sequencing was performed.

Results: Seventy households constituted of healthy humans (\textit{N}=106) living with healthy CAs (\textit{n}=49) and CAs with skin and soft tissue (SSTI) and urinary tract (UTI) infections (\textit{N}=19, \textit{N}=16, respectively) were enrolled. Of these, 95 fecal samples (89.6\%) from humans, 45 from dogs (healthy-31, SSTIs-19 and UTI-3) and 21 from cats (healthy-18 and UTI-3), were positive for \textit{E. coli} in the SuperPolymyxin medium. Broth microdilution confirmed colistin resistance in 3.1\% (5/161) isolates (three from humans and two from dogs with skin infection), with MICs between 2-8 mg/L. Molecular analysis revealed that three of the \textit{E. coli} isolates carried the \textit{mcr-1} gene, two from two healthy humans and one from a dog with skin infection, all from different households.

Conclusions: To our best knowledge, this is the first report of the presence of the \textit{mcr-1} gene from a dog and in healthy humans in Portugal. The remaining isolates showing resistant phenotype to colistin lacking the studied resistance genes will be screened for other \textit{mcr}-gene variants (\textit{mcr-6} to \textit{mcr-9}). Further studies are needed to determine the full epidemiology of colistin resistance genes in humans and companion animals.

Lemongrass oil: a promising acaricidal and ovicidal agent against scabies?
Li Meilin1, Liu Buming2, Charlotte Bernigaud3, Jacques Guillot4, Fang Fang1

1Guangxi University, College of Animal Science and Technology, Parasitology Department, Nanning, China, 2Guangxi University, Guangxi Institute of Traditional Medical and Pharmaceutical sciences, Nanning, China, 3Université Paris Est Créteil, Dermatology Department, AP-HP, Hôpital Henri Mondor, Créteil, France, 4Université Paris Est Créteil, Ecole nationale vétérinaire d’Alfort, Maisons-Alfort, France

Background: Scabies is a frequent cutaneous infection caused by the mite Sarcoptes scabiei in a large number of mammals including humans. Current therapeutic options are not optimal and there is an unmet need for new acaricide products. Essential oils may represent an alternative strategy for controlling scabies. Lemongrass oil is reported to possess a large panel of pharmacological properties. The aim of the present study was to assess the potential efficacy of lemongrass oil against Sarcoptes scabiei.

Materials/methods: The chemical components of lemongrass oil were identified by GC-MS analysis. We evaluated the efficacy of lemongrass oil against S. scabiei mites and eggs collected from naturally infected rabbits in China. Lemongrass oil was diluted with paraffin to get concentrations of 10%, 5%, 1%, 0.5% and 0.1%. Mite mortality was monitored and evaluated under a stereomicroscope every 10 min until 1 h, and then after 3h, 6h, 12h, and 24h of exposure to treatment. The hatchability of eggs was determined under a stereomicroscope 5 days after exposure to lemongrass oil.

Results: GC-MS analysis confirmed that the main component was citral. Lemongrass oil at concentrations of 10% and 5% killed all Sarcoptes mites within 10 and 25 min, respectively. The median lethal concentration (LC50) value was 1.37%, 1.08%, 0.91%, 0.64%, and 0.48% at 1, 3, 6, 12, and 24h, respectively. Lemongrass oil at all concentrations was able to significantly decrease the hatching rate of Sarcoptes eggs (Figure 1).

Conclusions: The results demonstrated that lemongrass oil should be considered as a promising acaricidal and ovicidal agent for scabies control.

![Figure 1. Hatching rates of Sarcoptes eggs exposed to different concentrations of lemongrass oil under laboratory conditions (35°C and ≥80% relative humidity).](image-url)

Abstract 4771

**HIV-1 transmitted drug resistance is slowly rising in Estonia in 2017**

Arina Šablinskaja*1, Pauskar Merit1, Ene-Ly Jõgeda1, Heli Rajasaar1, Pilleriin Soodla1, Evely Kallas1, Taavi Päll1, Kristi Rüütel2, Irja Lutsar1, Kristi Huik1,3, Radko Avi1

1University of Tartu, Institute of Biomedicine and Translational Medicine, Tartu, Estonia, 2National Institute for Health Development, Tallinn, Estonia, 3 National Institutes of Health, Frederick, United States

**Background:** Transmitted drug resistance (TDR) prevalence in Europe has been stable around 10% for the last decade. Estonian TDR levels have been lower, however after rapid scale-up of antiretroviral therapy has occurred it started slowly increasing from 4.5% in 2010 to 6.7% in 2013. We aimed to determine the level of TDR and HIV-1 subtypes in Estonia in 2017.

**Materials/methods:** Study included all available samples of newly diagnosed HIV-1 individuals (216 samples out of 219) from January 1 until December 31, 2017. Patients’ demographic and clinical data were obtained from the Estonian Health Board and databases of clinical laboratories. HIV RNA was sequenced in protease and reverse transcriptase region, followed by the determination of transmitted drug resistance mutations (DRMs) and HIV subtypes using Stanford HIV Drug Resistance Database Calibrated Population Resistance and REGA HIV-1 Subtyping Tool, respectively.

**Results:** The majority of newly diagnosed individuals were men (146/219; 67%) with median age of 36 years. The most common transmission route was heterosexual contact (88/129; 68.2%). The median HIV-1 viral load was 16,051 copies/ml (IQR 4775-157,605) and median CD4 cell count 364 (IQR 204-544) cell/µl.

The overall level of TDR was 7.6% (11/144; 95% CI 4.0-13.5). The most common DRM was the non-nucleoside reverse transcriptase inhibitor (NNRTI) mutation K103N, found in seven cases (7/11; 63.6%). NNRTI mutations G190A and Y188L, as well as nucleoside reverse transcriptase inhibitors mutations M184V and M41L were each found in single cases, whereas only one virus possessed two DRMs (K103N and G190A). No protease inhibitor mutations were found.

The majority of the viruses belonged to the CRF06_cpx subtype (93/144; 64.6%), followed by the subtype A1 (15/144; 10%), subtype B (9/144; 6%), subtype G (6/144; 4%) and unclassified URFs (12/144; 8.3%).

**Conclusions:** TDR is rising in Estonian HIV-1 infected population, which indicates that continuous monitoring is necessary in the future. Low genetic barrier NNRTIs should not be considered as a treatment option. HIV-1 subtype distribution has remained stable, indicating no impact of immigration to developing TDR in Estonia.

Current evidence on dose reduction of antibiotics in patients with impaired renal function: a systematic review

Suzanne De Vroom*1, Frederike Van Daalen1, Saskia Zieck2, Ron Mathôt2, Reinier Van Hest2, Suzanne E. Geerlings1

1Academic Medical Centre, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam Infection and Immunity (AI&II), Amsterdam, Netherlands, 2Academic Medical Centre, Department of Hospital Pharmacy, Division of Clinical Pharmacology, Amsterdam, Netherlands

Background: Inconsistency exists between many guidelines in the recommended dose reduction of antibiotics in patients with impaired renal function. We aimed to define if dose reductions are evidence-based and adequate by systematically searching the literature for clinical studies investigating drug exposure or pharmacokinetic-pharmacodynamic (PK-PD) target attainment after dose reduction of antibiotics in patients with impaired renal function.

Materials/methods: We performed a systematic review searching MEDLINE and Embase from 1946, respectively 1947 until August 2019. We included studies that reported drug exposure (maximum concentration [Cmax], minimum concentration [Cmin], area under the concentration-time curve [AUC]) and/or PK-PD target attainment after dose reduction of antibiotics in patients with impaired renal function. The reduced dose was adequate if the relevant measures of drug exposure and/or PK-PD target were comparable (within a range of 80% - 125%) with that in patients with adequate renal function receiving regular doses. Risk of bias was assessed and this study was prospectively registered in PROSPERO (CRD42019120073).

Results: We included 27 studies, mainly on beta-lactams (12/27) and fluoroquinolones (9/27) and the majority included patients with clinical infections (16/27). Quality of most studies was fair (19/27). Only for meropenem and cefepime good quality evidence from multiple studies was available. For both meropenem and cefepime drug exposure was higher in patients with impaired renal function receiving reduced doses compared to patients with adequate renal function receiving regular doses, so doses are not reduced enough. For all other antibiotics where a dose reduction is recommended good quality evidence of more than one study is lacking. Additionally, remarkable heterogeneity in the definition of renal impairment and the applied dose reductions for individual antibiotics was observed between studies.

Conclusions: Sound evidence on whether dose reductions of antibiotics in patients with impaired renal function lead to comparable drug exposure as in patients with adequate renal function receiving regular doses, is lacking, with exception of meropenem and cefepime. There is need for a clear definition of renal impairment, below which the dose per antibiotic should be reduced and need for prospective validation of the currently most general recommended dose reduction of antibiotics.

Abstract 4781

**Prospective surveillance of invasive group A streptococcal disease in the Netherlands**

Lidewij Rumke*, Stefan Vestjens1, Arie Van Der Ende2, Brechje De Gier3, Nina Van Sorge1, Bart Vlaminckx4

1UMC Utrecht, Utrecht, Netherlands; 2Academic Medical Centre, Amsterdam, Netherlands; 3National Institute for Public Health and Environment, Bilthoven, Netherlands; 4St. Antonius Hospital, Nieuwegein, Netherlands

**Background:** A re-emergence of group A Streptococcal (GAS) infections has been reported by countries across the world. In the Netherlands increasing frequencies of GAS-related postpartum fever and fatal infections among infants were reported in 2018-2019. Recently Lynskey et al. (Lancet Infect Dis 2019) described the emergence of a novel emm1 lineage in the UK, which likely caused increased disease burden both for non-invasive and invasive GAS (iGAS) disease. To improve our understanding of iGAS epidemiology in the Netherlands, a national surveillance study was initiated.

**Materials/methods:** As of January 2019, Dutch GAS isolates from normally sterile body sites and isolates from non-sterile sites from patients with a clinical picture of iGAS disease have been collected. Isolates and patient’s demographic characteristics were submitted by nine participating laboratories covering approximately 25% of the country. All isolates were emm typed.

**Results:** In 2019 up to 26/11/2019, 136 cases of iGAS were identified. The median age was 41 years (range 0-99). Gender was equally distributed, except in age group 15-45 years (78% female). Most isolates were obtained from blood (46%) and the genital tract (18%), others from the respiratory tract (5%), not further specified puncture fluid (6%), tissue (6%) or abscesses (4%), joint fluid (4%), wounds (3%) and cerebrospinal fluid (2%). Twenty-one different emm types were detected. Overall, the most prevalent emm types were emm1 (30%), emm89 (10%), emm77 (9%), emm6 (8%) and emm22 (8%). The emm type distribution per culture specimen category is shown in Figure 1. Emm1 was seen significantly more in blood than genital isolates (p=0.02). Emm89 was the most dominant emm-type among genital isolates.

**Conclusions:** Dutch iGAS surveillance data shows that emm1 was the most prevalent emm type among patients with iGAS in 2019 in the Netherlands. Emm89 was the most prevalent emm type among isolates from the genital tract, reflecting a predominance among puerperal iGAS infections. Emm3 was not detected in this surveillance, despite its predominance in Dutch iGAS surveillance data from 1994-2003. In the near future, our results will be supplemented with additional genotyping and clinical data to define high-risk populations, which might impact prophylactic antibiotic treatment guidelines.

**Figure 1. Distribution of emm types in iGAS isolated from blood, genital tract and other sites**

[Graph showing distribution of emm types]

iGAS = invasive group A streptococcal; *Other culture specimens: respiratory tract, not further specified puncture fluid, tissue, abscesses, joint fluid, wounds, cerebrospinal fluid; **Remaining emm types: 4, 11, 12, 20, 29, 76, 66, 82, 87, 84, 104, 118, 145, 168, 170 and STG 682

Active follow-up of patients colonised with highly-resistant microorganisms to discontinue isolation measures

Cynthia Paola Haanappel1, Anne Voor In’t Holt1, Lonneke Bode1, Inge De Goeij1, Margreet C. Vos1

1Erasmus University Medical Centre, Rotterdam, Netherlands

Background: To prevent nosocomial transmission of highly resistant microorganisms (HRMO), preventive measures must be taken when patients colonized with HRMO are hospitalized. Contact isolation measures however, are costly and labour-intensive. Since HRMO carriage can be temporary, isolation measures are discontinued once a patient is proven to be HRMO free. In our hospital, up until 2019, follow-up cultures for HRMO carriage were not routinely taken, possibly resulting in unnecessary isolation measures. Therefore, active patient follow-up was started in 2019, aiming to quickly declare patients HRMO free to reduce costs and workload due to isolation measures.

Materials/methods: This before-and-after design study was conducted in the Erasmus University Medical Centre, Rotterdam, The Netherlands. According to the local protocol, patients were declared HRMO free after two consecutive negative rectum and throat cultures. Patients with an HRMO identified between October 2013 until December 2018 were cultured only upon request of their treating physician. Patients colonized with HRMO from January 2019 onwards were actively contacted for follow-up cultures. For evaluation of the economic impact of this active patient follow-up regimen, the extra direct costs of hospitalization days in isolation were calculated, as well as the number of hospitalization days in isolation in both the active and passive follow-up periods.

Results: From October 2013 until November 2019, a total of 3522 HRMO patients were identified. 2571 patients were included with passive follow-up and 481 with active follow-up. 219 out of 481 patients identified in 2019 were eligible for culturing. Regarding active follow-up, in total, patients were hospitalized in isolation for an average 14.3 days (median=3.0) compared to 22.5 days (median=9.0) days for patients included in the passive follow-up (P>0.001). An analysis with fixed follow-up periods will follow.

Conclusions: Patients who received active follow-up had significantly less isolation days during hospitalization. However, results are based upon a limited selection of the patients identified in 2019. To get a better estimation of the impact of active follow-up a longer follow-up time and a larger number of inclusion is needed. Therefore, this study will continue to collect additional results.

Abstract 4793

Transforming a multiplex laboratory developed real-time PCR for herpes simplex virus type 1 and 2 & varicella zoster virus into a sample-to-answer, cassette-based format

Marije Dierckx¹, Reinoud Cartuyvels¹, Marijke Raymaekers*¹

¹Jessa Ziekenhuis, campus Salvator, Klinisch Labo, Laboratorium voor Moleculaire Diagnostiek, Hasselt, Belgium

Background: Viral encephalitis is a devastating infection of the central nervous system. Early diagnosis of Herpes simplex virus (HSV) or Varicella zoster virus (VZV) encephalitis allows prompt administration of acyclovir which reduces neurological damage and mortality significantly. The ARIES system (Luminex Corporation) is a fully automated sample-to-answer molecular diagnostic instrument on which CE-IVD assays and Laboratory Developed Tests (LDT) can be performed. In this study, we evaluated the LDT capabilities of ARIES by converting an existing multiplex real-time PCR for HSV 1/2 & VZV (Taqman) with extraction on Qiasymphony SP/AS (QS SP/AS) (Qiagen) and amplification on Rotorgene Q (RGQ) (Qiagen) into a cassette-based ARIES assay. The performance of these two assays was compared.

Materials/methods: Carrier RNA, proteinase K and an internal extraction and amplification control (IC) was added directly to the sample. The primers and probes were added in the same concentration as for RGQ to a tube containing lyophilized ARIES Exo+ Ready Mix (Luminex Corporation). This tube was clicked onto an ARIES extraction cassette and the sample was added to the cassette. Subsequently, the cassette was processed onto the Aries system, following completion in 2 hours. Total hands on time was 5 minutes.

Sensitivity, reproducibility and accuracy was determined and a retrospective analysis of RGQ positive and negative patient samples was performed. A Ct-value for inhibition cut-off was also established.

Results: The multiplex real-time PCR for HSV 1/2 & VZV assay on Aries showed a RGQ comparable sensitivity of 100 copies/ml, a good reproducibility (ΔCt < 2.5) and an accuracy of 100%. There was also an excellent concordance for all patient samples between Aries and RGQ. Inhibition was seen when the Ct-value for IC was > 33.

Conclusions: This study demonstrates the easy transition from a QS SP/AS followed by RGQ multiplex real-time PCR for HSV 1/2 & VZV assay to a sample-to-answer format on ARIES with an excellent performance on the ARIES. Only a minimal optimization for sample pretreatment was needed for a successful transfer to ARIES. The ARIES offers a valuable addition to the routine laboratory.

Abstract 4795

**Antimicrobial resistance in Italy: data from the National Surveillance System AR-ISS over a 7-year period, 2012-2018**

Monica Monaco*, Stefania Bellino, Simone Iacchini, Maria Del Grosso, Romina Camilli, Giulia Errico, Fabio D’ambrosio, Fortunato D’ancona, Stefania Iannazzo, Patrizio Pezzotti, Annalisa Pantosti

1Istituto Superiore di Sanità, Department of Infectious Diseases, Rome, Italy, 2Ministry of Health, Directorate General for Health Promotion, Rome, Italy

**Abstract third-party references:** Italian Ministry of Health

**Background:** Data from routinely collected samples from invasive isolates of eight pathogenic species were collected by the Italian antibiotic-resistance surveillance network (AR-ISS), coordinated by the Istituto Superiore di Sanità. The aim of the study was to analyse the temporal trend from 2012 to 2018 of antimicrobial resistance (AMR) for selected classes of antibiotics as well as multi-drug resistance of Gram-negative bacteria and the most important drugs/pathogen combinations.

**Materials/methods:** The percentages of AMR with 95% confidence intervals were calculated overall and by Italian Regions. Multi-level logistic regression models (clustered by hospital laboratory) were applied to evaluate the association between each of the four considered drugs/pathogen combinations (MRSA, methicillin-resistant *Staphylococcus aureus*, VRE- *faecium*, vancomycin-resistant *Enterococcus faecium*, CREC, third generation cephalosporins-resistant *Escherichia coli*, CRKP, carbapenem-resistant *Klebsiella pneumonia*) and patients’ characteristics (sex, age, hospital ward, geographical area), taking into account also the laboratory effect by calculating the percentage of variation attributable to differences among laboratories (intra-class correlation).

**Results:** A total of 128,510 isolates from blood and cerebro-spinal fluid were collected during the study period. The percentage of MRSA remained quite stable (around 34%) over the whole period, whereas a significant decline was observed in the last two years for CRKP (from 33.8% in 2016 to 29.5% and 26.8% in 2017 and 2018 respectively); conversely a sharp increase was observed for VRE-*faecium* (from 6.3% in 2012 to 18.9% in 2018). A higher risk of resistance was associated with male sex (except for VRE-*faecium*), older age (18-64 and ≥65 versus 0-17 years old), intensive care and surgery (the latter only for MRSA and CRKP) as compared to medicine units. Moreover, AMR interregional variation was observed, and only for CRKP higher values of resistance were found in southern Italy compared to the other regions.

**Conclusions:** Although in the last years AMR showed a decreasing trend in Italy, likely due to more coordinated activities in accordance to the national action plan, higher resistance rates continue to be observed as compared to the EU mean values. Appropriate antimicrobial use, infection prevention and control strategies are essential for effective interventions aiming to prevent selection and transmission of bacteria resistant to CIAs.

The relationship between clinical outcomes and empirical antibiotic therapy in patients with community-onset Gram-negative bloodstream infection: a cohort study from a large teaching hospital

Anna Aryee*1, Patrick Rockenschaub1, Martin Gill2, Andrew Hayward3, Laura Shallcross1

1University College London, Institute of Health Informatics, London, United Kingdom, 2University Hospital Birmingham, University Hospital Birmingham, Birmingham, United Kingdom, 3University College London, Institute of Epidemiology and Health Care, London, United Kingdom

Abstract third-party references: Supported by NIHR, Supported by The Wellcome Trust

Background: The incidence of Gram-negative bacteraemias (GNB) that are resistant to first line antibiotics is increasing. The widespread use of broad-spectrum antibiotics for suspected GNB, to avoid a delay in initiating effective therapy in patients with antibiotic-resistant GNB, in turn promotes the emergence of antibiotic-resistant strains. We set out to investigate the impact of discordant empirical antibiotic therapy on clinical outcomes in patients with GNB, to inform prescribing guidelines.

Materials/methods: An observational cohort study of patients admitted to Queen Elizabeth Hospital Birmingham between 01/09/2011-01/01/2018 due to community-onset Escherichia coli bacteraemia (ECB), Klebsiella pneumoniae bacteraemia (KPB) and Pseudomonas aeruginosa bacteraemia (PsAB). We estimated the association between concordant versus discordant empirical antibiotic therapy on the odds of in-hospital death and ICU admission, adjusting for clinical and demographic factors.

Results: 1380 patients were included in the study, of whom 1103 (79.9%) had ECB, 189 (13.7%) had KPB and 88 (6.4%) had PsAB. Discordant antibiotic therapy was not associated with increased odds of in-hospital death or ICU admission for patients with ECB. For KPB, there was an increased odds of in-hospital death with discordant treatment (adjusted OR 4.78, 95% CI 1.25-18.33). In patients with ECB, a non-urinary source and increased disease severity (standardised early warning scoring system (SEWS) score of ≥4 as compared to 0-3) were respectively associated with a 3- (adjusted OR 3.19, 95% CI 1.72-5.92) and 8-fold (adjusted OR 8.05, 95% CI 4.25-15.24) increased odds of in-hospital death.

Conclusions: Patients with non-urinary source ECB and higher severity scores were more likely to experience adverse outcomes including death and ICU admission. This emphasises the need for prompt broad-spectrum antibiotics in patients with signs of a non-urinary source or clinical markers of severe illness, in support of campaigns such as Surviving Sepsis. These findings also support the use of narrow-spectrum empirical antibiotics in low risk patients with ECB (almost 80% of our cohort) of urinary source. By contrast, in patients with KPB, discordant empirical therapy was associated with adverse outcomes. This highlights the need for tools to guide empirical prescribing decisions, which consider the likely source of infection, pathogen and disease severity.

Abstract 4800

Pharmacokinetic evaluation of micafungin prophylaxis for invasive mould disease in childhood acute lymphoblastic leukemia: part of the OPTIMA study

Didi Bury*1,2; Rob Ter Heine2; Wim Tissing1;3, Eline Muilwijk1, Tom Wolfs4, Roger Brüggemann2

1Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, 2Radboud University Medical Center, Nijmegen, Netherlands, 3University Medical Center Groningen, Groningen, Netherlands, 4Wilhelmina Children’s Hospital [WKZ], Utrecht, Netherlands

Abstract third-party references: Princess Máxima Center for pediatric oncology, Radboud university medical center

Background: The Princess Máxima Center for pediatric oncology recently introduced a new biweekly prophylactic regimen of micafungin for invasive mould disease. Extended dose intervals of micafungin could overcome the need of frequent hospital visits. As part of this new strategy, we aimed to determine the pharmacokinetics of micafungin and to simulate various dose regimens that could be deployed as a mould active prophylactic regimen.

Materials/methods: Micafungin was given biweekly at 9 mg/kg as a two hour infusion during the first five weeks of the induction treatment in pediatric patients with newly diagnosed ALL. A five-point sample curve was obtained (t=0, 2.5, 4, 5 and 24h). The PK of micafungin was analysed using non-linear mixed effects modeling, with clearance (Cl) and volume of distribution (Vd) allometrically scaled to total body weight. Monte Carlo simulations with four different dosage regimens were performed: 5 mg/kg, 7 mg/kg and 9 mg/kg with a maximum dose of 300 mg and flat dose per weight band (0-10kg received 50mg, 10-20kg received 100mg, 20-40kg received 150 mg and >40kg received 300 mg). Simulated pediatric exposure was compared to exposure in adults after 100mg daily.

Results: 62 patients were included with a total of 270 observations. Median age and weight with range were 4(1-17) years and 19.3(8.6-177.2) kg. A two-compartment model with intravenous administration and linear elimination best fitted the data. Typical parameter values with relative standard error (RSE%) were for clearance (Cl) 0.668(3%) L/h, central Vd (V1) 9.87(15%) L, peripheral Vd (V2) 7.15(17%) L and intercompartmental Cl (Q) 2.65(35%) L/h. Simulated micafungin exposure (i.e. median area under the curve (AUC)) with interquartile range (IQR)) for the 5 mg/kg, 7 mg/kg, 9 mg/kg and flat dosing regimens were respectively 783(245) mg·h/L, 1043(301) mg·h/L, 1251(380) mg·h/L and 951(323) mg·h/L. All simulated regimens exceeded the micafungin exposure in adults of 690(244) mg·h/L.

Conclusions: Our 9mg/kg biweekly dose suggests an above average micafungin exposure compared to adults receiving 100mg daily. Our clinical study has currently enrolled 100 patients and will provide the evidence for efficacy and safety of this 9 mg/kg regimen. A flat dose per weight band may be a suitable alternate.

Abstract 4801

Prolonged viral shedding in bronchial aspirate fluids in a patient with measles-related severe pneumonia

Licia Bordi1, Mario Antonini1, Concetta Castilletti1, Emanuele Nicastri1, Francesca Colavita1, Alessandra D’Abramo*1, Laura Scorzolini1, Micaela Maritti1, Maria Rosaria Capobianchi1, Eleonora Lalle2

1Lazzaro Spallanzani Hospital, Rome, Italy, 2Lazzaro Spallanzani Hospital, Roma, Italy

Background: Measles, a vaccine-preventable disease, is currently responsible for worldwide outbreaks mainly due to the lack of adequate immunization. Pneumonia is the most common, even life-threatening, complication of measles. We report a case of measles-related severe pneumonia in a 56-year-old man with history of schizophrenia, hypertension, dyslipidemia, and chronic obstructive bronchopneumopathy.

Materials/methods: The patient was admitted at the Intensive Care Unit of INMI and mechanically ventilated on April 2019, following a morbilliform rash and a severe respiratory insufficiency, with 15 APACHE II [Acute Physiology and Chronic Health Disease Classification System II] score and 4 SOFA [Sequential Organ Failure Assessment] score. Measles diagnosis, based on positive measles-specific serological tests, was confirmed by molecular test on urine.

Results: Due to the clinical progression to Acute Respiratory Distress Syndrome (ARDS), longitudinal bronchial aspirates (BAS) were performed, to assess for bacterial, viral or fungal infections in lung. No detection of respiratory pathogens by PCR or culture was demonstrated, apart from a positive MV PCR in the BAS at day 13 from admission. All previously collected BAS samples were retrospectively studied for MV PCR and all resulted positive, providing evidence of a measles-related pneumonia. A prolonged persistence of MV in BAS (27 days) was observed, peaking at day 8 and 17 following admission, corresponding to worsening of the respiratory function and febrile episodes, while MV viremia was undetectable. Since MV was still detectable in BAS when the patient was extubated and transferred to the acute care setting (day 28), measles PCR monitoring was performed on longitudinally collected pharyngeal swabs. The patient was maintained in respiratory isolation until day 33, when both clinical improvement and MV clearance in pharyngeal swab were observed. At discharge (day 47), the patient was still MV PCR positive in the urine.

Conclusions: The presence of MV RNA was observed in specimens of the lower respiratory tract, even after viral clearance from plasma, suggesting a local replication. Prolonged viral shedding in respiratory samples is to be considered in patients with measles-associated-ARDS. Concerns on the prolonged duration of respiratory isolation measures deserves careful consideration in respect of infection transmission risk in the hospital setting.

Abstract 4802

**Carbapenemase-producing organisms in high-risk units of a district general hospital in London**

Sophia De Saram*1, Nyarayi Mukombe1, Joella La Lucas1, Roxanne Forbes1, Mariyam Mirfenderesky1, Nehal Draz1

1North Middlesex University Hospital NHS Trust, London, United Kingdom

**Background:** The epidemiology of carbapenemase-producing organisms in district general hospitals in London has not yet been well documented. Our district general hospital serves a diverse, mobile population in North London. Here we describe the epidemiology of carbapenemase-producing organisms (CPO) in patients admitted to high-risk wards.

**Materials/methods:** A retrospective analysis was carried out of all resistant organism screens performed over a 12 month period on the Critical Care Unit (CCU), Acute Stroke Unit (ASU), Neonatal Unit (NNU) and Oncology and Haematology ward (Onc/Haem). Admission and weekly screening of patients by rectal swab is carried out on these wards.

**Results:** Over the 12 month period 5,238 resistant organism screens were performed on 2,064 patients. 71 carbapenemase-producing organisms were isolated from 60 patients. 2.9% of inpatients on the high-risk units were colonised with a carbapenemase-producing organism. Prevalence was 7.0% on ASU, 2.0% on CCU, 1.0% on Onc/Haem and 0.5% on the NNU. The most common organism isolated was Enterobacter cloacae in 39 patients. The most common enzyme identified was NDM in 45 patients, whilst OXA-48 was found in 14 patients, VIM in 1 and OXA-23 producing Acinetobacter in 2 patients.

**Conclusions:** Carbapenemase-producing organisms were found in patients throughout the high-risk units of our district general hospital. Our findings highlight the importance of regular screening on these units, particularly given the vulnerable nature of these cohorts and the extent to which they move across the regional hospital network as part of specialist service referral pathways. Documenting patients’ CPO-carrier status is crucial for implementing appropriate infection prevention and control measures as well as guiding antimicrobial choice.

Abstract 4805

Molecular detection of *Mycoplasma amphoriforme* and *Ureaplasma* species from patient samples previously investigated for *Mycoplasma pneumoniae* infection in England and Wales between 2016 – 2017

Safi Rehman¹, Sarah Maddocks¹, Baharak Afshar², Jessica Day², Victoria Chalker², Michael Beeton*¹

¹Cardiff Metropolitan University, Cardiff, United Kingdom, ²Public Health England, London, United Kingdom

**Background:** *Mycoplasma amphoriforme* is associated with respiratory tract infections among patients with primary antibody deficiencies with limited prevalence data among immunocompetent individuals. *Ureaplasmas* have been associated with hyperammonemia among lung transplant patients, but little is known regarding their presence within respiratory samples among patients which are immunocompetent.

**Materials/methods:** Residual DNA samples (161) submitted for *Mycoplasma pneumoniae* testing to Public Health England (PHE), from September 2016 to December 2017 were screened by an in-house qPCR assay for the presence of *M. amphoriforme* and conventional PCR for *Ureaplasma* spp and *Mycoplasma fermentans*. *Ureaplasma* species were detected using a differential in-house PCR assay which amplified a variable region resulting in 448 bp amplicon for *Ureaplasma urealyticum* and 403 bp for *Ureaplasma parvum*. The presence or absence of macrolide resistance determining mutations within domain V of the 23s rRNA was determined by PCR and sequencing of *M. amphoriforme* positive samples.

**Results:** A total of ten samples were positive for *M. amphoriforme* (6.2%), five samples were positive for *U. parvum* (3.1%) and no samples were found to contain *M. fermentans* DNA (0%). Three out of the ten *M. amphoriforme* positive samples were previously identified as positive for *M. pneumoniae* suggesting co-infection. All ten *M. amphoriforme* were genotypically susceptible to macrolide antibiotics (100%). Of the samples which were positive for *M. amphoriforme* 9/10 were from male patients, whereas for the *U. parvum* positive samples 3/5 were male. No *M. amphoriforme* detections were seen during the summer months.

**Conclusions:** These data suggest that *M. amphoriforme* can be found among clinical samples in patients suspected to have *M. pneumoniae* and it may represent an emerging respiratory pathogen. *U. parvum* can be found in the lungs of patients with suspected lower respiratory tract infections and maybe a reservoir and source of donor-derived infection among lung transplant recipients. In both instances, further investigation of their prevalence is required.

**Presenter email address:** mbeeton@cardiffmet.ac.uk
A new high-resolution melting PCR assay for a rapid detection of linezolid-resistance-associated mutations in Mycobacterium avium complex

Rosario Musumeci1*, Luisa Molteni1, Ester Mazzola2, Stefania Torri2, Diana Fanti2, Alice Nava2, Marianna Martinelli2, Federica Perdoni2, Chiara Villa2, Perno Carlo Federico2, Clementina Cocuzza1

1University of Milano-Bicocca, Laboratory of Clinical Microbiology and Virology, Department of Medicine and Surgery, Monza, Italy, 2ASST Grande Ospedale Metropolitano Niguarda, Analisi Chimico-cliniche e Microbiologia, Milan, Italy, 3University of Milano-Bicocca, Laboratory of Applied Biology and Human Genetics, Department of Medicine and Surgery, Monza, Italy

Background: Mycobacterium avium complex (MAC) is a group of slowly growing non-tuberculous mycobacteria that is emerging as major infectious threat in developing countries. The most frequent are M. avium and M. intracellulare, for which the conventional treatment is a macrolide-based multidrug regimen. However, due to the increased macrolide-resistance, alternative treatments are needed.

Linezolid, the only FDA-approved oxazolidinone for mycobacterial diseases representing 2nd line treatment for M. tuberculosis, has been shown to have a good activity against Non-Tuberculous Mycobacteria (NTM) [Winthrop et al. 2015]. However, the long-term treatment, typical for mycobacterial infections, promotes the acquisition of linezolid-resistance due to mutations in rrl, rplC and rplD.

In this study we developed a High-Resolution Melting (HRM) PCR assay to detect linezolid-resistance-associated mutations in MAC.

Materials/methods: An HRM PCR assay was performed on 55 linezolid-resistant MAC clinical isolates (50 M. avium and 5 M. intracellulare) provided by ASST Grande Ospedale Metropolitano Niguarda (selected following American Thoracic Society Criteria) to detect linezolid-resistance-associated mutations in rrl, rplC and rplD genes.

The results were analysed using Precision Melt Analysis™ software (BioRad) obtaining different clusters based on mutations presence and then verified through Sanger sequencing.

Results: Preliminary results, based on 10 MAC (5 M. avium and 5 M. intracellulare), showed in 20% of isolates mutations in rplD gene: G443A (Arg148Lys) in M. intracellulare and A439G (Thr147Ala) in M. avium, respectively, already identified in a recent study [Kim et al 2018]. We have also found new mutations, never reported before (data not shown) and under confirmation.

Conclusions: In recent years, in the Milan macroarea, MAC clinical isolates have shown low resistance to first line drugs (1.2% for clarithromycin and 4.7% for intravenously-administered amikacin), but high level of resistance for second line drugs (40.2% for moxifloxacin and 91% for linezolid). Linezolid-resistance is higher in our strains compared to that described in other parts of the world.

The HRM PCR assay is a rapid screening method to discriminate wild type from mutated sequences thanks to creation of different clusters. This can be useful to detect new and known linezolid-resistance-associated mutations both before and during treatment to monitoring the resistance onset.

Intestinal colonisation by multidrug-resistant Enterobacteriaceae and infections in patients receiving an allogeneic haematopoietic stem cell transplantation: the ENTHERE-SCT Study [PI16/01415]

Claudia González Rico*1, Marta Fernández-Martínez2, M. Aranzazu Bermúdez-Rodríguez1, Irene Gracia-Ahufinger4, Inmaculada García-García3, Guillermo Maestro2, Concepción Farías Alvarez1, Carmen Martín Calvo4, Jose M. Aguado Garcia1, Lourdes Vázquez2, Luis Martínez-Martínez2, Mª Carmen Farías1

1Infectious Diseases Service, Marqués de Valdecilla University Hospital-IDIVAL, Santander, Spain, 2Microbiology Service, Marqués de Valdecilla University Hospital-IDIVAL, Santander, Spain, 3Haematology Service, Marqués de Valdecilla University Hospital, Santander, Spain, 4Unit of Microbiology, University Hospital Reina Sofia-MIBIC-University of Córdoba, Córdoba, Spain, 5Microbiology Service, University Hospital of Salamanca, Salamanca, Spain, 6Infectious Diseases Unit, University Hospital 12 de Octubre, Madrid, Spain, 7Division of Health Care Quality, Marqués de Valdecilla University Hospital-IDIVAL, Santander, Spain, 8Unit of Haematology, University Hospital Reina Sofia, Córdoba, Spain, 9Haematology Service, University Hospital of Salamanca, Salamanca, Spain

Background: Currently, it is being discussed whether intestinal colonisation by multidrug-resistant Enterobacteriaceae (MDRE) in patients receiving hematopoietic stem cell transplantation (Allo-SCT) is a risk factor for developing systemic infections. The aim of this study was to analyze the risk factors of intestinal colonisation by MDRE and the development of infections in patients with Allo-SCT.

Materials/methods: multicenter prospective cohort study conducted at four third level Spanish hospitals between June 2017 and March 2019. A rectal swab was collected before Allo-SCT and then, weekly until day 30 after transplantation, every two weeks until day 100 after transplantation and monthly until day 180 after the transplant. Clinical and microbiological data were collected during patient follow-up.

Results: Sixty four patients were included (28 from Hospital 1, 20 from Hospital 2, 10 from Hospital 3 and 6 from Hospital 4). Twenty four (37.5%) patients were colonized by MDRE at some point in the follow-up, 4 (6.3%) of them before Allo-SCT. Colonized and non-colonized patients had similar demographic factors [sex, age and underlying disease], and risk factors such as HCT-CI score and previous invasive procedures, hospital admission and infections (Table 1). One hundred and sixteen episodes of infection were recorded in 51 patients: 55 (47.4%) in 22 colonized patients and 61 (52.6%) in 29 non-colonized patients. The most frequent type of infection was bacteremia (50.0% in colonized patients and 32.5% in non-colonized patients), followed by respiratory infections, CMV infection and urinary infections. There were only 5 episodes of MDRE infections in 4 patients: 1 patient developed a cellulitis due to ESBL-producing K. pneumoniae and a bacteremia due to AmpC-hyperproducing E. cloacae; 1 patient had bacteremia due to carbapenemase-producing E. cloacae; 1 patient a urinary infection due to carbapenemase-producing K. oxytoca and 1 patient a urinary infection due to ESBL-producing C. freundii.

Conclusions: 1. In patients with Allo-SCT, intestinal colonisation by MDRE was more frequent after transplantation than before transplantation. 2. All MDRE infections occurred in patients with intestinal colonisation either before or after of the infection episode.

Surveillance and molecular typing of carbapenem-resistant Enterobacteriaceae in neonatal intensive care units in Italy

Marilena Agosta *, Daniela Bencardino 2, Francesca Andreoni 2, Marta Argentieri 1, Barbara Lucignano 1, Livia Mancinelli 1, Manuela Onori 1, Laura Pansani 1, Annamaria Sisto 1, Mauro Magnani 2, Paola Bernaschi 1

1 Bambino Gesù Children’s Hospital - IRCCS, Microbiology Unit, Laboratory Department, Rome, Italy, 2 University of Urbino “Carlo Bo”, Department of Biomolecular Sciences, Fano, Italy

Background: Infections with carbapenem-resistant Enterobacteriaceae (CRE), especially Klebsiella pneumoniae and Escherichia coli, are a serious threat for neonatal intensive care units (NICU). The under-developed immune system of patients and the limited treatment options increase the associated risk. The present study was firstly aimed to estimate the prevalence of CRE strains among the hospital settings and then to investigate their molecular aspects.

Materials/methods: Between 2017 and 2019, 100 CRE strains were isolated from rectal swabs of newborn patients at the microbiological laboratory of Bambino Gesù Children’s Hospital in Rome (Italy). Strains were identified by mass-spectrometry (MALDI-TOF, Bruker) and their antibiotic susceptibility was firstly determined with Vitek 2 system (bioMérieux) according to the EUCAST breakpoints. The Xpert Carba-R (Cepheid) assay was used to detect the resistance determinants and the PCR-based replicon typing (PBRT 2.0, Diatheva Srl) was applied to distinguish the incompatibility groups (Inc). For each strain representative of a PBRT pattern, the multilocus-sequence typing analysis (MLST) was performed.

Results: Fifty-seven strains were identified as K. pneumoniae and 43 as E. coli and all were carbapenem-resistant. \textit{bla}_{NDM} gene was the predominant with 56 single detections (56%) and in 30 strains it was combined with \textit{bla}_{KPC}. A preliminary PBRT analysis of 32 strains revealed the prevalence of IncA/C group widely distributed also in A/C, R, FIIK, FIB KQ and FIB, A/C, FII patterns detected as the predominant multireplicon patterns. Among the 14 PBRT profiles, 8 isolates were selected for MLST: 8 sequence types (ST) were distinguished showing a very high variability. Within them, the ST395 and ST131 are well-known in the global scenario whereas the ST307 and ST101 are recently described as emerging clones, also in paediatric wards.

Conclusions: Based on these data, more attention must be given to the high prevalence of CRE circulating in NICU. Their molecular features highlight the need to implement control measures to avoid their spread among the clinical wards as well as possible complications for the treatment of newborn infections. Furthermore, the application of molecular typing methods in hospitals can be helpful to monitor the diffusion of high-risk clones.

Country-specific approaches to latent tuberculosis screening and its current effectiveness in migrants to Europe

Kieran Rustage1, Ioana Margineanu2, Laura B. Nellums3, Ymkje Stienstra2, Delia Goletti4, Teymur Noori5, Dominik Zenner6, Manish Pareek7, Kristina Langholz Kristensen8, Jon S. Friedland3

1St George's University of London, University of London, London, United Kingdom, 2University of Groningen, Groningen, Netherlands, 3St George's University of London, University of London, London, United Kingdom, 4National Institute for Infectious Diseases, Rome, Italy, 5ECDC, Stockholm, Sweden, 6IOM, Brussels, Belgium, 7University of Leicester, Leicester, United Kingdom, 8University of Copenhagen, Copenhagen, Denmark

Background: Migrants (defined as ‘foreign born’ individuals) are disproportionately affected by tuberculosis in many low-incidence countries, with most active tuberculosis arising from reactivation of latent tuberculosis infection (LTBI). New ECDC guidance suggests systematic testing and treatment for LTBI be offered to migrants, with consideration given to effective implementation along the pathway of care ensuring treatment adherence and completion, yet there is an urgent need for more research and clarity around effectively delivering LTBI screening to migrant populations.

Materials/methods: We did a systematic review and meta-analysis to explore treatment uptake and adherence among migrants in LTBI screening programmes globally. The protocol was PROSPERO registered (CRD42019140338) and follows PRISMA guidelines. We did a semi-structured questionnaire survey of experts in 32 EU/EEA countries and Switzerland (MOH or Public Health, identified through ESGITM and ESGMYC networks) exploring views and concerns around current screening approaches, diagnosis, and management.

Results: 55 studies were included in the review, including data on 30,190 migrants. 51% (95% CI = 40-62%; I² = 99.6%) of migrants testing positive in a screening programme go on to initiate and complete treatment. 71% (95% CI = 0.68-0.75; I² = 98.3%) of migrants who do initiate treatment for LTBI ultimately complete treatment. A variety of both patient and provider-linked factors account for migrants not initiating and completing treatment.

Survey data show that many EU/EEA countries do not target LTBI screening at migrants from high-burden TB countries. Of those that do, screening is voluntary, predominantly focused on young migrants (0-18 years) originating from high-burden countries (the definition of which varies by country), involves either TST or IGRA, with first-choice treatment being RIF + INH for 3 months. Experts felt that migrants were a group with higher drop-out rates, and stressed the need to raise awareness about LTBI screening in migrant populations.

Conclusions: Migrants have low treatment completion rates for LTBI. Greater focus must be given to designing and delivering effective LTBI programmes to migrants if we are to improve health and support global TB eradication.

Abstract 4813

**Characteristics and trends of recently HIV infected individuals in Estonia in 2013-2017**

Ene-Ly Jõgeda*, Radko Avi¹, Paudkar Merit¹, Pilleriin Soodla¹², Taavi Päll¹, Eveli Kallas¹, Heli Rajasaar¹, Kristi Rüütel¹, Irja Lutsar¹, Kristi Huik¹⁴

¹University of Tartu, Institute of Biomedicine and Translational Medicine, Tartu, Estonia, ²Tartu University Hospital, Department of Infectious Diseases, Tartu, Estonia, ³National Institute for Health Development, Tallinn, Estonia, ⁴National Institutes of Health, HIV Dynamics and Replication Program, National Cancer Institute, Frederick, United States

**Background:** The number of new HIV diagnoses in Estonia has remained high with majority of infections being diagnosed among people who inject drugs (PWID) and heterosexuals. Knowing the proportion of recent infections is essential for understanding the course of our epidemic. Thus, we aimed to determine and compare the rates of recent infections among newly HIV-diagnosed individuals using HIV-1 limiting antigen avidity assay (LAq).

**Materials/methods:** All individuals diagnosed with HIV within the years of 2013 (n=325), 2015 (n=269), and 2017 (n=219) were included in the study. Residual samples (289 in 2013, 184 in 2015, and 214 in 2017) from Estonian HIV reference laboratory were tested using LAq with a median duration of recent infection of 130 days. Clinical and demographic data were obtained from Estonian Health Board, hospital records, and Estonian HIV positive patients’ database.

**Results:** Based on LAq, 128 (44.3%), 73 (39.3%), and 73 (34.1%) individuals were classified as recently infected in 2013, 2015, and 2017, respectively (Table). During study period, the proportion of recent infections decreased (44.3% vs 34.1%, p=0.022). The median age of recently infected individuals increased (30 vs 36, p=0.001), but the proportion of men remained similar. The proportion of PWID decreased over the years (25% vs 8%, p=0.004) while the proportion of heterosexuals remained roughly the same. However, self-reported risk factor was unknown in 48% of recently infected individuals in 2017.

Molecular genetic analysis of population of dermatophyte fungus *Trichophyton rubrum*

Ivan Mikhailovich Pchelin¹, Daniil Azarov¹, Maria Churina², Sofya Romanyuk², Yuri Mochalov¹, Galina Chilina¹, Svetlana Apalko², Natalya Vasilyeva*¹, Anastasiya Taraskina¹

¹North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation, ²City Hospital No. 40, Saint Petersburg, Russian Federation

**Background:** *Trichophyton rubrum* is an important causative agent of tinea unguium and tinea pedis worldwide. It is clonal fungus with remarkably low genetic variability. We studied population structure of *T. rubrum* to facilitate epidemiological studies on a global scale.

**Materials/methods:** Species identification of *T. rubrum* isolates was done by ribosomal ITS region sequencing. We performed typing of simple sequence repeats (SSR, also known as microsatellites) in 67 clinical *T. rubrum* isolates from Saint Petersburg and Yekaterinburg, Russia by original assay including 8 previously published and 4 original loci. TERG_02941 genotype was determined by TaqMan SNP genotyping assay with allele-specific probes. Six representative strains, occupying the whole span of SSR typing-based NJ tree were selected for whole genome sequencing by Illumina MiSeq technology.

**Results:** All studied isolates from Russian sample harbored the same ITS region genotype, identical to that one deposited in GenBank under accession number KT285224. SSR typing revealed three major groups of Russian isolates. WGS-based tree of *T. rubrum* sensu stricto isolates contained well-supported monophyletic branch of TERG_02941 793A isolates and two branches of 793G isolates. The TERG_02941 793A branch included West European, Russian and North American strains. The first TERG_02941 793G clade contained East Asian, South-East Asian, North American and Russian isolates, whereas the second TERG_02941 793G clade contained West European and Russian strains.

**Conclusions:** Population of *T. rubrum* consists of cosmopolitan genetic lineages. It means that tracking global spread of *T. rubrum* genetic lines is feasible.

Abstract 4815

Analysis of the evolution of the rate and the associated factors of antiretroviral treatment switch due to intolerance symptom on children in France

Laure Cohen1*, Josiane Warszawski2, Jerome Le Chenadenec1, Pierre Frange3, Veronique Avettand-Fenoel4, Jeanne Sibiude4, Catherine Dollfus6, Marion Caseris1, Albert Faye1

Background: For children living with HIV, cART is recommended from diagnosis. Switch in cART may be related to toxicity or intolerance, whose rate is poorly analysed and understood for infected children. The aim of this study is to estimate rate of antiretroviral therapy switches over time, to analyze calendar effect and to derive which therapeutic strategy can be linked to a switch for toxicity or intolerance. The data source is a National ANRS EPF-C010 cohort of HIV infected children and treated from 2005 to 2018.

Materials/methods: The incidence rate of switches is estimated with Poisson models. The probability of the first switch is estimated with the Kaplan Meier method, and associated factors are identified with a competitive risk model.

Results: The incidence rate of cART switch is 31.8 [30.2-32.7] per 100 person-years. The probability of switching the first treatment is 59.7% [56.1 - 63.3] at 3 years. The incidence rate of switching for toxicity or intolerance decreases over time with an IRR per year of 0.89 [0.85-0.93], p = 0.01. In children under 6 months, the probability of switching first treatment for toxicity tends to decrease after 2007 compared to 2005-07 (3.6% versus 2.1% at 2 years, p = 0.06). Hematologic or mitochondrial toxicity represents 25% of the causes of toxicity switches, all related to AZT. The probability of switching first treatment containing old NRTIs (like AZT) is 17.2% versus 4.3% for recent NRTIs; p = 0.24.

Conclusions: The decrease over time of the risk of switching cART for toxicity or intolerance in children living with HIV, treated for the first time between 2005 and 2018, is reassuring for the care of children.

Pharmacodynamic properties of minocycline monotherapy and combined with polymyxin B in a lung model in neutropenic mice

Heleen Van Der Spek1, Wendy Kloezen1, Aart Van Der Meijden1, Marian Ten Kate1, Johan W. Mouton1, Anouk Edwina Muller1,2, Joseph Meletiadis1,3, Sanne Van Den Berg*1

1Department of Medical Microbiology and Infectious Diseases, Erasmus MC University Medical Centre Rotterdam, Rotterdam, Netherlands, 2Department of Medical Microbiology, Haaglanden Medical Centre, The Hague, Netherlands, 3Clinical Microbiology Laboratory, Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Antimicrobial resistance is a growing problem worldwide. Given the shortage in development of new antibiotics against multi-drug resistant bacteria, there is a growing need to optimize the use of old antibiotics. Combination therapy of existing antibiotics could be an auspicious approach. We therefore investigated the pharmacodynamic (PD) properties of the combination of minocycline and polymyxin B (PMB) against *Klebsiella pneumoniae* in a lung infection neutropenic animal model.

Materials/methods: 10⁶-10⁷ CFU of 3 *K. pneumoniae* isolates (ATCC43816, 74 and 104) with minocycline/PMB MICs 4/0.5, 2/2 and 2/2 mg/L were intranasally administrated in cyclophosphamide-induced neutropenic mice. 2h after infection mice were treated with 2-64 mg/kg q6h, 4-128 mg/kg q12h or 128-256 mg/kg q24h of minocycline alone. For combination therapy mice were treated with 4-128 mg/kg q6h minocycline and 4-16 mg/kg q6h of PMB. After 24h, mice were euthanatized and CFUs were counted with serial quantitative cultures in lung homogenates. The log₁₀ CFU/lung reduction compared to initial bacterial lung burden and 24h placebo-treated mice (dCFU) were calculated for each minocycline and PMB doses.

Results: No stasis was found at any monotherapy or combination regimens. Minocycline monotherapy did not reduce lung bacterial burden compared to placebo-treated mice at any dose except the highest dose of TDD 256 mg/kg. Mean dCFU in minocycline treated q6h vs placebo-treated mice compared to start of treatment was 2.4 vs 2.4, 1.8 vs 2.6 and 1.7 vs 2.0 in *K. pneumoniae* ATCC43816, 74 and 104 infections, respectively. Highest reduction in lung load was found with q24h regimens (mean dCFU -0.9 vs 2.0) in *K. pneumoniae* 104 infected mice. When minocycline q6h up to TDD 512 mg/kg was combined with PMB q6h up to TDD 64 mg/kg in *K. pneumoniae* 104 infected mice, slight reductions in bacterial load were observed compared to monotherapy (mean dCFU -0.8 vs 0.7).

Conclusions: Minimal efficacy of minocycline alone and in combination with PMB was found up to TDD of 256 and 64 mg/kg, respectively against *K. pneumoniae* lung infection model in neutropenic mice. This combination should be studied in more detail in other infection models to explore possible interaction.

Abstract 4817

**Campylobacter concisus prevalence in microscopic colitis: a cultivation study**

Marta Emilie Yde Aagaard*1;2, Karina Frahm Kirk2, Hans Linde Nielsen1;3, Irene Harder Tarpgaard3, Jesper Bach Hansen4, Henrik Nielsen1;2

1University of Aalborg, Department of Clinical Medicine, Aalborg, Denmark, 2Aalborg University Hospital, Department of Infectious Diseases, Aalborg, Denmark, 3Aalborg University Hospital, Department of Clinical Microbiology, Aalborg, Denmark, 4Aalborg University Hospital, Department of Gastroenterology, Aalborg, Denmark

**Background:** Microscopic colitis (MC) is an inflammatory bowel disease. Its aetiology remains unknown; but a luminal gut factor is hypothesised to influence the inflammatory response. Any association with gut bacteria is poorly described, although one study found a possible association in patients with prior Campylobacter concisus gastroenteritis, who presented with a MC diagnosis at 6-month follow-up. *Campylobacter concisus* consists of two genomospecies (GS1 and GS2), which may differ in pathogenic potential, as GS2 is better adapted to the gut than GS1. We aimed to investigate the prevalence of *Campylobacter concisus* in clinical samples from MC patients, including the distribution of GS1 and GS2 isolates.

**Materials/methods:** Fifty-five patients with MC were included. All underwent sigmoidoscopy for the collection of mucosal biopsies; saliva and faecal samples were also collected. Samples were cultivated by the filter method for 48 hours at 37°C in both microaerobic and anaerobic conditions. Species identification was confirmed by MALDI-TOF. MC results were compared to 26 comparable healthy controls. Genome sequencing of MC faecal and biopsy isolates was performed with the Illumina MiSeq; 23S rDNA analysis divided isolates into GS1 or GS2.

**Results:** *Campylobacter concisus* was cultivated in 55/55 (100%) saliva, 14/55 (25.5%) faecal and 69/436 (15.8%) biopsy samples of MC patients; and in 18/26 saliva (69.2%, p<0.0001), 3/25 faecal (12%, p=0.17) and 23/182 (12.6%, p=0.31) biopsy samples of healthy controls. By including both microaerobic and anaerobic isolates, a total of 102 saliva, 23 faecal and 123 biopsy MC isolates were cultivated. Preliminary results show, that MC biopsy isolates dominate in GS2 (n=47) compared to GS1 (n=7) p<0.001, whereas faecal isolates divide equally into GS1 (n=9) and GS2 (n=8) p=0.84.

**Conclusions:** To date, this is the largest study to describe *Campylobacter concisus* prevalence in MC. We found a higher prevalence of *Campylobacter concisus* in MC patients than healthy controls, although only significant in saliva samples. In addition, differences in the distribution of GS1 and GS2 isolates in MC samples may lead to varying effects on the gut mucosa. This possible association should be investigated further in future studies to elucidate whether *Campylobacter concisus* contributes to the aetiology in MC.

**Presenter email address:** marta.aagaard@rn.dk
Abstract 4818

Pharmacogenetic approach to the antifungal drug administration: clinical case

Anastasiya Taraskina1, Yuliya Borzova1, Ekaterina Desyatik1, Dobrodeeva Vera2, Nasirova Regina2, Natalya Vasileva*1

1North-western State Medical University named after I.I. Mechnikov, Kashkin Research Institute of Medical Mycology, Saint-Petersburg, Russian Federation, 2V.M. Bekhterev National Medical Research Center Psychiatry and Neurology, Saint-Petersburg, Russian Federation

Background: Several international guidelines nowadays recommend voriconazole as a first choice for the treatment of invasive aspergillosis [IA]. Voriconazole is an azole antifungal drug which is extensively metabolized by several isoforms of the cytochrome P450 (CYP), mainly by CYP2C19 and to a lesser extent by CYP2C9 and CYP3A4. Genetic variations (combination of alleles inherited from each patient) in drug metabolism genes can alter the capacity for biotransformation of a drug and can affect the effectiveness and safety of therapy.

Case report: The patient R. is 73 years old male, diagnosed with chronic pulmonary aspergillosis on the background asthma and COPD for the last 2 years. During this time, the patient was prescribed thrice treatment with voriconazole in a standard dosage for three months. After 10 days of taking voriconazole, side effects appeared, such as headache, dizziness, pain in the epigastric region, which reduces patient adherence to therapy.

Materials/methods: Genomic DNA was isolated from peripheral leukocytes with “Hemolytic” reagent [InterLabService, RF]. Genotyping for the CYP SNVs was performed using real-time PCR by the RotorGene 6000 (Quagen, Germany) according to the manufacturer’s protocol [Syntol, RF].

Results: The patient R. genotyping results are presented in the table. He is homozygous for CYP2C19*4 allele and heterozygous of CYP2C19*2 and *3 variants, which are associated with lower active metabolite exposure and increased risk for serious adverse events. Based on the results of the genetic analysis, the patient is recommended to monitor the concentration of voriconazole in the blood and the selection of an individual drug dose.

**Protection against H9N2 Influenza A(H9N2) virus induced by recombinant M2e-HA2 fusion protein**

Masoud Moghadaszadeh1, Maryam Zeinolabedin2, Mehdi Golchin3, Reza Ghanbarpour3, Hadi Tavakkoli4

1Tabriz University of Medical Sciences, Biotechnology Research Center, Tabriz, Iran, 2Tabriz University of Medical Sciences, Department of Basic Sciences, School of Allied Medical Sciences, Tabriz, Iran, 3Shahid Bahonar University of Kerman, Department of Pathobiology, Kerman, Iran, 4Shahid Bahonar University of Kerman, Department of Clinical Sciences, Kerman, Iran

**Background:** Influenza as an extremely contagious respiratory tract disease is assumed a community health problem. Influenza A virus is a member of the Orthomyxoviridae family that has segmented genome and great antigenic diversity. Influenza viruses possess multiple conserved epitopes that are designed for universal vaccines. One of these epitopes is matrix-2 protein ectodomain (M2e) and the other is HA2.

**Materials/methods:** The gene coding for M2e2-9 and HA21-9 epitopes of influenza virus which are conserved among all subtypes of influenza A viruses, stimulate immune responses of B-cells and T-cells. In this study, we have constructed new plasmids to express above-mentioned epitopes as a single recombinant product. To this aim, two peptide genes of N-terminal M2e [SLLTEVET] and HA2 [GLFGAIAGF] were linked together with a (Gly4Ser)4 peptide linker (SLLTEVETGGGGSGGGGSGGGGSGGGGSGGGGSGGGGSGAIAGF), synthesized, and cloned into pGS-21a vector. Afterwards, the construct was transferred into E. coli BL21 (DE3) cells and induced using isopropyl β-D-1 thiogalactoside (IPTG). Immunization of mice with these peptides significantly induced humoral immune responses. Three weeks after the last booster, mice were inoculated intranasally with 1×10^6 EID₅₀ of H9N2 virus.

**Results:** In the present study, the recombinant M2e-HA2 fusion protein gene was cloned into pGS-21a vector. The results of sequencing showed that this gene was properly cloned in vector. Also, SDS-PAGE electrophoresis of purified protein exhibited a strong single band. Furthermore, Western blot analysis indicated a single band in correct position. Real-time RT-PCR studies showed reduction of virus in BALB/c mice lung tissues. Our study indicated that this protein could protect mice against H9N2 virus.

**Conclusions:** The recombinant M2e-HA2 fusion protein characterizes a potential candidate for influenza vaccine studies in animal model. According to the findings, the M2e-HA2 fusion protein induced humoral immunity responses. The findings of this study suggest that the recombinant M2e-HA2 fusion peptide which is economical to yield can be used for induction specific antibodies responses. The results of the current study showed that this protein can protect mice by decreasing virus shedding.

A new ultra-fast specimen preparation method for SEM visualization of bacterial biofilms

Igor Chebotar*1, Anastasia Subbot2, Yuliya Bocharova3, Natalia Fedorova4, Ivan Novikov5

1Pirogov Russian National Research Medical University, Moscow, Russian Federation, 2Research Institute of Eye Diseases, Moscow, Russian Federation, 3National Medical Research Center for Children’s Health, Moscow, Russian Federation, 4Pirogov Russian National Research Medical University, Moscow, Russian Federation, 5Research Institute of Eye Diseases, Moscow, Russian Federation

Background: Fast detection of bacterial biofilms is an important problem of clinical microbiology. Scanning electron microscopy (SEM) has been known to visualize microbial biofilms with a high quality. However, the SEM’s practical application is limited to long and complex specimen preparation. The current investigation demonstrates capabilities and benefits of a new biofilm preparation method for SEM based on staining/fixation with neodymium chloride (NdCl₃).

Materials/methods: The study was performed on 48h-old Staphylococcus epidermidis ATCC 12222, Staphylococcus aureus ATCC 29213, and Pseudomonas aeruginosa ATCC 27853 biofilms. The biofilms were formed on polystyrene disks. The disks with the biofilms were rinsed with isotonic sodium chloride, treated with 1% NdCl₃ (BioRee kit, Glaucon, Russia), 20 min, 37°C, and rinsed with deionized water. No additional fixation and dehydration of the specimens were done. The specimens were analyzed using the scanning electron microscope (EVO LS10; Zeiss), the low vacuum mode (70 Pa), the BSE mode.

Results: The NdCl₃ treatment has resulted in SEM high-quality visualization of bacterial cells and extracellular matrix in S. epidermidis, S. aureus and P. aeruginosa biofilms. The bacterial cells retained their shapes and sizes despite low vacuum (70 Pa) inside of the scanning electron microscope. The staining with NdCl₃ contrasted not only the cellular borders, but also intracellular structures (intracellular septa). The image of extracellular matrix was unusual: matrix looked like a volumetric substance without discrete “building blocks”. The typical SEM image of NdCl₃-stained S. epidermidis biofilm is presented in Figure 1. The staining intensity of NdCl₃-treated bacterial cells was variable on the images. Phosphate anion is known as the most significant binding site for neodymium. Therefore, we hypothesize the intensity of cell staining directly correlates with phosphate anions, reflecting bacterial metabolic activity.

Conclusions: The NdCl₃ staining of bacterial biofilms is the fast, simple and informative method of specimen preparation for SEM visualization. The NdCl₃ treatment does not require complete dehydration and ensures biofilm stabilization under the low vacuum during SEM imaging. The most interesting findings are the SEM imaging of undersurface cellular structures and the volumetric visualization of extracellular biofilm matrix.

Cannabidiol synergic antimicrobial activity combined with polymyxin B (PB) against PB susceptible and resistant Gram-Negative bacilli

Nathalia De Lima Martins Abichabki1, Luísa Zacharias1, Tania Ogasawara1, Amanda Seribelli1, Juliana Falcão1, Antonio Zuaníi, Jaime Hallak2, José Alexandre Crippa2, Ana Lucia Darini1, Leonardo Andrade1

1Faculdade de Ciências Farmacêuticas de Ribeirão Preto - USP, Ribeirão Preto, Brazil
2Faculdade de Medicina de Ribeirão Preto - FMF-USP, Ribeirão Preto, Brazil

Abstract third-party references: Research Grant from Pró-Reitoria de Pesquisa (PRP) – Universidade de São Paulo (USP) [PRP-USP, 18.1.796.60.2 grupo 057], Nathália Abichabki was supported by master fellowship [CAPES, 88887.369851/2019-00]. Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil (CAPES) – Finance Code 001.

Background: Polymyxins have been used as agents of last resort in the treatment of bacterial infections by carbapenem-resistant Gram-negative bacilli (GNB). Cannabidiol (CBD) is a major phytocannabinoid from Cannabis sativa and it has shown antimicrobial activity against Gram-positive bacteria, but not against Gram-negative bacteria. The objective of the study was to investigate CBD synergistic/antagonistic activity combined with Polymyxin B (PB) against GNB.

Materials/methods: Carbapenem-resistant, PB susceptible, PB-resistant (plasmid-MCR-1 and chromosomal mutation) and intrinsic PB-resistant GNB were evaluated. Minimal inhibitory concentration (MIC) of PB was determined using broth micro-dilution method, two-fold serial dilution (256-0.01 mg/L), combined with ultrapure CBD (99.9%) (256 µg/mL) against GNB. A minimal three-fold difference in the PB MIC values was considered as synergistic/antagonistic CBD effect. Additionally, in vitro phagocytic capacity and/or bacterial survival was verified in U937 human macrophages, in the presence and absence of CBD (256 µg/mL), using colony forming units (CFU) to determine viable internalized bacteria after phagocytosis period (5 hours).

Results: PB combined with CBD showed highlighted synergic antimicrobial activity (PB MIC decrease) against: PB-resistant (non MCR-1) KPC-producing Klebsiella pneumoniae [32 to ≤ 0.5 µg/mL]; K. pneumoniae ATCC 13883 [8 to 0.125 µg/mL]; Stenotrophomonas maltophilia ATCC 13673 [4 to 0.06 µg/mL]; carbapenem-resistant Acinetobacter baumannii [CRAB] (0.5 to ≤ 0.01 µg/mL); Escherichia coli ATCC 25922 [0.25 to ≤ 0.01 µg/mL]; ESBL-producing E. coli [0.5 to ≤ 0.01 µg/mL]; NDM-producing K. pneumoniae NCTC 13443 [1 to 0.06 µg/mL] and A. baumannii ATCC 19606 [0.5 to ≤ 0.06 µg/mL]. Surprisingly, PB combined with CBD also demonstrated antimicrobial activity against intrinsic PB-resistant Edwardsiella tarda ATCC 15947 [≥ 8 to 0.03 µg/mL] and Serratia marcescens ATCC 13880 (> 8 to ≤ 0.01 µg/mL). Regarding the in vitro phagocytic capacity and/or bacterial survival in the presence of CBD, there was decreased CFU recovery of NDM-producing K. pneumoniae, on the other hand, increased CFU recovery of CRAB, however, further immunological studies are necessary to conclude this issue.

Conclusions: CBD shows synergic antimicrobial activity combined with PB against several GNB, showing perspective of combined antimicrobial therapy, minimizing PB inherent neurotoxicity and nephrotoxicity. Moreover, this association also showed activity against intrinsic PB-resistant bacteria.

Use of antimicrobial stewardship smartphone applications by physicians and appropriate prescribing in hospitals: a systematic review

R.I. El Helou*, Dimard Foudraine, Gaud Catho, Annabel Peyravi Latif, Neliianne Verkaik, Annelies Verbon

1Department of Medical Microbiology and Infectious Diseases, Erasmus Medical Center, Rotterdam, Netherlands, 2Division of Infectious diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, 3Department of Medical Sciences, Uppsala University, Uppsala, Sweden

Background: Antimicrobial stewardship (AMS) promotes appropriate use of antimicrobial drugs and reduces antimicrobial resistance. Technological advancements have resulted in the development of smartphone applications (apps) facilitating AMS. However, user experience, uptake and impact of AMS apps on antimicrobial prescribing is unclear.

Materials/methods: A systematic review was conducted. EMBASE, MEDLINE (Ovid), Cochrane Central, Web of Science and Google Scholar databases were searched for relevant quantitative and qualitative studies regarding AMS apps in hospital settings published until February 28th 2019. Manuscripts were independently screened, selected after reaching consensus and subsequently assessed by two investigators for eligibility.

Results: Thirteen studies met the eligibility criteria of which none were randomized controlled trials. Overall, methodological study quality was considered low to moderate. The main outcomes were process indicators such as total number of app downloads, average monthly app accessions and accessed guidelines in seven studies, guideline adherence in four studies and user experience in five studies. Guidelines were more frequently accessed by app than by desktop if available on both. Average app use increased over time in one study but decreased in another. In general, adherence to treatment guidelines increased significantly for a number of indications after app implementation. In addition, bacterial susceptibility to several Watch and Reserve antibiotics changed significantly post-intervention in one study. Most users considered app use to be easy, quick and preferred it over guideline access by web viewer or booklet. However, some physicians regarded app use in front of colleagues or patients as unprofessional.

Conclusions: The available evidence is scarce, but suggests that the use of AMS apps increased guideline adherence and appropriate antimicrobial prescribing. For optimal adherence to antimicrobial guidelines, use of an AMS app should therefore be considered as a tool in the daily workflow.

Resistance among urinary tract infection pathogens collected in Europe during 2018

Ian Critchley*, Nicole Cotroneo1, Michael Pucci1, Akash Jain1, Rodrigo E. Mendes2

1Spero Therapeutics, Cambridge, United States, 2JMI Laboratories, North Liberty, United States

Background: Escherichia coli (EC), Klebsiella pneumoniae (KP) and Proteus mirabilis (PM) are urinary tract infection (UTI) pathogens where increasing prevalence of extended spectrum β-lactamase (ESBL)-producing organisms continues to compromise oral agents. Many ESBL-producing pathogens exhibit co-resistance (co-R) to the fluoroquinolones (FQs) and trimethoprim-sulfamethoxazole (TMP-SMX) making the management of UTIs challenging outside the hospital. The aim of the current study was to assess the prevalence of ESBL phenotypes and the extent of co-R to the FQ’s and TMP-SMX among UTI pathogens.

Materials/methods: 766 EC, 260 KP and 104 PM collected from UTIs in 18 countries in Europe in 2018 were evaluated in the SENTRY Surveillance Program for susceptibility to various agents. All isolates were centrally tested and results interpreted according to EUCAST criteria.

Results: Among EC, KP and PM the prevalence of ESBL phenotypes were 17.5%, 32.7% and 10.6%, respectively. Among all EC, resistance (R) rates for cefuroxime (CEF), levofloxacin (LEV) and TMP-SMX were 20.0%, 21.8% and 32.7%. All EC remained 100% susceptible (S) to meropenem. ESBL EC showed R rates of 99.2%, 66.4% and 67.9% for CEF, LEV and TMP-SMX, respectively. For all KP, R rates to CEF, LEV and TMP-SMX were 46.5%, 32.2% and 40%, respectively and to MER was 7.7%. For ESBL KP the R rates to CEF, LEV, TMP-SMX and MER were 98.2%, 69.1%, 78.6% and 17.9%, respectively. Among PM, R rates for CEF, LEV and TMP-SMX were 9.7%, 26.0% and 38.5%, respectively and all isolates were 100% S to MER and for ESBL PM R to CEF, LEV and TMP-SMX were ≥90.9%.

Conclusions: EC was the most prevalent UTI pathogen where R to CEF, LEV and SXT was ≥20% for all isolates and ≥66.4% for ESBL phenotypes of EC. R to oral agents was ≥32% for all KP and ≥69% among ESBL phenotypes of KP. Among PM R to LEV and TMP-SMX was ≥34%. MER exhibited greatest activity against UTI isolates and low co-R to oral agents. New oral agents with the spectrum and potency of the carbapenems could help fulfill an unmet need for new options to treat MDR EC, KP and PM from UTIs.

Antibiotic use prior to seeking medical care in patients with persistent fever in four low- and middle-income countries

Brecht Ingelbeen*1, Kanika Deshpande Koirala2;3, Kristien Verdonck1, Barbara Barbé1, Déby Mukendi Mulumba4;5, Thong Phe6, Sayda El Safi7, Emmanuel Bottieau1, Marianne Van Der Sande1;8, Marleen Boelaert1, François Chappuis9, Jan Jacobs1;10

1Institute of Tropical Medicine Antwerp, Antwerpen, Belgium, 2B.P. Koirala Institute of Health Science, Dharan, Nepal, 3University of Geneva, Institute of Global Health, Geneva, Switzerland, 4Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of Congo, 5Université de Kinshasa, Département de Neurologie Tropicale, Kinshasa, Democratic Republic of Congo, 6Sihanouk Hospital Center of Hope, Phnom Penh, Cambodia, 7University of Khartoum, Faculty of Medicine, Khartoum, Sudan, 8Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 9Hôpitaux Universitaires de Genève (HUG), Division of Tropical and Humanitarian Medicine, Genève, Switzerland, 10KU Leuven, Department of Microbiology and Immunology, Leuven, Belgium

Background: Community-level antibiotic use contributes to antimicrobial resistance but is rarely monitored in low- and middle-income countries (LMIC). We describe prior antibiotic use in patients consulting with persisting fever in four LMICs.

Materials/methods: The NIDIAG project developed clinical guidance for the diagnostic work-up of patients with >1 week of fever in healthcare facilities in Cambodia (urban), DR Congo (rural), Nepal (one rural; one urban) and Sudan (rural). We recorded participants’ antibiotic use within four weeks before consultation and report its frequency and risk factors. We categorized antibiotics according to the WHO Access/Watch/Reserve (AWaRe) classification (2017).

Results: We recruited 382 patients (median 47 years; IQR 35-58) in Cambodia, 300 (median 19y; IQR 7-39) in DRC, 583 (median 34y; IQR 20-50) in Nepal and 674 (median 35y; IQR 20-48) in Sudan. Overall, 348 (17.9%) used ≥1 antibiotic: 6.0%, 7.0%, 30.0% and 19.1% in Cambodia, DRC, Nepal and Sudan respectively. Use of multiple antibiotics was more frequent in Cambodia (33.3%-38.9%) than Sudan (10.9%). 294 (84.5%) patients recalled the specific antibiotic used: most frequent were cephems (172; 40.3% of reported antibiotics), macrolides (72; 16.8%), fluoroquinolones (51; 11.9%) and beta-lactamase-labile penicillins (51; 11.9%). Cephem use was higher in Nepal (54.5%) than elsewhere (14.8%-24.3%). Beta-lactamase-labile penicillins were frequently used in Sudan (41.8%) and DRC (22.2%), but rarely/not in Nepal and Cambodia (3.2%-0%). Fluoroquinolone use ranged from 8.7% (DRC) to 21.6% (Cambodia). ‘Watch’ antibiotics use ranged from 23.7% (DRC) to 82.4% (Nepal; Figure). Parenteral administration ranged from 5.9%-66.7% between study sites. Antibiotic use was more frequent among young patients (5.17y; Risk ratio 1.5, 95%CI 1.23-1.83), patients diagnosed with urinary tract infection (RR 1.38, 95%CI 1.04-1.85) or visceral leishmaniasis (RR 1.49, 95%CI 1.03-2.14; restricted to Sudan and Nepal). Patients had started antibiotics a median 5 days (IQR 2-10) before the consultation, ranging from 3 days (DRC) to 8 days (Sudan).

Conclusions: We observed large differences in the frequency and choice of (‘Watch’) antibiotics in four LMICs. Differences between countries can only partially be explained by demography and disease burden. Healthcare seeking, health system characteristics, including training, (lack of) guidelines, and ‘Watch’ antibiotics’ availability are other likely contributors.

Abstract 4826

Molecular characteristics and clonal diversity of carbapenemase-producing *Klebsiella pneumoniae* isolated from blood culture in patients with haematological malignancies

Svetlana Khrulnova*1, Galina Klyasova2, Kristina Tandilova3, Anna Korobova1, Anastasia Fedorova Mironova1, Irina Frolova1, Bella Biderman1

1National Research Center for Hematology, Moscow, Moscow, Russian Federation

**Background:** Carbapenem non-susceptible *Klebsiella pneumoniae* are associated with high morbidity, mortality, prolonged hospitalization patients. The aim of this study was to evaluate the genetic variability in carbapenemase-producing *K.pneumoniae* (CP-*K.pneumoniae*), isolated from blood cultures in patients with haematological malignancies.

**Materials/methods:** This study included *K.pneumoniae* isolated from blood cultures in haematological patients [2003-2018]. Susceptibility to meropenem was determined by the broth microdilution method [CLSI,2018]. Carbenapenemase genes (*bla*<sub>OXA-48-like</sub>, *bla*<sub>KPC-like</sub>, *bla*<sub>NDM-like</sub>, *bla*<sub>VIM-like</sub> and *bla*<sub>IMP-like</sub>), *bla*<sub>CTX-M</sub> genes and genetic markers for hypervirulence (*iucA*, *rmpA*, *rmpA2*) were detected by PCR. Multiplex PCR was performed to detect for K1,K2,K5,K20,K54, and K57 serotype-specific alleles, that are commonly used as markers for hypervirulence *K.pneumoniae* [hvKp]. Multilocus sequence typing [MLST] for CP-*K.pneumoniae* were performed by PCR and sequencing of 7 housekeeping genes. Allelic profiles and sequence types [STs] were assigned at the Institut Pasteur MLST database.

**Results:** A total of 494 *K.pneumoniae* isolates were evaluated, of those 83(16.8%) isolates were CP-*K.pneumoniae*. The prevalent carbapenemase genes were *bla*<sub>OXA-48-like</sub>(76/83;91.6%) followed by co-harboring *bla*<sub>OXA-48-like</sub> and *bla*<sub>NDM-like</sub>(5/83;6%), and *bla*<sub>KPC-like</sub>(2/83;2.4%). The *bla*<sub>CTX-M</sub> genes were detected in 79.5%(n=66) CP-*K.pneumoniae* isolates. Of those 60(72.3%) isolates carried only *bla*<sub>CTX-M-1-like</sub> and 6 (7.2%) isolates harbored *bla*<sub>CTX-M-1-like</sub> and *bla*<sub>CTX-M-9-like</sub> simultaneously. Among CP-*K.pneumoniae*, 40(48.2%) carried at least one virulence gene (*iucA*, *rmpA* or *rmpA2*)[Table]. These isolates were considered hvKp. MLST revealed 13 different STs, the most common types were ST395 (25/83;30.1%) and ST23 (19/83;22.9%) following by ST11 (12/83;14.5%) and ST377 (10/83;12%). The ST14 and ST3229 were represented by five isolates each and other 7 STs (ST13,ST14,ST86,ST218,ST258,ST590,ST874) were represented by one isolate each. Virulence genes were detected in 89.5% ST23 isolates. Genes of *iucA* and *rmpA2* were identified in 89.5% ST23 vs 40% ST395(p<0.0014), 16.7% ST11(p<0.0001) and 10% ST377(p<0.0021). Significant difference in gene *rmpA* detection was not found. Capsule type K57 was identified in all ST23 isolates (100% vs 0% in ST395,p<0.0001) whereas K2 was associated with ST395 isolates (56% vs 0% in ST23,p<0.0001).

**Conclusions:** The dominant carbapenemase genes were *bla*<sub>OXA-48-like</sub>(91.6%) in CP-*K.pneumoniae* isolated from blood cultures. MLST revealed the high genetic diversity of CP-*K.pneumoniae* isolates. The prevalent STs were ST395 (30.1%) and ST23 [22.9%]. ST23 isolates carried more virulence genes then ST395, ST11 and ST377 isolates.

Abstract 4827

Rapid molecular Chlamydia trachomatis/Neisseria gonorrhoeae testing is now a reality
Barbara Van Der Pol*, Lashonda Crane, Stephanie N Taylor, Joel Lebed, Aaron Ermel, Leandro Mena, Candice Mcneil, Adam Sukhija-Cohen

1University of Alabama at Birmingham, Birmingham, United States, 2Planned Parenthood Gulf Coast, Houston, United States, 3Louisiana State University Health Sciences Center, New Orleans, United States, 4Planned Parenthood Souther Pennsylvania, Philadelphia, United States, 5Indiana University School of Medicine, Indianapolis, United States, 6University of Mississippi Medical Center, Jackson, United States, 7Wake Forest Health Center, Winston, United States, 8AIDS Health Foundation, Los Angeles, United States

Background: Since the first molecular tests were available, STI control programs have demanded rapid, on-site molecular diagnostics for CT/NG. The nearest solution to this problem to date is a highly accurate test that provides a result in 90 minutes. The binx io system is an easy-to-use, rapid, molecular point-of-care platform that has a sample to result time of about 30 minutes. The io is portable, fully automated and has been developed to simultaneously detect CT and NG from vaginal swabs or male urine specimens. We compared the performance of this rapid point of care molecular assay to central laboratory CT/NG tests.

Materials/methods: Female patients enrolled in the study had four vaginal swabs taken which were evenly split between self- or clinician-collected using the io vaginal swab specimen collection kit and the collection devices from three commercially available nucleic acid amplification tests (NAATs). For male samples, first-void male urine was aliquoted into the io urine specimen collection kit and similarly into those of each of the three comparator NAATs. Testing on comparators was performed in a single laboratory according to the manufacturer’s instructions for use. Patients were considered infected with CT or NG if two of the three comparator tests gave positive results for that organism. The io samples were tested on-site or sent to central laboratories. All io testing was performed within seven days of collection. Testing with the io system was performed in the vast majority by non-laboratory trained clinical personnel as well as by laboratorians.

Results: Samples were tested from 726 and 223 consenting women and men, respectively. For CT, sensitivity was 96.6% (95%CI 88.5-99.1%) and 93.9% (80.4-98.3%) for women and men, respectively, while specificity was >99.3% for both sample types. For NG, sensitivity was 100% (86.7-100%) and 100% (87.1-100%) for women and men, with specificities of 100% for both sample types.

Conclusions: A rapid, highly accurate NAAT is now available that can be performed in point-of-care clinical settings and by non-laborators. This assay has the potential to drastically improve the ability to test and treat in the same visit which will reduce transmissibility and improve antimicrobial stewardship.

Abstract 4828

Understanding discordance between observed and WGS-predicted resistance: a study of amoxicillin-clavulanate in Escherichia coli

Timothy James Davies1, Nicole Stoesser1, Anna Sheppard1, Manal Abuoun2, Philip Fowler1, Jeremy Swann1, Mai Phuong Quan1, Dai Griffiths1, Ali Vaughan1, Marcus Morgan3, Hang Phan2, Katie Jeffery3, Monique Andersson5, Matthew Ellington4, Oskar Ekelund5, Neil Woodford4, Amy Mathers6, Robert A. Bonomo7, Derrick Crook1, Tim Peto1, Muna Anjum2, A. Sarah Walker1

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2Animal and Plant Health Agency, Bacteriology, London, United Kingdom, 3John Radcliffe Hospital, Oxford University Hospitals NHS Trust, Headington, United Kingdom, 4Public Health England, Antimicrobial Resistance and Healthcare Associated Infections Reference Unit, London, United Kingdom, 5Region Kronoberg, Department of Clinical Microbiology, Växjö, Sweden, 6University of Virginia Health System University Hospital, Division of Infectious Diseases and International Health, Charlottesville, United States, 7Case Western Reserve University, Louis Stokes Cleveland Veterans Affairs Medical Centre, Cleveland, United States

Background: Resistance prediction from whole-genome sequencing (WGS) is increasingly seen as a viable alternative to traditional antimicrobial susceptibility testing. However, while some applications work well (e.g. predicting Mycobacterium tuberculosis resistance to first-line treatment), others, such as prediction of amoxicillin-clavulanate resistance in Escherichia coli, are more difficult. Here, resistance is complex: rather than simply being due to presence/absence of beta-lactamases, expression plays a key role. Further, phenotyping is challenging, with significant differences between EUCAST- and CLSI-endorsed reference methods.

Materials/methods: We predicted WGS-based amoxicillin-clavulanate resistance/susceptibility using 261 bacteraemic isolates of E. coli from a single centre, using not only presence/absence of beta-lactamases, but also other known mechanisms of amoxicillin-clavulanate resistance that increase beta-lactamase expression or decrease cell permeability. Resistance/susceptibility predictions were compared with reference-standard replicate phenotyping performed according to both EUCAST and CLSI guidelines.

Results: Concordance between predicted and observed resistance was similar comparing against each of CLSI and EUCAST phenotypes, as at the two reference-standard phenotypes themselves (Figure). Incorrect resistant/susceptible predictions were not random, occurring mostly in isolates with peri-breakpoint MICs (p<0.001). This finding, combined with the unimodal distribution of amoxicillin-clavulanate MICs, suggests that partitioning resistance into binary R/S categories may be poorly representative. We explored this by modelling isolate MIC as a function of its genetic resistance features using mixed models. This demonstrated that some genetic features caused small but potentially additive increases in MIC. These effects in isolation could subtly alter MICs around the breakpoints, but were often masked by the inherent variability of phenotyping, thus explaining the variable peri-breakpoint predictions of the binary WGS-based prediction. Although accurate WGS-based binary resistant/susceptible prediction was sub-optimal, MIC prediction from genotype was not. In an independent test set of 704 E. coli isolates, while WGS-predicted and observed resistant/susceptible phenotype only agreed for 632 (90%) isolates, using only known resistance mechanisms, model predicted MICs were within one doubling dilution [essential agreement] for 684 (97%) isolates.

Conclusions: For amoxicillin-clavulanate, the binary resistant/susceptible paradigm was a key driver of suboptimal prediction performance. This highlights the importance of investigating discordance between WGS-predicted and observed resistance, as it may not always be due to simple phenotype or genotype errors.

Abstract 4832

A multi-centre analysis of the value of systematic screening of influenza virus and vaccination on emergent admissions to a cardiac intensive care unit

Alicia Galar Recalde1*, Miriam Juárez2, Iago Sousa Casasnovas3, Maricela Valerio Minero1, Pilar Catalán1, Pablo Antunez1, Gema Barbeito Castiñeiras1, Silvia Blanco5, Lola Folgueira2, José María García-Acuña3, Antonio Lalueza2, Fernando Lázaro6, Esteban López De Sá1, Lorena Martin1, Elena Muñez Rubio2, Francisca Portillo5, Antonio Ramos Martínez3, Sandra Ofelia Rosillo2, Manuel Martínez-Selles2, Francisco Fernandez-Aviles2, Emilio Bouza1, Patricia Muñoz1

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases Department, Madrid, Spain, 2Hospital General Universitario Gregorio Marañón, Cardiology Department, Madrid, Spain, 3Complejo Hospitalario Universitario de Santiago, Cardiology Department, Santiago de Compostela, Spain, 4Complejo Hospitalario Universitario de Santiago, Clinical Microbiology Department, Madrid, Spain, 5Hospital Universitario Puerta de Hierro, Infectious Diseases Department, Madrid, Spain, 6Hospital Universitario 12 de Octubre, Clinical Microbiology Department, Madrid, Spain, 7Hospital Universitario 12 de Octubre, Internal Medicine Department, Madrid, Spain, 8Hospital Universitario La Paz, Clinical Microbiology Department, Madrid, Spain, 9Hospital Universitario La Paz, Cardiology Department, Madrid, Spain, 10Hospital Universitario Puerta de Hierro, Clinical Microbiology Department, Madrid, Spain

Background: Influenza is a potential inducer of acute cardiac events. However, influenza incidence in patients admitted to a C-ICU, the accuracy of clinical suspicion and the compliance of influenza vaccination of high-risk patients, are unknown. Objectives: to evaluate influenza incidence at C-ICU admission during influenza season, the potential underdiagnosis and vaccination rate.

Materials/methods: Prospective study at 5 tertiary institutions including all patients admitted at a C-ICU during 2017-2018 and 2018-2019 flu seasons. A nasopharyngeal swab was collected at admission from all patients who consented (n=526) and were tested using Xpert® Flu/RSV assay. Clinical data were registered.

Results: Influenza was detected in 39/526 (7.4%) patients (36 FluA, 3 FluB) and initially suspected by the cardiologist in 66.7% of the cases. When compared to patients without influenza, flu positive patients had more acute decompensated heart failure (38.5% vs 23.6%, p=0.03), contact with relatives with flu-like illnesses (28.2% vs 13.9%, p=0.03), antimicrobials use (64.1% vs 31.0%, p<0.01), days of hospitalization (10d vs 5d, p=0.046) and need for non-invasive mechanical ventilation (17.9% vs 5.7%, p<0.01). Reasons for C-ICU admission between both groups were similar. All patients promptly received oseltamivir and no differences were found in mortality between both groups (5.1% vs 4.7%, p=0.36) despite a higher rate of severe presentations in flu patients: myocarditis (7.7% vs 0.8%, p=0.01), respiratory insufficiency needing mechanical ventilation (15.4% vs 5.5%, p=0.01), pericarditis (27% vs 8.8%, p=0.01), and related complications (64.1%). Flu vaccination had been received by 44.7% of the patients admitted to the C-ICU and 53.3% of patients who had a clear indication for it (n=400). Among the group of vaccinated patients those who were immunodepressed showed more flu episodes (16.7% vs 3.2%, p=0.03). Risks factors for no-vaccination despite indication were: younger age (68 vs 74y-o, p<0.01) and less comorbidity (Charlson index 4 vs 5, p<0.01).

Conclusions: Seven percent of patients admitted to the C-ICU during the influenza season had influenza. Only 67% of the influenza cases were suspected at admission and only half of the patients with indication for flu vaccination, had already received the vaccine. A clinical score to recognize influenza in these patients is needed.

Abstract 4833

Optimization of *Mycobacterium avium* complex therapy with synergistic and bactericidal drug combinations

Vidhisha Sonawane*1, Mike M. Ruth1, Lian Pennings1, Jakko Van Ingen3

1Radboudumc, Department of medical microbiology, Nijmegen, Netherlands

**Background:** The standard drug regimen for *Mycobacterium avium* complex (MAC) disease includes 3 drugs- rifampicin, ethambutol and macrolide (REM) along with amikacin for severe or refractory infections. The culture conversion rates of this regimen are 50-70%. Moreover, this regimen is based on clinical-experience more than evidence-based studies. Hence, in this study we explore different drugs- clarithromycin (CLR), rifampicin (RIF), ethambutol (EMB), amikacin (AMK), clofazimine (CFZ), and minocycline (MIN) in two, three, four and five drug combinations to explore different synergistic and bactericidal drug combinations.

**Materials/methods:** The minimum inhibitory concentrations [MIC] of all the antibiotics used in this study against *M avium* ATCC 700898 was determined by broth microdilution. We performed Time–kill kinetic assays (TKA) of all single drugs and combinations against *M. avium* ATCC 700898. Interactions in these combinations were assessed for TK experiments based on effect size and Bliss independence.

**Results:** No single drug could sterilize *M. avium* in the TKAs. Increase in the effect size was seen in all two-drug combinations (+18.72 ± 31.86%), but antagonism was seen in some combinations relative to bliss independence. Three-drug combinations showed an increase in effect size (+12.18 ± 11.46%) than two-drug combinations especially with an addition of CLR or MIN. Three-drug combinations containing CLR and CFZ outperformed REM. In most of the combinations, the addition of a fourth drug showed a diminished increase in effect size (+4.54 ± 3.08%) however, addition of CFZ to REM showed high increase in effect size. Combinations without CLR and RIF had similar effect sizes to 3-drug regimens. The five-drug regimen had a worse effect size than four-drug regimens (-5.54%). Time-kill curves for some of the combinations are shown in the figure below.

**Conclusions:**

1) MAC-PD treatment benefits from multi-drug therapy.
2) Standard drug regimen (REM) may not be the best choice and other combinations should be considered.
3) Beyond three-drug regiments, the added effect size brought by the fourth drug diminishes. Clinical evaluation is needed to warrant the added toxicity in these regimens.

Figure: The above figure shows the TK curves for 1) one, two, three drug combinations and 2) four, five drug combinations.

Application of whole genome sequencing for national surveillance activities

Nicholas Duggett*, Manal Abuoun*, Luke Randall¹, Robert Horton¹, Fabrizio Lemma¹, Jon Rogers¹, Derrick Crook², Chris Teale¹, Muna Anjum¹

¹Animal and Plant Health Agency, New Haw, United Kingdom, ²Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Background: Antimicrobial resistance (AMR) is the ability of microorganisms to resist the effects of an antimicrobial to which they were once sensitive. Increases in AMR are of global concern to human and animal populations as it can lead to treatment failures. If the issue is not addressed it is estimated that millions of lives might be at risk. Whole genome sequencing (WGS) is being implemented widely for determining AMR. This has led EFSA and ECDC to consider its use for harmonised AMR monitoring. Therefore, our aim was to test benefits of using WGS for AMR national surveillance.

Materials/methods: WGS and genomic characterisation was performed on 498 ESBL/AmpC producing Escherichia coli collected on MacConkey+cefotaxime (McC+CTX) or ESBL selective agar. To aid characterisation of mobile-genetic elements, a small subset was subjected to long-read sequencing. The E. coli originated from national and EU pig surveillance studies performed across the UK in 2013, 2015 and 2017.

Results: There was 98% concordance between genotype and phenotype in a subset of isolates, supporting implementation of WGS. The majority of isolates were genotypically multi-drug resistant [MDR]. The proportions of MDR and blaCTX-M-1 harbouring isolates from McC+CTX agar reduced over time, but isolates harbouring blaCMY-2 and AmpC promoter mutations increased. Proportions of MDR isolates from ESBL agar were variable, but numbers of blaCTX-M-1 isolates decreased with other ESBL variants increasing. Genotypic resistances to non-beta-lactam antimicrobials were present in 9-88% of isolates, depending on the antimicrobial. The isolates belonged to multiple STs, demonstrating AMR dissemination. Many AMR genes were located on plasmids showing similarity to plasmids previously isolated from humans, animals or the environment. MDR IncI1 plasmids harbouring blaCTX-M-1 were the most prevalent plasmid types, and demonstrated genomic stability, which could drive transmission and persistence of MDR.

Conclusions: Our research showed that WGS, which EFSA and ECDC are looking to integrate into national surveillance, could provide a wealth of data about trends in AMR gene prevalence, and their mode of transmission and persistence.

Abstract 4837

Anaemia is associated with mortality in patients with left-sided endocarditis: a POET sub-study

Mia Pries-Heje*, Nikolaj IHlemann1, Niels Bruun1, Emil Fosbøl1, Niels Tønder3, Claes Ernst Moser1, Kasper Iversen5,6, Henning Bundgaard1

1Rigshospitalet, Department of Cardiology, København, Denmark, 2Gentofte Hospital, Department of Cardiology, Hellerup, Denmark, 3Northzealnds Hospital - Hillerød, Department of Cardiology, Nefrology and Endocrinology, Hillerød, Denmark, 4Rigshospitalet, Department of Clinical Microbiology, København, Denmark, 5Herlev Hospital, Emergency Department, Herlev, Denmark, 6Herlev Hospital, Department of Cardiology, Herlev, Denmark

Background: Anemia is a common finding in patients with endocarditis – a disease with a high mortality. Despite this, very little is known about frequency, severity and prognostic impact of anemia in patients with endocarditis and treatment follows standard guidelines for treatment of anemia.

Materials/methods: In the Partial Oral versus Intravenous Antibiotic Treatment of Endocarditis (POET) trial, patients with left-sided endocarditis were randomized after stabilization to conventional IV treatment or partial oral antibiotic treatment. Only medically treated patients not undergoing surgical intervention were considered, as the Hgb level after surgery was considered to reflect local transfusion regimens. Patients were classified as having mild anemia at hemoglobin (Hgb) < 8.3 and > 6.0 mmol/l for men and < 7.3 and > 6.0 mmol/l for women, moderate anemia at Hgb between 6.0 and 5.0 mmol/l and severe anemia at Hgb < 5.0 mmol/l.

Results: Four hundred patients were randomized in the POET trial. Hgb level at randomization was available for 237 (95.6%) out of 248 medically treated patients. The median time from diagnosis of endocarditis to randomization was 17 days. In total, 205 (86%) patients had anemia; 140 (59%) patients had mild anemia, 59 (25%) moderate anemia and 6 (2.5%) patients had severe anemia. Patients with moderate or severe anemia were more likely to have renal disease (30.8% vs 11.0%) and had higher CRP concentrations. There was no difference between other baseline characteristics (Table 1). Eleven (16.9%) patients with moderate or severe anemia died within 6 months follow-up as compared to six (3.5%) patients with no or mild anemia (p=0.001).

In logistic regression analysis, moderate or severe anemia was significantly associated with 6-months mortality, with an OR of 5.6 (2.05-17.04) compared to patients with no or mild anemia, (p=0.001). After adjusting for renal disease, CRP, age and gender, moderate or severe anemia was still a significant predictor of 6-months mortality (p<0.001), OR = 4.51 (1.54-14.26), with an area under the curve of 0.79.

Conclusions: In the POET study >85% of patients with left-sided endocarditis and not undergoing surgery had anemia at randomization. Moderate or severe anemia at randomization was an independent predictor of death at 6 months.

Abstract 4838

Automated isolation of microbial DNA from human samples
Helena Block*, Silvia Magyar1, Dominic O’neil1, Markus Sprenger-Haussels1

1QIAGEN GmbH, Hilden, Germany

Background: The influence of the human microbiome on health has been demonstrated in multitudes of studies and is an important area of ongoing investigation for medicine and diagnostics. For these studies it is crucial to have a reliable, reproducible extraction method which is able to extract DNA of all microorganisms with comparable efficiency, while simultaneously depleting inhibitory substances which might disturb subsequent downstream analysis. In addition, the increase in number and size of microbiome studies necessitates automation of these extraction methods. Here, we present the results of automating an established extraction method on a magnetic bead handling instrument.

Materials/methods: Human microbiome samples (stool, buccal swabs, and others) were homogenized and microbial cells (including gram-negative and gram-positive bacteria, fungi, and archaea) were rapidly and efficiently lysed by bead beating in conjunction with chemical lysis. In a subsequent step various inhibitory substances were removed from all kinds of inhibitor-rich sample types including stool and gut samples. Thereafter, inhibitor-free DNA was captured on magnetic silica beads, washed, and eluted on the QIAasympohy SP automated system. Extracted DNA quality was assessed for purity and yield, as well as tested in qPCR and 16S rDNA sequencing experiments.

Results: The automated DNA extraction method was able to efficiently extract microbial DNA from one to 96 samples per run, generating consistent results with no detectable cross-contamination. Extracted microbial DNA displayed no inhibition in qPCR with internal control. 16S rDNA sequencing revealed highly complex communities, measured by alpha diversity (observed operational taxonomic units [OTUs]), being comparable to the manual DNeasy PowerSoil Pro reference method, and higher than other tested methods. Beta diversity indicated that extraction of multiple replicates of the same sample were extremely consistent.

Conclusions: This workflow enables processing of up to 192 human or environmental samples and delivers high-quality DNA for downstream applications such as PCR amplification and NGS analysis in less than one day.

Comparison of analytical performances of the new Qiagen NeuMoDx CT/NG assay with the Abbott RealTime CT/NG assay for detecting Chlamydia trachomatis and Neisseria gonorrhoeae

Sanela Svraka-Latifovic1, Tsira Dzebisasjvili1, Roland Doorn1, Cornelis P. Timmerman1,2, Leendert Bakker1, Roel Nijhuis1, J. Wendelien Dorigo-Zetsma1

1Tergooi - locatie Hilversum, Hilversum, Netherlands, 2Tergooi Hospital, Hilversum, Netherlands, 3Meander Medical Center, Amersfoort, Netherlands

Background: The new NeuMoDx system from Qiagen has been recently introduced. In this study the NeuMoDx CT/NG Assay was compared to the Abbott m2000 Real Time CT/NG assay for detecting Chlamydia trachomatis and Neisseria gonorrhoeae in clinical specimens. Our aim is to compare the performance of the new NeuMoDx CT/NG Assay with that of Abbott RealTime CT/NG assay for male and female clinical (urine and swab) specimen.

Materials/methods: In total 1031 clinical samples and ten quality control samples were tested, 664 were retrospectively and 367 prospectively tested. Sample types included were urine and swab specimens [genital, anal, eye, throat and urethra]. Retrospective study included 120 negative, 543 positive and 1 inhibited sample, while prospective study included 198 negative and 179 positive samples.

Results: Overall agreement between the two assays was 96.64%. In total of 722 positive samples, 27 tested negative and 5 had unresolved results, in 318 negative samples five samples had unresolved results and 313 samples were negative, one unresolved sample was negative in NeuMoDx CT/NG Assay (see table 1). Remarkably, NeuMoDx assay showed more variation in mean (and median) values of ICs between different specimen types. Mean values of 34.0, 37.4, 36.1, 37.0, 34.1 and 40.0 were found for respectively, urine, genital, throat, anal, urethra and eye swabs. Less variation of IC values in different specimen types was seen in Abbott assay.

Conclusions: Overall, the comparison between the NeuMoDx system and Abbott m2000 Real Time CT/NG assay is satisfactory. Discrepancies in results were seen in swab samples collected in guanidium thiocyanate medium. Presence of the guanidium thiocyanate medium in these samples could explain the discrepancies and variation in internal control cycle threshold values, however further investigation is needed for confirmation.

Abstract 4840

Next-generation microscopically-observed drug susceptibility assay (NG-MODS) allows more rapid and precise phenotypic drug-susceptibility testing: preliminary results for Mycobacteroides abscessus

Winston Chiu*1, Caroline Shi-Yan Foo1, Pieter Leyssen1, Emmanuel Andre1,2

1KU Leuven, Leuven, Belgium, 2UZ Leuven University Hospital, Leuven, Belgium

Abstract third-party references: Laboratory of Clinical Bacteriology and Immunology, Department of Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium, Rega Institute, Department of Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium

Background: Among the pathogenic nontuberculous mycobacteria (NTM), Mycobacteroides abscessus is an emerging pathogen carrying an alarming ability to develop drug resistance. Due to the absence of EUCAST or CLSI clinical breakpoints for most antibiotics and the poor analytical performance of current phenotypic drug susceptibility tests for NTM, the treatment of NTM infections remains a major challenge.

Materials/methods: We developed the “next generation microscopically-observed drug susceptibility assay” (NG-MODS), in which high-content digital fluorescent microscopy automatically monitors bacterial growth and death in 96-well plates. This test currently runs in the Caps-It isolator system (Rega Institute, KU Leuven, Belgium). For rapidly growing mycobacteria, IC90 values are computed after 32 hours based on 70 individual measurements performed when exposing the bacteria to different concentrations of each antibiotic. Figure 1A illustrates the dose response growth curves obtained for different concentrations of amikacin while 1B illustrates microscopic images on which these curves are generated.

In this proof-of-concept study, we compared the clinical performance of NG-MODS against the Sensititre™ RAPMYCO (Thermo Fisher, USA) assay using a the M. abscessus subsp. abscessus ATCC 19977 strain and a set of 14 antibiotics (amikacin, amoxicillin-clavulanic acid, cefepime, cefotaxime, ciprofloxacin, clarithromycin, doxycycline, imipenem, linezolid, minocycline, moxifloxacin, tobramycin and trimethoprim-sulfamethoxazole). We used breakpoints available in the scientific literature (Broda et al).

Results: No major discrepancies were observed between the two methods. For 11 antibiotics, we found concordant interpretations of the results (S, I, or R). Cefoxitin, ciprofloxacin and linezolid showed a minor discordance (intermediate versus resistant). The MIC of the latter two differed one dilution with the IC90.

Conclusions: NG-MODS is a novel assay allowing high-throughput, rapid and automated interpretation of DSTs. In this analysis, NG-MODS showed comparable results with RAPMYCO while providing more precise and robust raw information. These encouraging results, which are to be consolidated in a larger comparative study, could ultimately position NG-MODS as a new validated method and support the definition and implementation of EUCAST clinical breakpoints for mycobacteria.
Figure 1: A) Growth curves of *M. abscessus* (ATCC 19977) treated with different concentrations of AMI. B) Images at 12 hours post seeding of growth control, *M. abscessus* (ATCC 19977) treated with 4 μg/mL and 16 μg/mL AMI.

Investigation of the pro-autophagic effect of IL-36α and lipopolysaccharide in THP-1 cell line

Zaid Isam Issa Al-Luhaibi1*, Klara Megyeri1, György Seprényi2

1University of Szeged, Medical Microbiology and Immunobiology, Szeged, Hungary, 2University of Szeged, Department of Anatomy, Histology and Embryology, Szeged, Hungary

Background: Autophagy is an important cellular catabolic process for the removal of damaged organelles, protein aggregates, and intracellular microbes. Autophagy plays important role in various cellular processes and exerts multiple immunological functions. Microbial components and soluble inflammatory mediators regulate the activation level of this antimicrobial cellular process. The lipopolysaccharide (LPS) of Gram-negative bacteria is known to stimulate autophagy. Some cytokines are powerful autophagy inducers, while others act as inhibitors. Interleukin-36alpha (IL-36alpha) is a member of the IL-1 cytokine family. IL-36alpha is highly induced in response to a number of stimuli, and exerts pro-inflammatory effects. The effect of IL-36alpha on autophagy has not yet been fully elucidated. Thus, we investigated the pro-autophagic effect of IL-36α alone or in combination with the TLR4 agonist LPS in THP-1 cells.

Materials/methods: The levels of LC3B-I and LC3B-II proteins were measured by using western blot analysis. The autophagic flux was determined by measuring LC3B-II levels under conditions where autophagosome degradation was blocked by bafilomycin A, a pharmacological inhibitor of lysosomal hydrolase activity and autophagosome-lysosome fusion. The intracellular localization of LC3B autophagic marker protein was determined by using indirect immunofluorescence assay. The LC3B-positive autophagosomes were quantified with the Image J software. Cytoplasmic acidification was detected by acridine orange staining.

Results: The results have shown that the levels of LC3B-II protein were increased in response to IL-36alpha or LPS. THP-1 cultures treated with IL-36alpha and LPS in combination showed significantly higher increases in LC3B-II levels than that of measured in cells incubated in the presence of IL-36alpha or LPS alone. Both IL-36alpha and LPS increased the number of LC3B-positive autophagic vacuoles, the combined treatment was again more efficient that the cytokine or TLR4 agonist alone. Finally, IL-36alpha and LPS stimulated the formation of acidic vesicular organelles.

Conclusions: These results demonstrate that IL-36alpha and LPS synergistically activate autophagy in THP-1 cells, and suggest that IL-36alpha may enhance the innate immune response against certain Gram-negative bacteria.

Novel small-molecule inhibitors of bacterial lipoprotein transport against Enterobacteriaceae

Elena Breidenstein*, Omar Abdulle1, Tim Avis1, Cédric Charrier2, Christopher Coward1, Thomas Duffy1, Gopu Dharmalingam1, Nawaz Khan1, Clive Mason1, Paul Meo1, Nabeetha Nagalingam1, David Powell1

1Summit Therapeutics, Cambridge, United Kingdom, 2IHMA, Monthey, Switzerland

Background: Carbapenem-resistant Enterobacteriaceae (CRE) and Extended-Spectrum β-Lactamase producing Enterobacteriaceae continue to be listed as urgent or serious threats by the World Health Organization and US Centers for Disease Control and Prevention. Through our highly innovative transposon-based technology (Discuva Platform), we identified and are developing DDS-04, a novel new mechanism antibiotic series selective for Enterobacteriaceae.

Materials/methods: High-density transposon mutant libraries were generated in target pathogens. The engineered transposons contain outward facing promoters which can influence gene expression across the entire genome (upregulation, disruption or downregulation). Following compound exposure, NGS of surviving transposon mutants informs on mechanism of action and resistance drivers. Antimicrobial activity, mutation frequencies and kill kinetics were performed according to CLSI guidelines with modifications. In vitro ADME, toxicological, PK and in vivo proof-of-concept studies were performed using standard protocols.

Results: High-throughput screening enabled the identification of a small-molecule hit compound targeting components of the lipoprotein transport complex (LolC/E), a clinically unexploited and essential bacterial molecular target. Further medicinal chemistry established an excellent understanding of the structure-activity relationships that govern permeability and potency against clinically-relevant strains. The DDS-04 series demonstrates potent and specific antimicrobial activity against Enterobacteriaceae including MDR variants (<1 mg/L against MDR E. coli and K. pneumoniae). Importantly, the series is rapidly bactericidal (2-4 h), exhibits a very low mutational frequency and rate against MDR isolates (f10-9-10-10) and no cross-resistance to standard-of-care antibiotics. Optimised compounds from the series display a promising toxicological profile with no haemolytic activity, no mammalian cell cytotoxicity, excellent stability in presence of mouse and human hepatocytes, no mitochondrial toxicity, no monoamine oxidase activity, and no glutathione adduct formation (GSH+S9). PK profile (IV dosing) shows distribution to different sites of infection with significant amounts eliminated unchanged into the urine. Importantly, following single and repeat IV dosing in various murine models of sepsis, pneumonia and urinary tract infections, DDS-04 series compounds demonstrated significant reduction of the bacterial burden compared to the vehicle control.

Conclusions: The discovery of the DDS-04 series, enabled by the Discuva Platform, represents a promising advance in the development of novel drug candidates to treat infections caused by Enterobacteriaceae and warrants continued development.

Visceral leishmaniasis burden in Bologna province, Italy

Giacomo Fornaro*1, Giacomo Bonati2, Elisa Vanino1, Irene Zagh1, Matteo Rinaldi1, Simona Coladonato3, Alessandra Cascavilla1, Michele Bartoletti1, Alessandra Mistral De Pascali4, Stefania Varani1, Luciano Attard2, Pierluigi Viale1

1Alma Mater Studiorum, University of Bologna - Policlinico S. Orsola, Infectious Disease Unit - Department of Medical and Surgical Sciences, Bologna, Italy, 2Alma Mater Studiorum, University of Bologna, Bologna, Italy, 3Alma Mater Studiorum, University of Bologna - Policlinico S. Orsola, Bologna, Italy, 4Alma Mater Studiorum, University of Bologna - Policlinico S. Orsola, Infectious Disease Unit - Department of Medical and Surgical Sciences, Bologna, Italy, 5Policlinico S. Orsola, Unit of Microbiology, Region Reference Centre for Microbiological Emergencies (CREEM), Bologna, Italy

Background: Visceral leishmaniasis (VL) incidence has been growing in Northern Italy. A disease outbreak occurred in Bologna Province between 2012 and 2013. The aim of this study was to describe the recent VL epidemiology in the Bologna Province, Italy.

Materials/methods: We retrospectively enrolled all patients with VL aged >18 years admitted to our centre from January 2016 to January 2019. Clinical, laboratory and microbiological data were collected at BL and for 12 months follow-up (FU). VL was diagnosed in all patients by serology and/or molecular tests. Data about treatment were also collected.

Results: A total of 37 patients (84% male, aged 55.7 ± 17.5) were enrolled. Thirty-four patients (92%) were living in Bologna Province. Nineteen (51.4%) were diagnosed with VL in 2018. Twelve (32%) were immunocompromised. Presenting clinical features were fever (95%, mean body temperature 38.8 ± 0.9 Celsius degrees), splenomegaly (86%) and hepatomegaly (68%). Main laboratory findings were pancytopenia (73%), hyperferritinemia (83%) and hypergammaglobulinemia (62%). Median time between symptoms onset and diagnosis was 29 days (IQR 15-54). At admission, median Sequential Organ Failure Assessment (SOFA) score was 2 (IQR 1-3) and mean Charlson Index (CI) score 2.46 ± 2. Thirty-three out 37 patients were tested by Enzyme-Linked Immunosorbent Assay (EIA) and/or rK39-based Immunochromatographic Test (ICT); corresponding sensitivities were 91% for EIA and 83% for ICT. All patients performed Real Time Polymerase Chain Reaction on peripheral blood or bone marrow specimen, positive in all cases. All patients received liposomal amphotericin B (LAmB): 28 of them (76%) received a 10 mg/Kg single dose, globally well tolerated. At 1-year follow-up 33 patients (86%) were cured, 1 (3%) was lost, 1 (3%, immunocompromised) relapsed and 3 (8%) died during hospitalization. Median age, CI and SOFA score were significantly higher in non-survivors (p <0.001, 0.045, <0.001 respectively). No significative differences were found between cured and relapsed patients.

Conclusions: After 2013, a new VL outbreak raised again in 2018. In this area, VL should be excluded in all subjects presenting with one of the described clinical features. A single-dose of 10mg/kg of LAmB seems effective and safe in our setting.

Colistin-resistant Gram-negative bacteria isolated from humid compartments of high risk hospital units

Giuseppe Fleres*1, Alessia Mirabile1, Mariëtte Lokate1, Natacha Couto1, John W. A. Rossen1, Alexander W. Friedrich1, Silvia García Cobos1,4

1University of Groningen / University Medical Center Groningen Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 2Department of Biomedical and Biotechnological Sciences [BIOMETEC], University of Catania, Catania, Italy, 3University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 4Reference and Research Laboratory on Antimicrobial Resistance and Healthcare-associated infections, National Microbiology Center, Institute of Health Carlos III, Majadahonda, Madrid, Spain

Background: The healthcare water environment including sinks and drainage systems, can be a long-term reservoir of nosocomial pathogens. In this study, we aimed to investigate the presence of Colistin-Resistant Gram-negative bacteria (ColR-GN) in humid compartments of high-risk hospital units in the University Medical Center Groningen (UMCG).

Materials/methods: Samples (n=80) were collected once a month for 5 months (April-August 2019) in the neonatal, pediatric, adult intensive care units (ICUs) and the hematology unit. We sampled fourteen sink drains (neonatal-ICU = 3, pediatric-ICU = 3, adult-ICU = 3, hematology = 5) and two shower drains (hematology= 2) using FLOQSwabs (Copan). Swabs were cultured (100µl) using selective agar-media CHROMID Colistin R (bioMérieux) and the bacteria isolated were identified by MALDI-TOF MS (Bruker). Colistin MICs were determined by broth microdilution following joint EUCAST and CLSI recommendations.

Results: A hundred-thirteen isolates were recovered from selective agar-media and 59 out of them (Enterobacteriaceae= 22, non-fermenting Gram-negative bacteria= 37) were selected for broth microdilution. A total of 38.9% (n=23/59) isolates had a resistant phenotype (MIC ≥ 4mg/L): Klebsiella pneumoniae (n=1, MIC= 64mg/L), Klebsiella aerogenes (n=1, MIC= 32 mg/L), Enterobacter cloacae complex (n=12, MICs 4-64mg/L), Enterobacter bugandensis (n=1, MIC= 32mg/L) Serratia liquefaciens (n=2, MICs= 16mg/L), Morganella morgani (n=1, MIC >64 mg/L) and Stenotrophomonas maltophilia (n=5, MICs 4-64mg/L). ColR-GN were found in all investigated units, Enterobacter spp. being the most abundant bacteria.

Conclusions: The presence of ColR-GN bacteria (mostly Enterobacteriaceae) in sink and shower drains of high-risk hospital units represents a safety concern and a potential threat to immunocompromised patients’ health. Monitoring such environment for antimicrobial resistant bacteria (AMRB) allows to identify reservoirs and to prevent further spread of AMRB. Molecular mechanisms for colistin-resistant will be further investigated by whole-genome sequencing.

Abstract 4847

**Assessing the contribution of sepsis to mortality in Oxfordshire**

Emma Pritchard1,2, A. Sarah Walker1,2, Tim Peto1,2,3, Derrick Crook1,2, Leon Peto1,2,3, Nicola Fawcett1,2,3, Andrew Brent1,3

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2University of Oxford, NIHR Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, Oxford, United Kingdom, 3Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

**Background:** The Sepsis Trust estimates that around 52,000 people in the UK die every year from sepsis. Identifying meaningful patterns across relevant characteristics of deaths may help assess reliability of this estimate.

**Materials/methods:** The study included 9,324 individuals with an inpatient, outpatient, or A&E admission at an Oxford University Hospital who died between 01-Jan-2016 and 30-July-2019, and had any laboratory blood test result or physiological measurement taken in the 7 days prior to death. Sepsis was defined using six published scoring systems [SIRS (1991 and 2001 versions), SOFA, qSOFA, NICE, NEWS] and calculated using individuals’ worst measurements from the 7 days prior to death. Additional indicators of potential sepsis included were prescribed in-hospital antibiotics, primary or secondary infection diagnostic codes, blood culture (any taken or pathogen positive), or fever. Fuzzy C-means clustering was carried out on the proportion of components in each sepsis score an individual met, with binary indicators for the additional factors. This estimates the probability each individual belongs to each cluster, with individuals assigned to the cluster with the largest probability.

**Results:** Four clusters were identified, with characteristics shown in Figure. Cluster-1 (n=2809, 30.1%) contained individuals who were low on all sepsis scores, and all additional factors. The remaining three clusters had high proportions of individuals meeting all sepsis scores and receiving antibiotics, however varied on the other additional factors. Cluster-2 (n=2613, 28.0%) contained few individuals with infection, blood culture, or fever. Cluster-3 (n=1574, 16.9%) had a high proportion with infection diagnostic codes, but a lower proportion of individuals with blood culture or fever. Cluster-4 (n=2328, 25.0%) had the highest proportion of individuals with all additional factors. In cluster-4, 50 individuals received no in-hospital antibiotics (2.2% of cluster-4, 0.5% of study population).

**Conclusions:** Deaths in Oxfordshire broadly fall into 4 different groups using sepsis-associated markers. Cluster-1 compromised individuals whose deaths were clearly not sepsis-related. However, all other clusters had high antibiotic use, and cluster-2 had little infection, suggesting they reflect individuals’ mechanism of dying rather than cases of preventable sepsis. The 50 individuals in cluster-4 who received no in-hospital antibiotics are potentially cases of preventable sepsis.

Abstract 4851

Serotype and susceptibility of invasive pneumococcal disease in adult population

Laura Vinuela1, Cristina García1, Genoveva Santillana1, Paula Bardon1, Rocío Martínez1, Encarnacion Clavijo1, María Victoria García López1*

1Hospital Universitario Virgen de la Victoria, Servicio de Microbiología, Málaga, Spain

Background: Streptococcus pneumoniae is the most frequent etiological agent in community acquired pneumonia (CAP).

The introduction of the new conjugate vaccines has meant an important change in the incidence and epidemiology of invasive pneumococcal disease (IPD).

We have aimed to describe the evolution of circulating serotypes after childhood vaccination, to determine the clinical and epidemiological characteristics of IPD and the pneumococcus sensitivity.

Materials/methods: Retrospective study including 376 isolates from blood culture and cerebral spinal fluid. Results were distributed in two periods according to 13-valent vaccine VNC13: 2003 – 2010 (before vaccination) and 2011 – 2019 (after vaccination). The isolates were serotyped (Instituto de Salud Carlos III) and antimicrobial susceptibility with disk diffusion method was interpreted according to CLSI(2016) and EUCAST(2017) guidelines. The statistical analysis was made by SPSS 22 program.

Results: Out of the 376 studied strains, 89.9% were isolated in blood cultures and 10.1% in CSF. 236 strains were identified before VNC13 and 139 after it. Comparing the two periods, there was a decrease in male proportion (74% vs 62%) and an increase in median age (59 vs 65 years). Out of hospital (93.4%) and emergency department (80.9%) infections remained stable. There were differences in clinical presentation: CAP (60.2% vs 67.1%), septic shock (10.6% vs 7.1%) and meningitis (11.4% vs 12.9%). Mortality was also higher (25% vs 29.5%). The sensitivity to penicillin and cefotaxime for non-meningeal localization was 91.4% vs 97.1% respectively, 78.9% and 95% for meningeal localization. Other susceptibility were: erythromycin (79%), tetracyclines (79.7%), clindamycin (85.1%), levofloxacin (98.7%).

Table. Serotypes prevalence's

</table>

The isolates with less susceptibility were associated to serotypes 8, 19A and 14. The serotypes with decreased sensitivity to penicillin were 19A and 14 (57%). Serotypes associated with increased mortality were 19A (33.3% vs 40%), 23B (100% vs 66.7%), 8 (15.4% vs 30.8%). Serotype 9V (66.7% mortality) has not been isolated after VCN13.

Conclusions: The decrease in the incidence of several adults serotypes indicates that childhood vaccination provides herd immunity. However, 8, 9N and 23B serotypes (not included in VCN13) are still being isolated. These are serotypes associated with high mortality.

Abstract 4852

**Antimicrobial susceptibility of vancomycin-resistant Enterococcus faecium and linezolid-resistant Enterococcus faecium isolated from blood culture in haematological patients: results of multi-centre study in Russia**

Anastasia Fedorova Mironova1, Galina Klyasova1, Irina Frolova1, Svetlana Khrulnova1, Antonina Vetokhina1, Tatjana Kaporskaja1, Irina Molchanova

1National Research Center for Hematology, Moscow, Russian Federation, 2Regional Hospital, Irkutsk, Russian Federation, 3Regional Hospital, Chelyabinsk, Russian Federation

**Background:** The aim of this study was to evaluate the antimicrobial susceptibility of vancomycin-resistant *E. faecium* (VREF) and linezolid-resistant *E. faecium* (LREF), isolated from blood culture in patients with haematological malignancies.

**Materials/methods:** Antimicrobial susceptibility testing was performed in VREF and LREF isolated from blood in hematological patients in six Russian hospitals (2002-2018). Minimum inhibitory concentrations (MICs) were determined by broth microdilution method (CLSI), except daptomycin (Etest, bioMeriéux, France). High-level gentamicin resistance (HLGR) and high-level streptomycin resistance (HLSR) was tested by the agar dilution method (CLSI, 2018). MICs of antibiotics were analyzed using CLSI 2018, MICs of tigecycline by EUCAST, 2018. Vancomycin resistance genes were detected by PCR. Linezolid-resistant isolates were examined for the presence of the mutations in the 23S rRNA gene and ribosomal protein L4 by sequencing. Gfr and optA genes were determined by PCR.

**Results:** Out of 393 *E. faecium* isolated from blood culture 71 (18.1%) were resistant to vancomycin and two (0.5%) were resistant to linezolid (2002-2018). MICs of vancomycin ranged from 128 µg/ml to 2048 µg/ml in VREF isolates, MICs of linezolid were 8 µg/ml and 16 µg/ml in LREF. VREF carried either vanA (66.2%) or vanB (33.8%) genes. All VREF were susceptible to daptomycin (MIC90 2/3 µg/ml) and tigecycline (MIC90 0.064/0.125 µg/ml). Both LREF were susceptible to daptomycin (MIC 0.5 and 1.5 µg/ml), tigecycline (MIC 0.064 and 0.125 µg/ml) and chloramphenicol (MIC 8 and 8 µg/ml). One of them was vanA VREF (vancomycin MIC 1024 µg/ml), and the other was vancomycin-susceptible (vancomycin MIC 0.125 µg/ml). G2576T mutations in 23S rRNA were determined in both linezolid-resistant isolates. The results of susceptibility testing are presented in the table. All vanB VREF were susceptible to teicoplanin. Susceptibility of vanA VREF compared to vanB VREF was significantly lower for HLSR (42.6% vs. 79.2%, p=0.005) and chloramphenicol (74.5% vs. 100%, p=0.006), respectively.

**Conclusions:** Resistance to vancomycin among *E. faecium* was 18.1%. Two (0.5%) *E. faecium* isolates were resistant to linezolid, one of them was vanA VREF, and the other was vancomycin-susceptible. All VREF carried either vanA (66.2%) or vanB (33.8%) genes. VREF isolates carrying vanB had a more favourable susceptibility profile compared to vanA VREF. Daptomycin and tigecycline were active against all VREF and LREF.

**Table. Antimicrobial susceptibility of VREF with vanA and vanB genes**

Abstract 4853

**Clinical dilemma in patients presenting with dengue viral infection**

Memoona Irshad¹, Sher Sethi¹, Kiren Habib¹, Muhammad Zain Mushtaq¹, Faisal Mahmood¹, Bushra Jamil¹

¹Aga Khan University Hospital, Pakistan, Karachi, Pakistan

**Background:** Dengue is a vector borne infection caused by Arbo-virus. Due to its clinical diversity, it had gained more importance in endemic areas. Dengue was first identified in Pakistan in 1994, since then many outbreaks have been reported. There are few case reports of dengue and *Staphylococcus aureus* co-infections despite the fact that both infections individually are common.

**Materials/methods:** We are describing five cases of dengue fever associated with *Staphylococcus aureus* both Methicillin Susceptible (MSSA) and Resistant (MRSA) strain infection in a tertiary care hospital. Clinico-pathological data of every patient is collected and assessed.

**Results:** All patients presented with history of acute fever associated with myalgias. All patients had thrombocytopenia on presentation. Leucocyte counts were variable. All patients had normal hemoglobin and later due to complications (bleeding/DIC), four developed anemia. Five patients had deranged liver function tests, four had deranged renal functions. Two patients developed shock with multi-organ dysfunction. Despite appropriate management all patients were deteriorating thus investigations were sent as per clinical signs and symptoms and *Staphylococcus aureus* infection was identified. All patients were started on vancomycin which was switched to cefazolin in five patients after the finalized culture reports. Source control was done in two patients. Four patients responded well and discharged, one expired and one is still under treatment.

**Conclusions:** In last few years there are cases which reported that dengue can provide a substantial source for secondary bacterial infections. However data is rare and exact mechanism of this co-infection is still not understood. Our study depicts that this viral-bacterial co-infection has poor prognosis leading to longer duration of hospital stay, and increase morbidity. We need to analyze similar studies and case reports in order to identify certain parameters/factors that might help in early identification, management and prognosis of this co-infection. Physicians dealing with dengue infection especially in endemic areas have to be vigilant of this possible yet to be established complication.

Real-life dalbavancin use in acute bacterial skin and skin-structure infections and bone and joint infections: clinical experience at Florence university hospital (Italy)

Nicoletta Di Lauria*, Filippo Bartalesi, Dario Bartolozzi, Michele Cecchi, Paola Corsi, Alessandra Ipponi, Filippo Lagi, Elisabetta Mantengoli, Alessandro Bartoloni

1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 2Careggi University Hospital, Infectious and Tropical Diseases Unit, Florence, Italy, 3Careggi University Hospital, Hospital Pharmacy and Pharmaceutical Policies, Florence, Italy

Background: dalbavancin is a long-acting lipoglycopeptide antibiotic approved for treatment of ABSSSI in adults. Moreover, the unique pharmacokinetic profile, joint to the good penetration into bone and synovial fluid, offers potential opportunities for outpatient parenteral antibiotic therapy (OPAT) in patients with osteomyelitis.

Materials/methods: retrospective analysis of clinical, microbiological and post-use satisfaction data obtained from patients treated with dalbavancin, by the introduction to August 2019, for ABSSSI and bone and joint infections at Careggi University Hospital in Florence (Italy). Patient satisfaction was evaluated using a 3-item questionnaire.

Results: a total of 44 dalbavancin treatments were performed. Twenty-five patients (56.8%) were male, the median age was 62 years (IQR=34-85) and the median Charlson Comorbidity Index (CCI) was 1 (IQR=0-6). The most frequent treated infections were ABSSSI (17, 38.6%). Other infections were osteomyelitis (OM) (12, 27.2%), prosthetic joint infections (PJI) (11, 25%), orthopedic device-related infections (ODRI) (4, 9%). Twenty patients (45.4%) had positive cultures and Staphylococcus spp was the most frequent isolated pathogen (13, 29.5%). Methicillin resistance (MR) phenotype was detected in 11 (85%) of those isolates. The previous failure with other treatments (18, 40.9%) and presence of MRSA risk factors (16, 36.3%) were the main reasons for dalbavancin use. Moreover, 25% of patients had social factors potentially affecting adherence. Clinical cure was reached in 88.2% of ABSSSI, 66.6% of OM, 27.2% of PJI and 75% of ODRI. Recurrence occurred in 36.3% of PJI and in 8.3% of OM. No adverse effects were observed. At the follow-up interview, 90.2% of patients expressed satisfaction with dalbavancin treatment.

Conclusions: In our case series dalbavancin represented a safe and useful outpatient treatment both in ABSSSI and in bone and joint infections. In our setting the off-label use was high (61.2%). The use as second line treatment was frequent due to the potential efficacy against biofilms and the potent activity against MR staphylococci. This last resort use could have affected the overall cure rate. Outpatient management using this long-acting molecule surely represents a real benefit to save healthcare resources and improve quality of life, as clearly showed by the results of the post-treatment satisfaction questionnaire.

Pharmacokinetic variability and target attainment of meropenem in critically ill patients undergoing extracorporeal membrane oxygenation: a matched-cohort analysis

Matthias Gijsen1,2, Erwin Dreesen1, Yves Debaveye3,4, Joost Wauters5,6, Isabel Spriet1,2

1UZ Leuven, Pharmacy Department, Leuven, Belgium, 2Katholieke Universiteit Leuven, Clinical Pharmacology and Pharmacotherapy, Leuven, Belgium, 3Katholieke Universiteit Leuven, Laboratory of Intensive Care Medicine, Leuven, Belgium, 4UZ Leuven, Intensive care unit, Leuven, Belgium, 5UZ Leuven, Medical Intensive Care Unit, Leuven, Belgium, 6Katholieke Universiteit Leuven, Laboratory for Clinical Infectious and Inflammatory Disorders, Leuven, Belgium

Background: Variability in pharmacokinetics and target attainment of meropenem is still unclear in patients undergoing extracorporeal membrane oxygenation (ECMO). Therefore, the aim of this matched-cohort study was to evaluate the effect of ECMO on pharmacokinetic variability and target attainment of meropenem.

Materials/methods: Patients admitted to the intensive care unit (ICU) of the University Hospitals Leuven and simultaneously treated with meropenem and ECMO were eligible. These patients were matched (based on renal function) with non-ECMO ICU patients. The variability in pharmacokinetics was studied using population pharmacokinetic modelling. Probability of target attainment, i.e. 100% fT>MIC and 100% fT>4xMIC, was simulated for different dosing regimens using the MIC breakpoint for Enterobacteriaceae, i.e. 2 mg/L. All modelling and simulation were performed using NONMEM 7.4.

Results: Nine ECMO patients were included, and matched 1:1. A two-compartment model with linear clearance adequately described our data. Creatinine clearance, based on the Cockcroft-Gault formula [CG-CLcr: median [IQR] 108 [76-155] mL/min], explained 27.1% of the interindividual variability (IIV) in meropenem clearance (CLM). Nevertheless, 18.2% and 65.2% of the IIV in CL and Vd remained unexplained. CLM increased with 0.080 L/h per mL/min increase in CG-CLcr. Estimated CLM and Vd were similar between ECMO and non-ECMO patients [CLM: 11.4 vs 11.1 L/h, p=0.899, and Vd: 22.1 vs 24.0 L, p=0.709]. Ten patients (55.6%) maintained a meropenem plasma concentration above 2 mg/L over the full dosing interval (Figure 1a). Only 3 patients (16.7%) maintained a meropenem plasma concentration above 8 mg/L. Simulations of 1000 mg meropenem every eight hours at 30-minute infusions predicted 59.0% and 14.6% of patients attaining the 2 and 8 mg/L targets (N=1000 simulated patients) [Figure 1b]. Extended infusions (4 hours) of 2000 mg meropenem every eight hours and continuous infusion at a daily dose of 3000 mg were required to reach ≥90% of patients maintaining meropenem plasma concentrations above 2 mg/L.

Conclusions: In critically ill patients, target attainment of meropenem was poor under standard dosing but was not found to be influenced by ECMO. ICU patients may benefit from optimised dosing or infusion regimens to improve MIC coverage. Our model may be used to inform meropenem precision dosing.

Reduction of laboratory turnaround time is not the only answer for shorten length of stay at the emergency department

Linda Lind*1,2, Karolina Gullsby1,2, Daniel Scholder3, Eva Röjerås4

1Centre for Research and Development Uppsala University/Region Gävleborg, Gävle, Sweden, 2Gävle Hospital, Department of clinical Microbiology, Gävle, Sweden, 3Roche diagnostics, Stockholm, Sweden, 4Gävle Hospital, emergency department, Gävle, Sweden

Background: During the influenza season the emergency departments (ED) gets overcrowded and long waiting times are a big burden for the hospitals. At Gävle Hospital, Sweden, 24/7 use of rapid PCR testing for influenza was introduced in December 2016. Despite the introduction of the rapid PCR, ED experienced long response times from the microbiological laboratory.

The aim of the study was to investigate how the introduction of rapid PCR testing for influenza reduced the time spent at the ED and what other factors that played a role.

Materials/methods: Workflow optimization by using LEAN and A3 methodologies was done at the ED. The turnaround time was measured from admission of patients with influenza like illness to the ED until the patient was discharged from the ED. The goal is that no patients need to spend more than four hours in the ED before admission.

Some of the optimizations factors were: training off staff, flu sample was taken earlier in the process, a checklist was ceated for nurses so they could take the samples without the doctor’s prescription and the sampling instructions were more easily accessible.

Measurement was done before and after optimization of the workflow. The impact of a new even quicker rapid PCR test for influenza was also added to see if it would shorten the length of stay at the ED.

Results: The average turnaround time before the optimization of workflow were seven hours and only 8 percent of the patients were discharged from the ED within four hours. After implementation of the new workflow and onset of the new rapid PCR the turnaround time decreased to 5.3 hours and 33 percent of the patient were discharged from the ED within four hours.

Conclusions: Reduction of laboratory turnaround time is not the only answer for shorten length of stay at the Emergency Department. An interaction between lab and ER is the best way to solve the burden at the ED.

Current diagnosis, management and control strategies for Clostridioides difficile infection in Europe

Maria Adriana Cataldo*, Guido Granata¹, Nicola Petrosillo¹, Kerrie Davies²

¹National Institute for Infectious Diseases "L. Spallanzani", Roma, Italy, ²Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom

Abstract third-party references: On behalf of the COMBACTE-CDI consortium.

Background: Diagnostic and management strategies to face C. difficile infection (CDI) are rapidly evolving over the years. The aim of our study was to show the compliance to the current CDI diagnosis, notification and management guidelines in Europe, as assessed by a survey.

Materials/methods: In 2018, in the framework of the European COMBACTE-CDI project, a questionnaire was sent to hospitals, long-term care facilities (LTCFs), residential care facilities, general practitioners (GPs) and laboratories from 12 different European countries. Questions in the survey focused on the awareness of and compliance with national/local CDI testing and CDI notification policies/guidelines and on strategies adopted to avoid CDI spread.

Results: One hundred fifty-five European centres/facilities participated in the survey. Overall, 104/155 (67%) of the participants were aware of national CDI testing policy guidelines, reported awareness was lower in the Netherlands (33%), Italy (38%) and Greece (50%). The overall percentage of compliance with national testing guidelines was 104/155 (67%) whereas it was markedly lower among LTCFs (1/4, 25%) and GPs (3/39, 8%).

Regarding CDI notification, overall 111/155 (72%) of the participants reported that they notified cases of CDI regularly; 84/107 (79%) and 15/36 (42%) of hospitals and GPs, respectively, declared notification of CDI cases. Where CDI was suspected, surveyed hospitals reported adoption of contact precautions “always” and “often” in 41/107 (38%) and 22/107 (21%) of cases, respectively. Of note, 5/107 (5%) reported never adopting contact precautions in cases of suspected CDI.

Where CDI was confirmed, 39/39 (100%) of the residential care facilities reported always adopting contact precautions. Among hospitals, 80/107 (75%) and 11/107 (10%) “always” and “often” adopted contact precautions.

Conclusions: Our survey shows that compliance with CDI testing guidelines and notification policies varies according to different settings and geographical areas. Importantly, an alarmingly low rate of compliance with contact precautions for patients with suspected CDI has been reported. Our results highlight possible areas for improvement in guideline communications.

Abstract 4861

**Faecal microbiota transplantation via lyophilised capsules in primary episodes of Clostridioides difficile infection: preliminary results from a randomised clinical trial (EudraCT 2017-003147-38)**

Emilio Bouza*, Maria Olmedo Samperio1, Martha Kestler Hernandez1, Silvia Noemi Vazquez Cuesta1, Sara Rodriguez-Fernandez1, Laura Villar Gomara1, Luis Alcalá1, Mercedes Marin1, Patricia Muñoz1, Elena Reigadas Ramirez1

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

**Background:** Fecal microbiota transplant (FMT) is highly effective for treating multiple recurrent Clostridioides difficile infection (CDI) with an efficacy rate of nearly 90%. There is few data on the efficacy and safety of FMT in the treatment of primary CDI episodes. After an initial episode, risk for recurrence (R-CDI) is high, patients have important gut dysbiosis and oral vancomycin alters the gut microbiome further. FMT administered in primary episodes could help restore the microbiome and thus reduce R-CDI. The objective of this study was precisely to evaluate the efficacy and safety of FMT versus a standard 10 day course of vancomycin for primary CDI episodes.

**Materials/methods:** A randomized clinical trial in which patients were enrolled at a 1:1 ratio to a FMT lyophilized capsule regimen (single dose of 4 capsules) that includes preparatory antibiotic treatment (vancomycin 125mg/6 hours for 5 or 10 days depending on therapeutic response) or treatment only with standard vancomycin 125mg/6 hours 10 days. The primary end point was the proportion of patients without R-CDI at 8 weeks after treatment.

**Results:** From July 2018 (ongoing study) we have enrolled 32 patients (1 patient discontinued trial prior to receiving FMT). Patients’ median age was 76.5 years [IQR 59.0-84.8] and 71.9% were female. Seventeen patients received the standard 10 day vancomycin course and 15 received lyophilized FMT capsules and preparatory vancomycin (78.6% received a 5-day course; 21.4% a 10-day course). Twenty-nine patients completed the follow-up period, prevention of R-CDI was achieved in 85.7% in the FMT capsule group and in 80.0% in the standard vancomycin alone group (p=1.000). Adverse events were 35.7% for the FMT capsule group vs 20.0% in the standard vancomycin alone group (p=0.427), no serious events were related to the CDI treatments.

**Conclusions:** Our results show that so far, among adults with primary CDI, FMT via oral lyophilized capsules was not inferior to treatment with standard vancomycin 10 day course alone for preventing R-CDI over 8 weeks. Treatment with FMT lyophilized oral capsules may be an effective approach to treating primary CDI, enabling for a shorter vancomycin course of 5 days and restoring the microbiome.

Abstract 4863

Microbiome characterisation of patients with *Clostridioides difficile* infection and colonised patients

Silvia Noemi Vazquez Cuesta*, Nuria Lozano1, Laura Villar Gomara1, Luis Alcalá1, Mercedes Marin1, Patricia Muñoz1, Emilio Bouza1, Elena Reigadas Ramirez1

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

Abstract third-party references: On behalf of HGUGM Microbiome Project

**Background:** *Clostridioides difficile* is the main cause of nosocomial diarrhea, although distinction between colonization and infection is sometimes difficult. Patient stratification according to risk for recurrence (R-CDI) and for those evolving to severe complicated CDI is necessary to plan the proper management, however, clinical criteria is insufficient. The objective of our study was to characterize the microbiome profile of healthy, CDI and colonized patients, in order to establish possible differences that could be of use in CDI identification and risk stratification.

**Materials/methods:** Prospective study (Jan 2019-ongoing), patients positive for *C. difficile* and healthy controls were enrolled. Clinical data and fecal samples were collected. The hypervariable V4 region of the 16S rRNA gene was sequenced on an Illumina Miseq platform. Sequenced data preprocessing, OTU clustering and taxonomic classification were done using MOTHUR software, RDP and SILVA database. Alpha/Beta diversity analysis and statistical analysis were conducted by MOTHUR, QIIME 2 and R.

**Results:** A total of 244 subjects were enrolled, 167 (n=192 samples) were analyzed and classified as follows: Healthy (54), CDI (123) and Colonized (15). Alpha-diversity and richness were significantly higher in the healthy group versus CDI and colonized (p<0.001; both). Beta-diversity was significantly different between all groups (p<0.001), as well as the abundance of specific microorganism groups (Figure). Patients with previous CDI had lower richness (p=0.036) as well as those with R-CDI (p=0.019). Beta-diversity was significantly different in R-CDI vs first episode (p=0.0079) and in those with and without previous CDI episodes (p=0.009). Severe-complicated episodes had lower abundance of *Actinomyces*, *Bifidobacterium*, *Bacteroides*, *Prevotella*, *Blautia*, *Streptococcus*, *Clostridium XIVA/b*, *Fusobacterium* and *Proteus* (p<0.001). Patients that presented R-CDI had in their first episode sample, higher abundance of *Fusobacteria* and lower levels of *Collinsella* (p=0.039), *Prevotella* (p=0.0013), *Alistipes* (p=0.022), *Lactobacillus* (p=0.022), *Blautia* (p=0.022), *Clostridium XIVA* (p=0.0014), *Roseburia* (p=0.0037), and *Veillonella* (p=0.039).

**Conclusions:** We found significant differences in the microbiome profile between CDI cases and *C. difficile* asymptomatic colonization. Prior CDI episodes and R-CDI episodes had a cumulative impact in the microbiota, traduced in less alpha-diversity and richness. We identified several groups of microorganisms that may serve as microbiological markers for CDI severity and prediction of R-CDI.

Abstract 4865

**Comparative protein binding in vitro and in vivo: quantitative insights into binding dynamics by pharmacometrics**

Sebastian Wicha¹, Beatrix Wulkersdorfer², Elizaveta Kurdina², Peter Matzneller², Valentín Al Jalali², Matthias Vossen², Sonja Riesenhuber², Edith Lackner², Christoph Dorn³, Frieder Kees¹, Markus Zeitlinger²

¹University of Hamburg, Dept. of Clinical Pharmacy, Institute of Pharmacy, Hamburg, Germany, ²Medical University of Vienna, Dept. of Clinical Pharmacology, Wien, Austria, ³University of Regensburg, Institute of Pharmacy, Regensburg, Germany

**Background:** Ceftriaxone (CRO), a third-generation cephalosporin, is a commonly used antibiotic, in particular in patients with serious infections. For CRO, protein binding (PB) is high but non-linear and thus a critical determinant for the antibacterial effect. A recent study identified fundamental differences between protein binding determined by *in vitro* methods (ultrafiltration) and *in vivo* venous microdialysis. The objective of the present study was to quantify the different protein binding by means of pharmacometric modelling.

**Materials/methods:** A single i.v. infusion 2 g CRO was administered to six healthy male volunteers over 30 minutes. Antibiotic plasma concentrations as well as unbound CRO by means of ultrafiltration (*in vitro*) as well as venous microdialysis (*in vivo*) were measured for up to 6 hours after drug administration. Non-linear mixed effects modelling in NONMEM® 7.4 was used to characterize the protein binding quantitatively.

**Results:** A two-compartment model adequately described the total concentrations of CRO. Protein binding was best characterized by a non-linear, saturable protein binding with significant difference between *in vitro* and *in vivo*. The dissociation constants (Kd) for the albumin-CRO complex was in median [CI95%] of 44.95 µM (38.5-52.5) *in vitro* vs. 30.1 µM (27.7-33.1) *in vivo*. Moreover, the estimated number of binding sites per albumin molecule was 0.94 (0.92-1.03) *in vitro* vs. solely 0.62 (0.60-0.64) *in vivo* in vivo. In addition, a time-delay for the formation of the CRO-albumin complex of approx. 15 min was quantifiable. Median fraction unbound (range) was 0.18 (0.16-0.21) *in vitro* vs. 0.37 (0.34-0.42) *in vivo* in the distribution phase at 0.5 h or 0.083 (0.075-0.093) *in vitro* vs. 0.090 (0.080-0.101) *in vivo* at 6 h.

**Conclusions:** Significantly different protein binding was observed in *in vitro* ultrafiltration vs. *in vivo* intravasal microdialysis with a tendency to over-estimate the protein binding in *in vitro*, in particular in the distribution phase. The pharmacometric analysis revealed that ultrafiltration did not capture the highly dynamic processes of protein binding, while with *in vivo* microdialysis the onset of the formation of the albumin-CRO complex was quantifiable. The dynamics of protein binding should be considered in PK/PD studies of antibiotics to derive accurate therapeutic breakpoints.

**Figure:** Visual predictive check of the developed pharmacometric model for the matrices plasma (left), ultrafiltration (middle) and microdialysate (right). Observed data (circles) with 10th, 50th and 90th percentile of observed (black) and model-predicted data (red) with confidence intervals of the prediction (shaded areas).

### Abstract 4866

**Invasive aspergillosis and influenza virus infection: an accidental relationship?**

Marina Machado*1,2, Helmuth Guillén Zabala1, Maricela Valerio Minero1, Alicia Galar Recalde1,2, Martha Kestler Hernandez1,2, Pilar Catalán1, Belén Padilla1, Jose Peral1, Elena Reigadas Ramirez2, Jesus Guinea Ortega1,2, Pilar Escribano1, Roberto Alonso1, Emilio Bouza Santiago1,2,4, Patricia Muñoz1,2,4

1Gregorio Marañón Hospital, Clinical Microbiology and Infectious Diseases, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3Gregorio Marañón Hospital, Intensive Care Unit, Madrid, Spain, 4CIBERES, Madrid, Spain

**Background:** Reports suggesting that 19% of patients with influenza virus infection (FLU) requiring admission to an ICU developed invasive aspergillosis (IA), may provide a biased vision of the problem. Data matching whole populations with either IA or FLU are required.

**Objective:** To analyse the frequency of IA in the whole population with FLU and the impact of FLU in the whole series of IA in our institution.

**Materials/methods:** In our centre, a multidisciplinary collaboration group in mycology (COMIC) is on place since 2011, which facilitates the diagnosis and treatment of all IA and maintains a prospective registry. The registry of patients with FLU diagnosed by GeneXpert is also available during the study period (Oct-2016 to July-2019).

**Results:** IA complicated 9/2911 cases of FLU diagnosed in our institution in the 3-years study period (0.31%), since GeneXpert test is available. FLU was one of the underlying comorbidities in 9/53 patients with IA (16.9%) (Table 1); Flu-A predominated (77.8%). Median age was 70 years (IQR 61.5-79.5). Regarding the 9 cases, all of them were classified as probable pulmonary IA. Previous immunosuppression was present in 7/9 and only one patient had no other risk factor than FLU for developing IA. Underlying conditions included COPD 7 (77.8%), heart disease 6 (66.7%), diabetes mellitus 4 (44.4%), solid-tumour 4 (44.4%), cirrhosis 3 (33.3%), haemodialysis 1 (11.1%), AIDS 1 (11.1%). Two patients had suprarenal insufficiency on corticosteroid treatment. None of the patients had either neutropenia (<500/mm³), haematological malignancy or were SOT recipients. Regarding microbiology results, 6 patients had *Aspergillus fumigatus*, 1 *Aspergillus nidulans* and 2 mixed-infection [1 *A. fumigatus* + *Aspergillus lentulus* and 1 *A. fumigatus* + *Aspergillus ustus*]. Calcofluor was positive in 8/8 patients. Non-culture based tests were positive in 88.9% [serum GM: 5/8, BAL GM: 2/3 and serum 1,3-β-d-glucan: 6/6].

**Conclusions:** Invasive aspergillosis is uncommon in a large population with Influenza, 0.31% in our series. However, influenza and its severity can condition the development of invasive aspergillosis when there is a predisposing condition in the patient. Influenza and aspergillosis confection can be rapidly progressive and life threatening.

Abstract 4867

**Stigma in MDRO carriers exposed to isolation precautions: an exploratory quantitative questionnaire study**

Roos Wijnakker*1, Merel Lambregts1, Babette Rump2, Karin Ellen Veldkamp3, Ria Reis4, Leo G. Visser1, Mark G.J. De Boer1

1Leiden University Medical Center (LUMC), Infectious diseases, Leiden, Netherlands, 2National Institute for Public Health and Environment, Bilthoven, Netherlands, 3Leiden University Medical Center (LUMC), Microbiology, Leiden, Netherlands, 4Leiden University Medical Center (LUMC), Medical Anthropology, Leiden, Netherlands

**Background:** Isolation precautions are applied to control the risk of transmission of multi-drug resistant organisms (MDROs). These precautions have been associated with adverse effects, such as perceiving barriers in access to healthcare and feelings of anxiety and depression. This study aims to quantify the experience of stigma among carriers of MDROs, evaluate its association with mental health and experienced quality of care.

**Materials/methods:** A quantitative questionnaire study was performed in a population of MDRO carriers, exposed to ≥ 3 days of contact precautions during hospitalization. Due to the very low frequency of self-reported stigma at interim analysis, the study was halted at 41 inclusions. Items derived from the Consumer Quality Index questionnaire (CQI) were used to assess participants perception of care. Stigma scores were calculated using the recently developed modified Berger Stigma Scale for MRSA. Mental health was measured with the five-item RAND Mental Health Inventory. The Spearman rank correlation test was used to assess the association between stigma and mental health and between stigma and CQI.

**Results:** Of the 41 included individual patients, 31 (75.6%) completed both questionnaires. The experienced quality of care by the participants was good according to the CQI score. Receiving proper explanation from healthcare workers (HCWs) about MDRO was self-reported by only 24.4% of the participants. Stigma was reported in 1/31 (3.2%). Poor mental health was observed in 3/31 (9.7%) of participants. There was no clear correlation between stigma and mental health. (Figure 1)

**Conclusions:** In this prospective quantitative questionnaire study, MDRO carriers exposed to at least three days of contact isolation precautions did not report stigma associated with this setting. This contrasts with a recent study that investigated MRSA associated stigma. However, for MRSA isolation more strict isolation protocols are in place, and the psychological impact may be of a different magnitude due to yet unknown reasons. Most probably, adequate quality of care, education of HCWs and public awareness about MDROs is important to avoid stigma.

**Figure 1 MDRO Alerts**

Methicillin-resistant Staphylococcus aureus bacteraemia: clinical-epidemiological characteristics and evolution of oxacillin resistance in 17 years

Laura Vinuela1, Genoveva Santillana1, Rocío Martinez1, Paula Bardon1, Cristina García1, Encarnacion Clavijo1, María Victoria García López*1

1Hospital Universitario Virgen de la Victoria, Servicio de Microbiología, Málaga, Spain

Background: S. aureus bacteremias are one of the main problems in infectious pathology. The variability of S. aureus, the rapid adaptive response to changes in the environment, and its acquisition of antibiotic resistance have made it a habitual resident of the hospital habitat.

Our aim is to know the clinical-epidemiological factors of MRSA bacteremias and the evolution of oxacillin resistance in the last 17 years.

Materials/methods: Retrospective study of S. aureus bacteremias from January 2001 to May 2018. Blood cultures were processed by the BACTEC-FX system [BectonDickinson®]. The identification and sensitivity study was performed with the automated system MicroScan-Walkaway [Siemens®], Vitek 2® [Biomérieux] and E-Test. The statistical study was made by SPSS 22.0.

Results: 935 patients presented bacteremias due to S. aureus, 176 (18.8%) were MRSA. 60.2% were males with average age of 64.1 (14-91 years). 58.5% were in-hospital bacteremias with average admission of 37.3 days (40% >30 days and 25% were admitted in the previous 6 months).

40.3% came from medical services, 25% from the emergency room, 20.5% from ICU. 88.6% presented monomicrobial bacteremia. The most frequent medical profile were: primary bacteremia (37.7%), sepsis and/or septic shock (25.4%), catheter-associated bacteremia (12.3%), pneumonia (7.5%) and endocarditis (1.8%).

Crude mortality was 39.8% in MRSA compared to 31.4% in MSSA (p<0.05). 83.1% of the exitus in MRSA had a MIC to vancomycin <1.5.

The main causes of mortality were: primary bacteremia (35.4%); septic shock and/or sepsis (33.3%) and catheter-associated bacteremias <5%.

Regarding sensitivity: 4.3% were sensitive to penicillin, 70.9% to gentamicin and 32% to tobramycin, 35.8% to erythromycin and 61.4% to clindamycin, 9.7% to ciprofloxacin and 97.7% sensitive to linezolid. Vancomycin sensitivity was 99.4%, 17.1% with MIC>1.5 (10.8% MIC 2 and 6.3% MIC 4).

18.8% were resistant to cloxacillin (14.28% in 2001 and 16.7% in 2016, with a peak in 2013 (31%)).

Conclusions: The bacteremia caused by MRSA in our country is more frequent in men with an average age of 64.1 years old, intrahospital and from medical services.

Cloxacillin resistance has decreased in recent years, peaking in 2013 (31%), currently reaching values similar to 2001 [2001: 14.3%; 2017: 15.3%].

In spite of the high mortality (39.8%), we have not found a relationship between it and vancomycin MIC>1.5.

Abstract 4870

An antimicrobial stewardship program in emergency department: clinical and epidemiological study of sepsis due to multidrug-resistant organism

Giulia Marini1, Sergio Mezzadri1, Romina Corsini2, Nicoletta Riva1, Marco Massari1, Giuseppe Riusello3, Paolo Giorgi Rossi4, Marta Ottone4, Carlotta Bonilauri5, Davide Maria Francesco Lucchesi2, Anna Maria Ferrari5

1Azienda USL – IRCCS di Reggio Emilia, Infectious Disease Unit, Reggio Emilia, Italy, 2Azienda USL – IRCCS di Reggio Emilia, Reggio Emilia, Italy, 3Azienda USL – IRCCS di Reggio Emilia, Microbiology Unit, Reggio Emilia, Italy, 4Azienda USL – IRCCS di Reggio Emilia, Epidemiology Unit, Reggio Emilia, Italy, 5Azienda USL – IRCCS di Reggio Emilia, Emergency Department Unit, Reggio Emilia, Italy

Background: In the last decades the prevalence of antimicrobial resistance (AMR) in Europe represent a serious threat to patient safety. In some countries is necessary to adequate empiric antibiotic treatment for sepsis to cover infection due to MDRO. For this reason we promote a sepsis performance improvement program in the Emergency Department (ED) through the development of a surveillance system for local epidemiology in order to guide a three years antimicrobial stewardship (AMS) program in ED.

Materials/methods: This was an observational, retrospective study about patients admitted to the ED of the IRCSS ASMN, Reggio Emilia (Italy), with diagnosis of sepsis from January 2019 to June 2019. Demographics, clinical and laboratory data, risk factors for MDRO, microbiological findings, infectious source, adherence to the Surviving Sepsis Campaign (SSC) bundle, disease severity score, empiric antibiotic therapy were recorded.

Results: During the study period there were 50,045 general ED attendances. A total of 580 patients with sepsis were enrolled (50.9% males, median age was 81 (IQR,71-88). The most frequent source of infection were lung (32%) and urinary tract (28.3%). Blood cultures were performed in 493 patients (85.7%): 121 in ED (20.9%) and 327 (64.8%) in ward within 48 hours of admission. There was a total of 222 microbiological isolation from 192 patients, 20.72% of them were MDRO. The most prevalent MDRO were ESBL+ Enterobacteriaceae (65.2%). 147 patients (25%) receive antibiotics in ED (71% was appropriate to antibiogram) and 38 patients complete SCC bundle. 63.8% of patients had at least one risk factor for MDR, the most represented are: hospitalization in the previous 6 months (44.4%), antibiotic therapy in the last 90 days (28%) and medical devices (21.5%). 192 patients have qSOFA ≥2, 353 NEWS-2 ≥ 5 and 449 SOFA ≥ 2. Overall, 159 patients (27.4%) died within 30 days and 215 (37%) within 90 days of ED admission.

Conclusions: This epidemiological study shows that the prevalence of MDRO in sepsis admitted in ED are high (20%), so we decided to start an antimicrobial stewardship program with ED physicians to help them to choose the best empiric antibiotics therapy in patients with specific risk factors.

Resistance to ceftolozane-tazobactam and ceftazidime-avibactam in extensively drug-resistant (XDR) and multidrug-resistant (MDR) Pseudomonas aeruginosa: comparing antimicrobial activity, associated risk factors and clinical outcomes

Marianna Meschiari*, Kaleci Shaniko, Vincenzo Bianco, Mario Sarti, Gabriella Orlando, Andrea Bedini, Cristina Mussini

1Infectious Disease Clinic, Azienda Ospedaliero-Universitaria di Modena, University of Modena and Reggio Emilia, Modena, Italy, 2University of Modena, Modena, Italy, 3Federico II University, Napoli, Italy, 4Clinical Microbiology Laboratory, University Hospital of Modena, Modena, Italy

Background: Real-world experiences designed to evaluate risk factors associated with resistance to the two-novel beta-lactam/beta-lactamase inhibitor combinations (BLBLICs) and clinical outcomes are lacking.

Materials/methods: A retrospective case-control study was conducted at the Modena University Hospital from December 2017 to January 2019 including all consecutive patients with an MDR PA isolates. To obtain relative risks (RRs) associated with resistance to Ceftolozane-tazobactam (C/T), resistance to ceftazidime-avibactam (CZA) and combined resistance to new BLBLIC, univariate and multivariate analyses were performed using log-binomial regressions.

Results: During the study period 117 PA isolates were collected: colistin was susceptible in 87.1% followed by amikacin 78.6%, CZA 64.1% and C/T 63.2%. Cefepime (FEP) retained susceptibility in 38.3% followed by ceftazidime (CAZ) 29.3%, imipenem 26.3%, piperacillin/tazobactam 23.3% and meropenem (MEM) 19.8%. Among C/T-resistant isolates, 34.9% was CZA susceptible, whereas 33.3% of CZA-resistant isolates were susceptible to C/T. The result of multivariate showed the risk factors significantly associated with resistance to C/T were Charlson score (risk ratio [RR]=1.71) previous MEM (RR =1.18), the Central Vascular Catheters (CVC) (RR=1.76), Orotracheal Intubation (IOT) (RR=1.40), MEM use (RR=1.42) and FEP (RR=3.65). The multivariate log-binomial regression for the risk factors associated with resistance to CZA show that the CVC (RR=1.71) IOT (RR =1.52), CAZ (RR =8.95; 95% CI, 1.28-62.55, p=0.027) and FEP (RR=2.77) exposure were the main risk factors for resistance. Risk factors significantly associated with combined resistance to C/T and CZA were Charlson score (RR]=1.73), MEM (RR =1.11), CVC (RR=1.55), IOT (RR=1.18) and FEP (RR=16.44). Lastly, concerning clinical outcomes, patients with combined resistance to CZA-C/T showed a longer length of hospitalization, day±Std 77.8±54.3 vs 45.9±32.1, (P=0.001) and a significant higher mortality (62.96% vs 38.33%; P= 0.033).

Conclusions: Taking into account the different C/T/CZA residual susceptibility combination, both agents may be considered complementary therapeutic resources for PA hard-to-treat infection, especially lifesaving among isolates resistant to all traditional antipseudomonal beta-lactams. Considering the role of previous carbapenems exposure as the main risk factor for resistance, we urgently need for further efforts in reinforcing antimicrobial stewardship targeted to balance the correct C/T and CZA place in therapy.

Evaluation of two lateral-flow assays with galactomannan in BAL fluids for the detection of invasive pulmonary aspergillosis: a retrospective two-centre study

Ulrike Scharrmann¹, Hedda-Luise Verhasselt¹, Lisa Kirchhoff¹, Peter-Michael Rath¹, Jörg Steinmann², Katharina Ziegler*²

¹Essen, Institute of Medical Microbiology, Essen, Germany, ²Nuremberg Clinic, Institute of Clinical Hygiene, Medical Microbiology and Clinical Infectiology, Nürnberg, Germany

Background: Investigation of Galactomannan (GM) in respiratory samples is used as a diagnostic tool to detect invasive pulmonary aspergillosis (IPA). In this study, two Lateral Flow Assays, OLM Aspergillus Lateral Flow Device (LFD) and IMMY sôna Aspergillus Galactomannan Lateral Flow Assay (LFA), were evaluated against the GM enzyme immunoassay (ELISA) at two tertiary hospitals in Germany.

Materials/methods: A total of 200 bronchoalveolar lavage samples (BAL) from patients with suspicion of invasive aspergillosis from two tertiary hospitals were analysed retrospectively at two sites (100 samples at Paracelsus Medical University, Nuremberg and 100 samples at the University Hospital Essen). LFD [OLM Diagnostics, Newcastle Upon Tyne, United Kingdom] and LFA [IMMY, Oklahoma, USA] were evaluated against GM ELISA [Platelia, Bio-Rad Laboratories, Marnes-la-Coquette, France]. All tests were performed according to the manufacturers’ instructions. Immunochromatographic tests were read by cube-readers. For agreement analysis GM ranges were defined as follows: GM index < 0.5 (n=35), 0.5 - 1.0 (n=29), > 1.0 – 3.0 (n=51) and > 3.0 (n=85).

Results: The agreement of LFD and LFA with negative GM values in all BAL was 74 % and 51 %, respectively. The concordance between low positive GM values (0.5 to 1.0 and > 1.0 to 3.0) correlated in 26 % and 39 % with LFD results and 83 % and 96 % with LFA results, respectively. BAL with high GM values (> 3.0) had an overall agreement of 81 % with LFD results and 100 % with LFA results. The overall agreement between GM and LFD was 61 % and LFA was 88 %. The correlation between GM and LFA was r = 0.8.

Conclusions: LFA seems to be the most promising immunochromatographic test exhibiting the best agreement with positive GM values. LFA is recommended as an alternative for the GM ELISA as a diagnostic tool for the detection of an IPA.

Abstract 4876

**Nosocomial bloodstream infection rates: exploration of a quality indicator for infection prevention**

Bart Laan*1, Suzanne E. Geerlings1, Wil De Rond2, Ingrid J. B. Spijkerman1

1Amsterdam UMC, University of Amsterdam, Internal Medicine, Infectious Diseases, Amsterdam, Netherlands, 2Amsterdam UMC, University of Amsterdam, Medical Microbiology, Amsterdam, Netherlands

**Background:** Outcome indicators for the quality of infection prevention in hospitals are scarce and time consuming to collect. In the Netherlands, the proposed rate of bloodstream infections by highly resistant microorganisms (HRMO) is so low that it has no use as a tool for focussing interventions and comparison between hospitals and wards. Therefore, we monitored nosocomial bloodstream infections rates during a 3-year surveillance period and evaluated its use as an indicator for infection prevention.

**Materials/methods:** Between January 2016 and January 2019, we conducted an observational, prospective surveillance in a tertiary teaching university hospital. We collected data on positive blood cultures in patients admitted to the hospital for more than two days from the Laboratory of Bacteriology. Data on source of BSI, ward, specialism and other patient characteristics were collected from electronic medical records. Rates of BSI were calculated as number of BSI per 1000 patient days.

**Results:** The overall prevalence of nosocomial BSI was 2.33 per 1000 patient days. The rates varied from 2.04 in 2016, 2.14 in 2017, and 2.92 nosocomial BSI in 2018. The increased rate in 2018 is probably due to a quality improvement project to increase adherence of taken blood cultures before starting antimicrobial therapy. The most common sources of BSI were (central) line-associated bloodstream infections (35.9%) and abdominal infections (18.2%). Coagulase-negative staphylococci (27.4%) and Enterobacteriaceae (23.7%) were the most commonly pathogen. The rate of HRMO was stable over time (5.1%).

Rates of nosocomial BSI varied considerably between wards and specialisms. In addition, the distribution between sources of nosocomial BSI is variable for different wards. Time trends of nosocomial BSI were used for monitoring and feedback per ward. The department of Infection Prevention spent 2.5 hours per week on data collection and cleaning.

**Conclusions:** Rate of nosocomial BSI can be used to monitor the performance of wards over time. In our hospital, nosocomial BSI is a solid, quick, inexpensive, and easy to perform outcome indicator for infection prevention. Sub-analysis of source of BSI per ward can evaluate focus interventions to decrease nosocomial BSI rates.

Achromobacter identification using nrdA gene phylogeny and MALDI-TOF MS

Marilyne Rumigny1, Françoise Allard1, Valérie Collin1, Christophe Meunier1, Delphine Giraud1, Valerie Monnin1, Victoria Girard1, Fabien Javerliat1

1bioMérieux, La Balme-les-Grottes, France

Background: The genus Achromobacter was first described in 1981 and contains today 20 species. Species from this genus are considered as emerging nosocomial pathogens and as new species are described frequently, there is a growing need of robust identification systems with evolving databases such as MALDI/TOF. In order to update those databases, the characterization of the new species using the nrdA gene is necessary as 16S RNA sequencing is not discriminant enough. In this study, we describe the use of nrdA gene phylogeny combined with MALDI TOF to identify Achromobacter species.

Materials/methods: A set of 110 strains representing 18 species of Achromobacter, from the bioMerieux collection, including type strains of new species and strains originally identified as A.denitrificans by phenotypic methods were sequenced on a polymorphic region of 760 bp of the nrdA gene. The phylogenetic trees were constructed using UPGMA and compared to dendrograms obtained using spectra acquired on the Vitek®MS platform in the 3000 to 17000 da mass range.

Results: The analysis showed that 90.9% of the strains were identified to the genus Achromobacter. Among those 90.9%, 44.36% were identified as the expected species and 44.54% as a different one. 6.36% of the strains could not be classified at the species level and 2.74% have been reclassified in other genera (Bordetella and Cupriavidus). Concerning the historical species: 39 strains originally A.denitrificans, 5 strains A.xylosoxidans and 8 strains A.piechaudii were reclassify. The Vitek®MS spectra dendrograms were in accordance with the sequencing data.

Conclusions: The nrdA gene phylogeny and Vitek®MS spectra allow a good discrimination of Achromobacter species including species that were not discriminated by phenotypic techniques. We are waiting for strains from the two recently described species A.sediminum and A.aloeverae to complete the analysis. This study shows that phylogeny combined to MALDI TOF is necessary to characterize species of the genus Achromobacter and to allow the identification systems to be more accurate.

Investigation of electric signaling in bacterial biofilms with the Specialised Thin Agar Method (STAM)

Julia Assmann*, Silvio Bürge, Christoph Schaudinn, Birgit Walther

1Robert Koch Institute, Advanced Light and Electron Microscopy (ZBS 4), Berlin, Germany

Abstract third-party references: Federal Ministry of Education and Research (Grant ID 01KI1803), German Research Platform for Zoonoses

Background: Prevention or even eradication of bacterial biofilms in medical settings and devices is a continuing issue worldwide. Besides quorum sensing mediated by small signal molecules, Bacillus subtilis also communicate via electric signaling in biofilms. A gate protein (TrkA) directing potassium ion channels was recently identified as generator of potassium ion waves, supporting nutrient supplies to reach the inner biofilm layers. It is conceivable that the persistence of clinical biofilms might be associated with electric signaling mediated by a concerted potassium release.

Materials/methods: To visualize electric signaling in B. subtilis biofilms, a specialized thin agar method (STAM) was developed. Two microliter minimal medium were spotted in a µ-dish (ibidi GmbH) and covered with a thin, pre-fabricated layer of agar (1.5 mm thickness). The agar was pierced with an insect needle to inoculate the interspace between agar and dish bottom. After 5.5 h incubation at 37 °C, Thioflavin T, which migrates into the bacterial cells proportional to the negativity of the membrane potential, was added to the interspace followed by live cell imaging in the confocal laser scanning microscope for 12 h at 30°C. The obtained images were analyzed using Fiji. Bacteria were segmented by automatic thresholding and mean pixel intensities were plotted over time to evaluate the changes of bacterial membrane depolarization.

Results: Using STAM, an oscillating fluorescent signal could be captured from starving B. subtilis populations, verified by analysis of mean pixel intensities. Membrane depolarization events due to potassium release ultimately ends after 20 hours of cultivation.

Conclusions: The STAM assay is a simple method to study electric signaling in bacterial biofilms which uses comparatively cheap consumables. Since the vertical colony expansion is limited by STAM, long-term visualizing of electric communication via live cell imaging becomes possible. In the next step of our study we will investigate the electric signaling capabilities of pathogens such as Staphylococcus epidermidis and Staphylococcus aureus, which also harbor TrkA. In the long run, STAM might be useful to investigate novel approaches to combat biofilms.

Abstract 4884

Chronic hepatitis C care cascade in France: substantial impact of direct-acting antivirals but the path to elimination is still long

Cécile Brouard1*, Josiane Pillonel1, Marjorie Boussac1, Victor De Ledinghen2, Antoine Rachas3, Christine Silvain4, Nathalie Lydié3, Stéphane Chevaliez2, Corinne Pioche1, Julien Durand1, Florence Lot2, Elisabeth Delarocque-Astagneau6

1Santé publique France, Saint-Maurice, France, 2Bordeaux University Hospital, Pessac, France, 3French National Health Insurance, Paris, France, 4Poitiers university hospital, Poitiers, France, 5Henri Mondor University hospital, National Reference Centre for Viral Hepatitis B, C and Delta, Créteil, France, 6Versailles Saint-Quentin University, Montigny-le-Bretonneux, France

Background: The World Health Organization (WHO) has targeted the Hepatitis C Virus (HCV) elimination by 2030, to ensure that 90% of people with chronic infection are diagnosed and 80% are treated. France has planned to achieve this goal by 2025. We aimed to estimate the cascade of care (CoC) for chronic hepatitis C in mainland France in 2011 and in 2016, to initiate the monitoring of HCV elimination and to assess the impact of direct-acting antivirals (DAAs) on the CoC.

Materials/methods: The numbers of people (1) with chronic HCV infection, (2) aware of their status, (3) in care for HCV and (4) receiving antiviral treatment were estimated for 2011 (18-80 years) and 2016 (18-75 years).

Estimates for 1) and 2) were based: on modeling studies for 2011; on a national cross-sectional survey with a virological sub-study conducted among randomly selected individuals from the general population for 2016. Estimates for 3) and 4) were made from the National Health Data System, that covers the entire French population, by constructing an algorithm for identifying people in care for HCV and by taking into account all antiviral treatments.

Results: Between 2011 and 2016, the number of people with chronic HCV infection decreased by 31%, from 192,700 (95% Credibility interval: 150,900-246,100) to 133,500 (95% Confidence interval: 56,900-312,600) (Figure). The proportion of people aware of their infection rose from 58% in 2011 to 81% in 2016. In the same period, the number of people in care for HCV increased by 23% (representing 26% of those infected in 2016) while the number of people under treatment increased by 25% (representing 12% of those infected in 2016).

Conclusions: This work provides, for the first time, estimates of the HCV CoC in mainland France and suggests a substantial impact of DAAs. However, access to care and treatment for infected people remained insufficient in 2016 in order to reach WHO elimination targets. Further studies are needed to estimate the CoC among specific populations including people who inject drugs.

Abstract 4886

**The predictive performance of a model averaging approach is superior over using distinct population pharmacokinetic models in model-informed precision dosing of vancomycin**

David William Uster*1, Sophie Stocker2,3, Jane Carland2,3, Ric Day2,3,4, Sebastian Wicha1

1University of Hamburg, Dept. of Clinical Pharmacy, Institute of Pharmacy, Hamburg, Germany, 2St Vincent’s Hospital Sydney, Dept. of Clinical Pharmacology & Toxicology, Darlinghurst, Australia, 3UNSW Sydney, St Vincent’s Clinical School, Sydney, Australia, 4UNSW Sydney, School of Medical Sciences, Sydney, Australia

**Background:** Currently, the recommendation for therapeutic drug monitoring (TDM) of vancomycin is shifting towards AUC-guided dosing through model-based precision dosing (MIPD). Selecting an inadequate model from the ‘wrong’ population leads to incorrect prediction of vancomycin exposure and therefore potentially inappropriate dose recommendations [Broeker et al. CMI, 2019]. The aim of the present study was to derive and evaluate a model averaging algorithm (MAA), which automates the model selection process and thus eases the clinical application of MIPD.

**Materials/methods:** The MAA was developed by estimating individual pharmacokinetic parameters with four population pharmacokinetic models and weighting the forecasted concentration by the individual model fit. First, a simulation study was conducted using the four models developed in diverse populations [extremely obese, trauma and critically ill]. Subsequently, the MAA was applied to 264 hospitalized and critically ill patients for which routine vancomycin TDM had been conducted. The predictive performance of the MAA using all model jointly was compared to the performance of the individual models on prospectively measured concentrations. Relative bias (rBias) and relative root mean square error (rRMSE) were used to determine accuracy and precision, respectively.

**Results:** The MAA detected the correct model in 3/4 of the simulation cases supplying samples from only one dosing interval. This pattern increased when samples from more dosing intervals was supplied.

MAA applied to the heterogenous clinical dataset resulted in an inaccuracy of less than 1% (rBias) with a higher precision than the best single model. While the predictive performance of the single models [Fig 1 left panels] varied substantially, MAA using these models jointly resulted in unbiased and most precise predictions regarding both a priori prediction [Fig 1(a)] and Bayesian forecasting [Fig 1(b)-(c)]. The MAA performed even better than the model of Goti et al. (2018) that was recently evaluated best in vancomycin Bayesian forecasting.

**Conclusions:** MAA overcomes one of the major difficulties to implementation of MIPD, which is patient-individual selection of the adequate population pharmacokinetic model. Especially if the underlying population of the individual remains unclear or the patient displays atypical pharmacokinetics, MAA can provide a more reliable Bayesian forecast. Implementation into MIPD software [e.g. TDMx] is warranted.

**A multi-site study comparing a commercially-prepared dried MIC susceptibility system to the CLSI/ISO broth microdilution method for cefepime-taniborbactam (formerly cefepime/VNRX-5133) using Gram-negative non-fastidious organisms**

Thomas Lewis¹, Dylan Staats¹, Nicole Holliday¹, Cindy Knapp¹, Scott Killian¹, Brooke Olson², Cory Pike¹, Erin Higdon², Rachel Schoone², Thomas R. Fritsche², Amy Gattis³, Noelle Waugh², Kirk Doing³, Patrick Von Stein¹, Anna Goer¹, Kate Knight¹, Anne Butler⁵, David Paisey⁵, Susan Cusick⁶, Greg Moeck⁶

¹Thermo Fisher Scientific, Oakwood Village, United States, ²Marshfield Clinic Health System, Marshfield, United States, ³Centura Health Corporation, Colorado Springs, United States, ⁴Institut für Medizinische Laboratoriumsdiagnostik (IML) Bochum GmbH, Bochum, Germany, ⁵Thermo Fisher Scientific, East Grinstead, United Kingdom, ⁶VenatoRx Pharmaceuticals, Inc., Malvern, United States

**Background:** Cefepime-taniborbactam (FTB; formerly cefepime/VNRX-5133) (Venatorx Pharmaceuticals, Malvern, PA) is an investigational combination of a fourth generation cephalosporin and a novel boronate-based beta-lactamase inhibitor (BLI) with *in vitro* activity against serine and metallo beta-lactamases. A 4-site evaluation was performed to determine the accuracy and reproducibility of FTB susceptibility testing against non-fastidious gram negative organisms using the Thermo Scientific™ Sensititre™ dried MIC susceptibility system compared with the CLSI (M07, M100)/ISO 20776-1, ISO 20776-2 (CLSI/ISO) reference broth microdilution (BMD) method.

**Materials/methods:** The Sensititre system with FTB in the dilution range of 0.004/4-64/4 mg/L was used to test 734 recent clinical and challenge isolates and 10 reproducibility isolates. Microorganisms tested included 110 *E. coli*, 203 *Klebsiella* spp., 76 *Enterobacter cloacae*, 50 *Citrobacter* spp., 25 *S. marcescens*, 76 *Proteus* spp., 46 *Providencia* spp., 94 *M. morganii* and 54 *P. aeruginosa*. The Sensititre system was inoculated per manufacturer’s instructions. BMD was performed per CLSI/ISO guidelines. Recommended CLSI quality control (QC) organisms were tested daily and all results were within the published QC ranges.

**Results:** FTB MIC results on the Sensititre system were comparable to those determined by CLSI/ISO BMD, with rates of essential agreement (EA; MICs +/- 1 log₂ dilution) of 96.6% by autoread and 96.5% by manual read for *Enterobacteriaceae* and of 100% for both autoread and manual read for *P. aeruginosa*. Overall agreement for reproducibility (MICs +/- 1 log₂ dilution of the modal MIC) using autoread and manual read was 98.1% and 99.7%, respectively.

**Conclusions:** The Sensititre system demonstrated an equivalent level of performance compared to the CLSI/ISO BMD method when testing cefepime-taniborbactam against non-fastidious gram-negative organisms. The high level of agreement obtained by the Sensititre system and the CLSI/ISO BMD method suggests that it is an acceptable method for susceptibility testing of FTB against *Enterobacteriaceae* and *P. aeruginosa*.

Surrogate analysis of ertapenem to predict activity of tebipenem against Escherichia coli and Klebsiella pneumoniae collected from UTIs in Europe and the United States in 2019

Ian Critchley*1, Nicole Cotroneo1, Michael Pucci1, Akash Jain1, Rodrigo E. Mendes2

1Spero Therapeutics, Cambridge, United States, 2JMI Laboratories, North Liberty, United States

Background: Tebipenem (TBP) is an oral carbapenem being developed for the treatment of complicated urinary tract infections (cUTIs). Escherichia coli (EC) and Klebsiella pneumoniae (KP) are predominant uropathogens where resistance to oral agents represent an unmet need. TBP is active against most extended spectrum β-lactamase-producing uropathogens. Development of new agents on commercial susceptibility testing devices continues to lag behind drug development and surrogate testing may be an option for microbiology laboratories until devices are commercially available. The goal of the study was to assess the ability of ertapenem [ETP] to serve as a surrogate for predicting susceptibility (S) to TBP.

Materials/methods: A total of 1910 Enterobacteriaceae (ENT) from UTIs in Europe and United States were collected in 2019 as part of the STEWARD Surveillance program. Isolates were centrally tested for S to TBP and ETP using CLSI methods. Since no breakpoints for TBP are currently available a tentative PK/PD cut off value of 0.12 μg/mL was used to assess S of isolates to TBP and the CLSI/EUCAST breakpoint of 0.5 μg/mL was used to assess S to ETP.

Results: Among ENT, TBP inhibited 95% at ≤0.12 μg/mL and ETP inhibited 96% at ≤0.5 μg/mL with MIC90 values of 0.12 and 0.06 μg/mL, respectively. A categorical agreement (CA; susceptible) rate of 97.2% was observed between ETP and TBP for all ENT. For both EC (N = 1172) and KP (N = 293) the CA S rate was 100%. Among E. cloacae (N = 77) the CA S rate was 98.3% with only one very major error for ETP S isolate that was NS to TBP. The CA S rate for P. mirabilis was 85.5% with 16 ETP S isolates with TBP MICs >0.12 μg/mL.

Conclusions: TBP and ETP achieve 95% inhibition of ENT using PK/PD cut off value of 0.12 μg/mL for TBP and CLSI/EUCAST breakpoint of 0.5 μg/mL for ETP. ETP may be a useful surrogate to predict activity of TBP especially for EC and KP where the CA S rate was 100%. Once final breakpoints have been established for TBP the CA S rates will need to be confirmed.

Presenter email address: icritchley@sperotherapeutics.com
Background: Chimeric Antigen Receptor T cell (CAR-T) therapy has recently been a major breakthrough in the treatment of relapsed/refractory hematological malignancies. We aimed to describe incidence and epidemiology of infections in a real life cohort of patients treated with CD19 CAR-T cell therapy.

Materials/methods: Medical chart retrospective review of hematological patients receiving CD19 CAR-T cells at one university hospital in Barcelona, from May 2017, to September 2019. Descriptive study of all infections with positive microbiological results occurring from the initial treatment day to 150 days.

Results: A total of 41 patients have been treated with CD19 CAR-T cell therapy. Median age was 32 years (IQR 23-48.5 years) and underlying hematological malignancies were acute lymphoblastic leukemia (n=28, 68.3%), non-Hodgkin lymphoma (n=11, 26.8%) and refractory CLL (n=2, 4.9%). A total of 20 (48.8%) patients had 42 episodes of infection (25 bacterial, 15 viral and 2 invasive fungal infections): 17 within the first 30 days, and 24 between 31 and 150 days. Table 1 describes infections epidemiology. There were two infection-related deaths (4.9%) in one patient with severe Clostridium difficile colitis and one patient with multidrug resistant Pseudomonas aeruginosa ventilator-associated pneumonia.

Conclusions: The incidence of proven infection in CD19 CAR-T cell immunotherapy was 48.8%, similar to that of other hematological high-risk patients with intensive chemotherapy. Serious bacterial, viral and fungal infection occurred but infection related mortality rate was low.

Abstract 4890

**Laboratory-confirmed seasonal influenza virus infection in Qatar: 2016-2018 national surveillance data**

Joanne Daghal Nader¹, Ali Omrani², Muna Al-Maslamani¹, Peter V. Coyle°, Mohamad Shebash¹, Samar A. Hashim¹

¹Hamad Medical Corporation, Doha, Qatar

**Background:** Despite widely available annual immunisation and antiviral therapy, seasonal influenza continues to cause considerable morbidity and mortality. Limited data are available regarding the demographic and virologic characteristics of seasonal influenza in Qatar. The aim of this study was to assess the incidence and clinical impact of laboratory-confirmed influenza infection in Qatar during the years 2016 to 2018.

**Materials/methods:** Qatar Influenza Surveillance Programme involves offering laboratory testing for all individuals who present with an influenza like illness (ILI) to any primary health centre or hospital department. Upper respiratory samples are submitted to the National Virology Laboratory based at Hamad Medical Corporation, Doha, where they are tested using RT-PCR (Xpert Flu, Cepheid, Sunnyvale, California) and multiplex PCR (FTD Respiratory pathogens 21, Fast-Track Diagnostics, Esch-sur-Alzette, Luxembourg). Surveillance results, hospital admissions and mortality data were retrieved retrospectively from electronic databases. All samples tested between January 2016 and December 2018 were included. Stata (StataCorp LLC, College Station, Texas) was used for descriptive statistics. Incidence rates (IR) are reported by 100,000 population. Population data are based on those reported by Qatar Planning and Statistics Authority. The study was approved by the Institutional Review Board at Hamad Medical Corporation.

**Results:** Over the study period, Influenza Virus was detected in 19,339 (1.3%) out of 1,444,855 specimens from individuals with ILI, corresponding to an overall IR of 244 per 100,000 population. Of those with confirmed Influenza, there were significantly more males (56% versus 46% females, P < 0.001) and younger age groups (35% from those aged 0 to 4 years and 19% from 5 to 14 years age group). Influenza A (71.0%) predominated, nearly half (48.7%) of which were H1N1pdm09 type. Significantly more cases were diagnosed during the months of October to December compared with January to March (63.0% versus 18.0%, P < 0.001) (Figure). During the year 2018, there were 315 (3.0%) admissions to critical care units due to Influenza-related complications and 7 deaths (in-hospital mortality 2.4%).

**Conclusions:** The incidence of laboratory-confirmed seasonal Influenza is high in Qatar. However, children and young adults are most commonly affected, and hence relatively low rates of severe complications and mortality are observed.

**Abstract 4892**

**CrpP-like fluoroquinolone-modifying enzymes among *Pseudomonas aeruginosa* clinical isolates in Europe**

Jose Manuel Ortiz De La Rosa*1,1, Patrice Nordmann1, Laurent Poirel1

1University of Fribourg, Fribourg, Switzerland

**Background:** Transferable mechanisms of resistance to quinolones have been identified in Gram-negative bacteria, corresponding to Qnr-type pentapeptide proteins, AAC(6')-Ib-cr, OqxAB or QepA. Recently, a plasmid-encoded 65 amino-acid long ciprofloxacin-modifying enzyme, namely CrpP (CrpP1) was identified in *Pseudomonas aeruginosa* in Mexico. The CrpP1 enzyme conferred reduced susceptibility (7.5 fold) to ciprofloxacin once produced in *Escherichia coli*. In-silico analysis identified 37 different CrpP variants. Our aim was to evaluate the dissemination, genetic support and impact on susceptibility to quinolones of this novel resistant determinant.

**Materials/methods:** A collection of 100 multidrug-resistant and clonally-unrelated *P. aeruginosa* clinical isolates, including ESBL (n=17) and carbapenemase (n=74) producers, recovered in Europe was tested by PCR and sequencing. Whole genome sequencing (WGS) was performed in several isolate to determine the location of this gene. In order to evaluate the impact of the different CrpP enzymes identified, the corresponding *crpP*-like genes encoding CrpP1 and CrpP2 enzymes were cloned in pUCp24 and transformed either in *E. coli* TOP10 and in *P. aeruginosa* PAO1. Capacity of mobilization of the Pathogenicity Islands (PAGI) were tested by PCR including primers in the extremities of the PAGI. WGS was performed to identify the genetic location of the *crpP* genes.

**Results:** A total of 49/100 positive isolates and 5 CrpP variants were identified by PCR and sequencing. WGS showed that the positive strains carried the *crpP* genes always located on a PAGI. MICs results showed a decreased MIC for ciprofloxacin (7.5-fold), for the *E. coli* clone producing CrpP2, but not CrpP1. For that latter, a 2-fold decreased MIC value was observed in *P. aeruginosa* only. Noteworthy, a 3-fold increase in levofloxacin resistance was observed once CrpP2 was produced in *E. coli*. Instead, MICs of levofloxacin was increased by 2-fold once CrpP2 was produced by *P. aeruginosa*. PCR assays identified a circular form of the PAGI island.

**Conclusions:** We first report the occurrence of *crpP*-like genes among *P. aeruginosa* clinical isolates in Europe. We showed that susceptibility to fluoroquinolones might slightly vary depending on the nature of the Crp protein. Acquisition of those genes was mediated by a PAGI functional element.

Abstract 4896

**IS26-mediated transfer of blaNDM-1 as the main route of resistance transmission during a polyclonal, multispecies outbreak in a German hospital**

Robert Weber*1, Michael Pietsch1, Andre Frühauf2, Yvonne Pfeifer1, Maria Martin2, Dirk Luft2, Sören G. Gatermann3, Niels Pfennigwerth3, Martin Kaase34, Guido Werner1, Stephan Fuchs1

1Robert Koch Institute, Wernigerode, Germany, 2SLK-Kliniken, Heilbronn, Germany, 3Ruhr-University, Bochum, Germany, 4University Medicine Göttingen, Göttingen, Germany

**Background:** One of the most demanding challenges in infection control is the world-wide dissemination of multidrug-resistant bacteria in clinical settings. Especially the increasing prevalence of carbapenemase producing Gram-negative pathogens poses an urgent threat to public health, as these enzymes confer resistance to almost all β-lactam antibiotics including carbapenems.

In this study, we report a prolonged nosocomial outbreak of various NDM-1-producing Enterobacterales species due to clonal spread and cross-species exchange of blaNDM-1-carrying plasmids and transposons.

**Materials/methods:** Between July 2015 and September 2017, a total of 51 carbapenemase-positive strains were collected from 38 patients and three environmental sources in a German hospital. To investigate the clonal relationship and involved mechanisms of blaNDM-1 gene transfer, conjugation assays, molecular typing and whole genome sequence analyses were performed.

**Results:** The metallo-β-lactamase gene blaNDM-1 was found to be present in 35 of 51 carbapenemase-positive isolates of which seven additionally carried the carbapenemase gene blaKPC-2. KPC-2 could also be detected within the remaining 16 NDM-1-negative isolates. Core genome MLST revealed different clusters of closely related isolates of E. coli, K. pneumoniae, C. freundii, M. morganii or E. cloacae indicating clonal spread of NDM-1 producing bacteria. The detailed reconstruction of plasmids revealed that in all outbreak-associated isolates blaNDM-1 was located on composite transposons similar to Tn125, that has previously been described for Acinetobacter baumanii. In contrast to Tn125, these structures were flanked by IS26 elements, that might facilitate horizontal gene transfer. Moreover, identical plasmids were found to be shared by E. coli and M. morganii isolates.

**Conclusions:** Our results highlight the importance of detailed genome-based analyses for resolving complex nosocomial outbreaks that include both, clonal spread of MDR pathogens and inter-species resistance gene transfer. It remains to be elucidated if standard infection prevention precautions are as effective for preventing horizontal resistance spread as it is for controlling clonal dissemination of pathogens.

Abstract 4898

Genomic identification of clinically relevant Mycobacterium species by target sequencing
Valérie Collin*1, Françoise Allard2, Marilyne Rumigny2, Fabien Javerliat3

1bioMérieux, La Balme-les-Grottes, France

Background: The genus Mycobacterium contains nearly 200 species and among them, some species of clinical interest due to their severe human pathogenicity. Mycobacterium taxonomy has recently being reviewed and the genus is now divided into 5 distinct groups, Mycolicibacterium, Mycobacteroides, Mycolicibacter, Mycolicibacterium and Mycobacterium, the latter including all the human pathogens. Taken into account this new taxonomy, a molecular analysis was performed within each clade to set-up an easy molecular method to identify the best relevant species. Public genomes were analyzed by similarity and target sequences on partial genes of 16S, rpoB and hsp65 genes.

Materials/methods: Whole genome analysis was done with an ANI approach (average nucleotide identity) on 176 NCBI genomes from type strains and collection strains if available (89 Mycobacterium, 53 Mycolicibacterium and 34 Mycobacteroides), the two other clades being not clinically relevant. Target sequencing was done by phylogenetic classification using UPGMA/Neighbor-joining with public sequences of 16S, partial rpoB (711pb) and partial hsp65 (603pb) genes.

Results: The ANI study showed more than 99.9% homology between subspecies of Mycobacterium abscessus and those of Mycobacterium avium. The analysis reveals also a high similarity between some species which have recently been reclassified [M.intracellulare and M.paraintracellulare, M. bouchedurhonense and M.avium, M.intracellulare and M.chimaera]. The target sequencing analysis showed that 16S was not enough discriminant, especially for the Mycobacteroides group. Analysis of rpoB and hsp65 sequences separately allows a correct identification at the species level but is not sufficient at the subspecies level. The concatenation of rpoB and hsp65 allows the discrimination of subspecies such as those of Mycobacteroides abscessus and Mycobacterium intracellulare.

Conclusions: ANI programs on whole genomes are not discriminative enough to identify all Mycobacterium species of interest, especially at the subspecies level. Target sequencing using partial rpoB and hsp65 concatenated genes allows to identify all relevant pathogenic Mycobacterium species, at the subspecies level taken into account the new taxonomy. This in-silico analysis has to be completed with internal strains sequencing before to be used in our laboratory.

Abstract 4903

Decision tree algorithm that differentiates dengue from other febrile illnesses at the early stage of the disease: a health centre-based prospective observational cohort study

Adriana Tami*, Zoraida Velasco-Salas², Maria F. Vincenti-Gonzalez¹, Erley Lizarazo¹, Gloria Sierra³, Paula Triana³, Johannes G.M. Burgerhof¹, Jan C. Wilschut¹

¹University Medical Center Groningen, Groningen, Netherlands, ²University of Carabobo, Departamento de Biología, Facultad Experimental de Ciencias y Tecnología, Naguanagua, Venezuela, ³Instituto de Investigaciones Biomedicas (BIOMED UC), Maracay, Venezuela

Background: The acute phase of dengue, a viral vector-borne disease, begins with fever and non-specific symptoms frequently indistinguishable from other febrile illnesses (OFI). Early diagnosis can reduce case fatality from 20% to <1%, but molecular diagnosis is hardly available at primary care. We aimed to identify parameters that could differentiate dengue from OFI at the early stage of the disease (≤72h from fever onset) and to design a decision-tree algorithm using clinical features and routine laboratory tests.

Materials/methods: Clinical and laboratory data from patients presenting within 72h of disease onset to three primary health centres and a tertiary hospital in a dengue hyperendemic city in Venezuela, were collected during three years. Multivariate logistic regression analysis identified parameters independently associated with a laboratory confirmed dengue infection (main outcome variable) before and after day 3 from fever onset. A diagnostic decision tree algorithm was constructed based on multivariate logistic regression analysis.

Results: Of 254 patients that met the inclusion criteria, 112 (44.1%) had an acute dengue infection while 142 were classified as OFI. We constructed a diagnostic algorithm using white blood cells (WBC) count, rash, mean corpuscular haemoglobin (MCH) levels and haemorrhagic manifestations in sequential order that distinguished dengue from OFI with a sensitivity of 88% and a specificity of 63%. Multivariate analysis determined that the presence of rash, haemorrhagic manifestations and a decrease of platelet counts, WBC count and MCH were independently associated with dengue during the first 3 days of the disease. Finally, a decrease of cholesterol and an increase of albumin were the two biochemical parameters independently associated with dengue at the early phase of the disease.

Conclusions: The proposed diagnostic algorithm may be a useful instrument to help clinicians in the early identification of dengue patients. This may substantially decrease fatalities due to timely treatment and avoid overburdening of the health system owing to misdiagnosis.

Prevalence of resistant and virulence genes in Enterococcus faecium and Enterococcus faecalis isolated from blood culture in haematological patients in Russia

Anastasia Fedorova Mironova*, Svetlana Khrulnova1, Galina Klyasova1

1National Research Center for Hematology, Moscow, Russian Federation

Background: The aim of this study was to investigate the prevalence resistant and virulence genes in E. faecium and E. faecalis isolated from blood culture in haematological patients.

Materials/methods: Enterococcus spp. were isolated from blood culture in haematological patients in six Russian hospitals from 2002 to 2018. Susceptibility to glycopeptides was determined by broth microdilution method (CLSI, 2018). Virulence genes (esp, hyl, asa1, cylA and gelE) in E. faecium and E. faecalis and vancomycin resistance genes (vanA, vanB and vanD) in Enterococcus spp. were detected by multiplex PCR.

Results: A total of 487 Enterococcus spp. were evaluated, of them 393 (80.7%) were E. faecium and 94 (19.3%) E. faecalis. Resistance to vancomycin was detected in 71 (18.1%) E. faecium, of them 47 (66.2%) carried vanA genes and 24 (33.8%) vanB. One (1.1%) E. faecalis was vancomycin-intermediate [MIC 16 μg/ml] with vanD gene. The distribution of virulence genes in E. faecium and E. faecalis is presented in the table. The predominant genes in E. faecium were esp (71.2%) and hyl (53.7%), in E. faecalis were gelE (67%) and asa1 (63.8%). Differences in the detection of all genes (p<0.0001) were found between E. faecium and E. faecalis. Up to 42% of E. faecalis isolates had ≥3 virulence genes whereas 82.2% of E. faecium isolates were found to carry 1-2 virulence genes only. All investigated virulence genes were absent in 15.3% E. faecium and 3.2% E. faecalis (p<0.0001). Gene hyl was detected less frequently [43.7% vs. 55.9%, p=0.066] in vancomycin-resistant E. faecium (VREF) compared to vancomycin-susceptible E. faecium (VSEF) and gene cyl was absent in VREF. No differences in distribution of virulence genes in vanA and vanB VREF were found, except of asa1 gene, which was absent in vanB VREF.

Conclusions: The rate of vancomycin-resistance was higher in E. faecium than in E. faecalis with prevalence of vanA [66.2%] compared to vanB [33.8%]. Genes esp and hyl prevailed in E. faecium, genes gelE and asa1 in E. faecalis. Multiple virulence genes in E. faecalis were significantly more prevalent than in E. faecium isolates. In VREF compared to VSEF gene hyl was detected less frequently and cyl gene was absent.

Molecular epidemiology of vancomycin-resistant enterococci: changing paradigms at the crossroads of Europe

Carlos Correa-Martinez1, Annette Jurke2, Janne Schmitz1, Stefanie Kampmeier1, Alexander Mellmann1

1University Hospital Münster, Institute of Hygiene, Münster, Germany, 2North Rhine-Westphalian Centre for Health, Section Infectious Disease Epidemiology, Bochum, Germany

Abstract 4905

Background: Vancomycin-resistant enterococci (VRE) are emerging pathogens of nosocomial infections worldwide and their mortality in bloodstream infections (VREBI) can reach 50%. In Germany, vancomycin-resistance in invasive Enterococcus faecium isolates increased from 11.9% (2016) to 23.8% in 2018. To investigate the epidemiology of VREBI and of the underlying isolates, we established a network of VRE surveillance in North-Rhine Westphalia (NRW), the largest German state located centrally in the Schengen free movement area, accounting for 21.6% of the German population.

Materials/methods: Between 2016 and 2018, we included VREBI isolates from all inpatients residing or hospitalized in NRW at the time of diagnosis. We determined the multilocus sequence type (ST) and vancomycin resistance determinants. Results were geographically mapped by administrative districts according to the postcode of the place of hospitalization.

Results: In total, 493 isolates were analyzed. The incidence of VREBI increased sharply during the study period: 0.52, 0.88 and 1.36 per 100,000 inhabitants in 2016, 2017 and 2018, respectively. The distribution of the resistance determinants varied drastically over time. Whereas a predominance of vanA (64.5% of all isolates) over vanB was observed in 2016, in 2017 an inversion of this distribution occurred with vanB-positive isolates almost doubling to 68.6% and reaching 83.2% of all analyzed isolates in 2018. The overall most common ST was ST117, which carried vanB in 91.9% of the cases and showed a steadily increasing incidence (45.2% in 2016, 77.5% in 2018). Other predominant STs were ST80 and ST203.

Conclusions: VREBIs are a rising problem in NRW, a situation also reported in neighboring states and countries. This can be attributed to the increasing incidence of ST117, an ST that has rapidly spread from east to west. The common association of ST117 with vanB has led to the fundamental epidemiological change, with vanB now widely outnumbering vanA, historically the predominating resistance determinant among VRE in Europe and other regions of the world. Our data can be used for the development of infection prevention policies, as vanB-positive VRE are -until now- known to be teicoplanin-susceptible.

Plasma population pharmacokinetic modelling of cefepime and enmetazobactam in patients with complicated urinary tract infections

Matthias Machacek¹, Fabian Bernhard¹, Massimiliano Mameli², Adam Belley³, Philipp Knechtle*³

¹LYO-X, Allschwil, Switzerland, ²Aptuit (Verona) Srl, an Evotec Company, Verona, Italy, ³Allegra Therapeutics SAS, Saint Louis, France

Background: Infections caused by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae account for more than 20,000 deaths annually in the EU and US. Enmetazobactam is a novel β-lactamase inhibitor belonging to the penicillanic acid sulfone class, targeting ESBLs. The combination enmetazobactam with cefepime is currently being investigated in a Phase 3 study of patients with complicated urinary tract infections (cUTI) or acute pyelonephritis (AP). In this study, population pharmacokinetic (PK) models for cefepime and enmetazobactam were established from healthy participants and cUTI patients.

Materials/methods: Plasma PK samples were analyzed from healthy participants receiving cefepime (n=57) and enmetazobactam (n=132) in three phase 1 studies and from patients receiving cefepime (n=43) and enmetazobactam (n=29) in a phase 2 study of cUTI. Population PK characteristics were described and the relationship between different subject-specific factors and model parameters were assessed. The effect of infection on disposition was assessed by testing disease covariates on fixed and random effects for all PK parameters.

Results: Cefepime and enmetazobactam PK were similar and best described with a two-compartment, linear PK model with key parameters summarized in the table. Statistically significant covariates for cefepime disposition were estimated glomerular filtration rate (eGFR) on clearance and peripheral volume of distribution (Vₚ), body weight on central Vₖ, and albumin on peripheral Vₚ. Significant covariates for enmetazobactam disposition were eGFR on clearance and peripheral Vₚ, body weight on both central and peripheral Vₚ, and gender and infection on peripheral Vₚ. Interindividual variability for clearance and central Vₖ was larger in cUTI patients for both agents.

Conclusions: The population PK models for cefepime and enmetazobactam effectively predict exposures in cUTI patients, including subjects with renal impairment or undergoing hemodialysis. These models will support Monte-Carlo simulations and target attainment estimations in this patient population.

Community-acquired *Clostridioides difficile* infection: a prospective study in an unselected population

Laura Villar Gomara*, Silvia Noemi Vazquez Cuesta1, Luis Alcalá1, Mercedes Marín1, Patricia Muñoz1, Emilio Bouza1, Elena Reigadas Ramirez1

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

**Background:** *Clostridioides difficile* infection (CDI) is the most common cause of hospital acquire diarrhea in developed countries. However, during the last decades, there has been noted an increment in CDI cases acquired in the community (CA-CDI). These patients purportedly have less known risk factors and are frequently unrecognized or underdiagnosed. Prospectively evaluated CDI series without a restrictive criteria or selection bias are scarce. The objective of this study was to assess the epidemiology, clinical characteristics and outcome of CA-CDI in an unselected population.

**Materials/methods:** We conducted a prospective study ([Jul 2018-ongoing](https://example.com)) in which systematic testing for toxigenic *C. difficile* on all diarrhoeic stool samples was performed regardless of the clinician’s request. The microbiology laboratory receives samples from hospitalized patients and from all outpatient centers within our catchment area. All episodes of CDI were prospectively collected and classified attending to the source of acquisition. Patients aged >18 years who fulfilled criteria for CA-CDI were enrolled and monitored at least 2 months after their last episode. Epidemiological and clinical data were recorded.

**Results:** During the study period, 860 samples were positive for toxigenic *C. difficile*, corresponding to 638 patients. We identified 184 CA-CDI patients, out of which 90 have completed the study and fulfilled CDI criteria. Mean age was 56.5 years and 64.4% were female. Overall, 54.4% had community onset (CO-CA-CDI). 31.1% of the episodes would have gone undiagnosed owing to lack of clinical suspicion. Overall, only 6.7% had no underlying disease, the most frequent underlying diseases were gastrointestinal (52.2%), cardiovascular (44.4%), metabolic (43.3%), respiratory, endocrine and rheumatologic (28.9%). The most frequent risk factors were having received antibiotic treatment (68.9%) and having received PPI (67.8%). Most episodes were mild to moderate (73.3%) and 84.4% were treated for CDI. Recurrence (R-CDI) occurred in 11.9% of patients. Overall mortality was 7.8% and mortality attributable to CDI was 1.1%.

**Conclusions:** Even in a setting with optimal diagnostic tests, one third of CA-CDI cases would have gone undiagnosed due to lack of clinical suspicion. Most CA-CDI episodes were mild to moderate, however there was a significant proportion of R-CDI and a CDI-related mortality episode.

Abstract 4911

**Clinical validation of the BD CT/GC/TV2 for BD MAX system in vaginal, endocervical and female urine specimens**

Barbara Van Der Pol*, Edith Torres-Chavolla², Salma Kodsi², Charles K. Cooper¹, Thomas Davis⁴, Kenneth H Fife⁵, Stephanie Taylor⁶, Michael Augenbraun⁷, Laura Bachmann⁸, Charlotte Gaydos⁹

¹University of Alabama at Birmingham, Birmingham, United States, ²BD Life Sciences, Sparks, United States, ³BD Lifesciences, Sparks, United States, ⁴Eskanazi Hospital, Indianapolis, United States, ⁵Indiana University School of Medicine, Indianapolis, United States, ⁶Louisiana State University Health Sciences Center, New Orleans, United States, ⁷SUNY Downstate Medical Center, Brooklyn, United States, ⁸Wake Forest Health Center, Winston, United States, ⁹Johns Hopkins School of Medicine, Baltimore, United States

**Background:** Rates of treatable sexually transmitted infections (STI) continue to increase globally according to national and international public health agencies. In many countries, the prevalence of trichomonas is even higher than that of chlamydia and gonorrhea. Diagnostic systems that support targeted therapy rather than syndromic management are needed in order to improve antimicrobial stewardship. Here we describe the performance of the BD CTGCTV2 assay (pending CE Marking) when using vaginal (VS) or endocervical swabs (ES), endocervical samples in liquid-based cytology (LBC), and female urine (FU) specimens.

**Materials/methods:** Specimens collected from each participant included FU, 4 VS (2 patient- and 2 clinician-collected), 2 ES and 1 LBC specimen. Hologic Aptima® AC2 and TV; and BD ProbeTec™ CTQx/GCQx and TVQx assays were used as references to determine the patient infection status (PIS) (ES/FU for chlamydia and gonorrhea PIS; and VS/ES for trichomonas PIS). For female urine, results from 3 assays were used in a composite molecular comparator reference.

**Results:** Samples were obtained from 2,547 women. Sensitivity estimates using VS were 98.4, 98.8 and 99.4% for chlamydia, gonorrhea, trichomonas, respectively. In the same order, sensitivity estimates were 94.5, 95.3, and 93.8% using ES; 92.7, 92.9 and 91.4% using LBC; and, 98.4, 100 and 100% with FU. All specificity estimates were ≥98.7%. The BD CTGCTV2 assay has dual gonorrhea targets in order to optimize specificity; both targets are required to give a signal for a positive result. The PPV based on observed GC prevalence (1.6%) was ≥91.4% for all specimen types.

**Conclusions:** The BD CTGCTV2 assay uses reagent strips that allow testing in batches up to 24 samples, without reagent loss, on a tabletop instrument. The ability to correctly identify all three of the most prevalent treatable STIs in a small platform may allow local testing to be performed in settings where testing could only be accessed via centralized reference labs previously. This could lead to a reduction in specimen shipping costs and in the total time to results. Adoption of such a system could lead to improved patient management and antimicrobial stewardship by accurately targeting treatment to manage only those pathogens detected.

A retrospective study to evaluate the epidemiology, standard of care, outcomes and resource utilisation in patients with confirmed or suspected infection by a carbapenem-resistant Gram-negative organism in Spain: the CARBAR study part 1, epidemiology of Gram-negative organisms

Juan P. Horcajada1*, Miguel Salavert1, Julián De La Torre Cisneros1, Irene Gracia-Ahufinger1, José Ramón Paño Pardo1, Helem Haydee Vilchez Rueda1, Natividad Benito2, Alba Rivera2, Dolores Sousa Regueiro3, Vicente Estrada Perez4, Maialen Ibarguren Pinilla5, Davide Manissero6, Christopher Longshaw7, Keiko Tone8, Sara Lopes9

1Hospital del Mar, Barcelona, Spain, 2Hospital Universitario y Politecnico la Fe, Valencia, Spain, 3Hospital Universitario Reina Sofía, Cordoba, Spain, 4Hospital Clinico Universitario Lozana Blesa, Zoragaza, Spain, 5Hospital Universitario San Espouses, Illes Balears, Spain, 6Universitat Autònoma de Barcelona, Barcelona, Spain, 7Infectious Diseases Unit, Hospital de la Santa Creu i Sant Pau - Institut d’Investigació Biomèdica Sant Pau, Barcelona, Spain, 8Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 9Complejo Hospitalario Universitario A Coruña [CHUC], Coruña, Spain, 10Hospital Clinico San Carlos, Madrid, Spain, 11Hospital Universitaria Donostia, Donostia, Spain, 12Former Shionogi Europe, London, United Kingdom, 13Shionogi Europe, London, United Kingdom

Background: Antimicrobial resistance is a global threat with potentially devastating consequences and significant costs to society. Carbapenems are customarily reserved for difficult-to-treat Gram-negative (GN) infections, but resistance is increasing; hence, WHO recently classified carbapenem-resistant [CR] Acinetobacter baumannii, Pseudomonas aeruginosa, and Enterobacteriaceae as a critical priority.

CR-GN infections have few effective treatment options, with variable outcomes, and clinical trial evidence is scarce. In this analysis, we describe the epidemiology of patients infected with CR-GN organisms in Spain.

Materials/methods: Ongoing retrospective chart review in Spain. Adult patients admitted to hospital between April 2017-March 2018 were included if they had a confirmed GN bacterial infection and/or positive screening isolate for CR-GN bacteria colonisation. Data collection included microbiological results and patient demographics.

Results: 11,040 patients were included in 5 sites [representing 13,871 GN isolates], of which 1,292 patients (12%) had CR-GN pathogen. Mean age was 62.4 years; 51% were male.

Table 1 shows the distribution of GN pathogens identified. The most prevalent GN species were Escherichia coli representing 47% of all isolates, followed by Pseudomonas aeruginosa (13 %), and Klebsiella pneumoniae (13%).

Non-fermenters represented 63% of all CR-GN isolates. The main species identified in CR-GN was Pseudomonas aeruginosa (39%) followed by Stenotrophomonas maltophilia (19%). Enterobacteriaceae represented 37% of all CR-GN isolates.

Conclusions: 12% of GN isolates are CR-GN across Spain, representing an important segment of this population. Understanding the real-world prevalence of GN and particularly CR-GN infections, where there is the highest unmet medical need, can help to optimise antimicrobial stewardship and infection control programmes, and ultimately improving overall patient’s and healthcare system’s outcomes, which is the focus of this study’s next phase.

Abstract 4914

Transforming care through data transparency: impact on cellulitis therapy standardisation

Sarah Minor*1, Nithin Sankar1, Jordan Burns1, Kaley Calise1, Victor Herrera1

1AdventHealth Orlando, Orlando, United States

Background: Cellulitis is frequently encountered in the acute care setting, leading to over 600,000 admissions annually in the United States. Variations in care can have a substantial impact on patient outcomes including hospital admission rates, overall costs, and hospital length of stay (LOS). With many therapeutic options available to treat cellulitis and wide variety in prescriber antibiotic selection, our team hoped to investigate the benefits of data transparency with the goal of standardizing care for cellulitis.

Materials/methods: This multi-site retrospective review was conducted across 7 AdventHealth campuses in Orlando, FL. The Care Transformation team and Antimicrobial Stewardship Awareness Program developed a 2-phase process to assess the impact of unblinded physician report cards. Both phases included patients >18 years of age admitted with a primary diagnosis of cellulitis DRGs 602 and 603 who also had infectious diseases (ID) physician consultations. Phase one was conducted between January 2017 to June 2018 with phase two in July 2018 to March 2019. A total of 29 ID physicians were included with over 1800 cases included in each time frame. Results for phase 1 (Figure 1) revealed each physician’s unblinded performance compared to de-identified results of their peers. Overall hospital LOS and total cost of antibiotics per case were evaluated to identify variations and subsequent standardizations in practice.

Results: After presentation of unblinded phase 1 data, improvements in both average LOS and antibiotic cost per case were noted. In comparison to phase 1 data, 57% of providers decreased their average LOS in phase 2 from 4.63 days to 4.13 days. Additionally, 48% of providers decreased their average antibiotic cost per case by $30 per case after presentation of unblinded data ($270.11 vs $242.11). This decrease led to a total costs savings of $298,375 during phase 2.

Conclusions: This study identified a wide range of variation amongst ID consultants in phase 1, and through the presentation of unblinded data, led to improvements in standard treatment for cellulitis during phase 2. Presenting data transparently may be beneficial to explore in other infectious disease states.

**In vivo bactericidal activity of minocycline and rifampicin combination in a lung infection model in neutropenic mice**

Wendy Kloezen¹, Aart Van Der Meijden¹, Heleen Van Der Spek¹, Marian Ten Kate¹, Johan W. Mouton¹, Anouk Edwina Muller¹,², Joseph Meletiadis¹,³, Sanne Van Den Berg*¹

¹Department of Medical Microbiology and Infectious Diseases, Erasmus MC University Medical Centre Rotterdam, Rotterdam, Netherlands, ²Department of Medical Microbiology, Haaglanden Medical Centre, The Hague, Netherlands, ³Clinical Microbiology Laboratory, Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Netherlands

**Background:** As development of new antibiotics against multidrug-resistant pathogens is limited, combination therapy may increase efficacy of antibacterial treatment. Minocycline and rifampicin have broad activity against Gram-positive and Gram-negative bacteria but their efficacies are limited because of fast development of resistance. We therefore combined minocycline with rifampicin against *Acinetobacter baumannii* and *Staphylococcus aureus* in a lung infection model in neutropenic mice and determined the bactericidal effects of combination therapy.

**Materials/methods:** Neutropenic mice were challenged with *A. baumannii* 112 or *S. aureus* MUP3199 strains with minocycline/rifampicin MICs 0.063/8 and 0.125/0.008 mg/L, respectively. Treatment was started 2h after intranasal inoculation of 10⁶-10⁷ CFU and continued for 24h. Minocycline and rifampicin were dosed 0.5-2 mg/kg q6h subcutaneously and 4-64 mg/kg q12h per os, respectively (3x5 checkerboard). Mice were euthanized 24h after start of treatment and CFUs were counted with serial quantitative cultures in lung homogenates. The log₁₀ CFU/lung reductions compared to initial bacterial lung burden were calculated for each dosing regimen in duplicate experiments. Dose combinations with statistically significant bactericidal activity (>1-log₁₀ kill) were determined using t-test.

**Results:** Lung CFU in placebo-treated mice increased by 2log₁₀ compared to baseline bacterial burden whereas minocycline monotherapy showed bacteriostatic effect at the highest doses against *A. baumannii* and *S. aureus*. No effect was found with rifampicin monotherapy. When the two drugs were combined, significant bacterial killing of >1-log₁₀compared to start of treatment was found in 5 and 6 out of 15 tested dose combinations for *A. baumannii* and *S. aureus*, respectively at minocycline/rifampicin doses 0.5-2/16-32 mg/kg. The strongest bactericidal activity (-4.5 for *A. baumannii* and -3.2 for *S. aureus*) was found when 32-64 mg/kg q12h of rifampicin was combined with 0.5 mg/kg q6h of minocycline.

**Conclusions:** The addition of rifampicin to minocycline treatment resulted in strong bactericidal activity compared to monotherapy regimens. The combination may overcome fast development of resistance against the drugs alone and therefore warrants further evaluation.

Abstract 4919

**Risk factors for in-hospital mortality in a prospective contemporary cohort of adult patients with infective endocarditis in a cardiac surgery hospital**

Rafael Garrido1,2, Giovanna Ianini Barbosa1, Marcelo Correia1, Luiz Henrique Lemos1, Leonardo Ribeiro-Da-Silva1, Juliana De Andrade1, Daniela Menezes1, Bruno Zappa1, Wilma Golebiowsk1, Clara Weksler1, Cristiane Lamas*1,2,3

1Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil, 2INI - Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, 3Unigranrio Barra da Tijuca, Rio de Janeiro, Brazil

**Abstract third-party references:** Supported by Faperj, Rio de Janeiro.

**Background:** Mortality in infective endocarditis (IE) remains very high, despite availability of surgery and expertise in management.

**Materials/methods:** Risk factors were sought for in hospital mortality in a prospective cohort of adults with definite IE. The Jamovi 1.0.7 software was used for analysis. International Collaboration on Endocarditis CRFs were used for data collection.

**Results:** From January 2006-September 2019, 359 episodes of IE were included; 2/3 of patients were male; over 90% of IE was left-sided. Median age was 47.1 [IQR 34-61]. In hospital mortality was related to age: patients who died were older in all quartiles (Q1, 31 vs 44.8 years; Q2 44 vs 56.5 years; Q3, 56.8 vs 68.3 years, p<0.001), but not to sex. Heart failure, HF (53.4% vs 35.7%, p=0.003), diabetes (19.3% vs 9.3%, p=0.011), hypertension (65.8% vs 42.1%, p<0.001), chronic renal failure, CRF (36.4% vs 14.9%, p<0.001) and coronary artery disease (23% vs 9.3%, p<0.001) were associated with death. Patients who died more often presented acutely (64.7% vs 46.8%, p=0.015) and had hospital-acquired IE (37.5% vs 25.7%, p=0.033). Death was associated with paravalvular abscess (29.5% vs 17.5%, p=0.015), conduction disturbances (17.9% vs 7.9%, p=0.012), persistent bacteremia (10.8% vs 3.6%, p=0.011) and acute renal failure, ARF (50% vs 25.8%, p<0.001), but not with acute onset of HF (65.9% vs 60.1%, p NS). Regarding etiology, mortality was related to coagulase-negative staphylococci (17% vs 6.3%, p=0.002), no difference was found for S.aureus, enterococci or blood culture-negative IE. Candida etiology and Gram negative non HACEK microorganisms affected more often those who died (p NS). Pre-operatively patients who died had significantly more cardiac arrest, need for inotropes, intra-aortic balloon pumps and mechanical ventilation. Of those who died, 93.4% had a surgical indication, but only 64% were operated while of those who survived, 84.8% had surgical indication and 85% had surgery (p<0.001).

**Conclusions:** In hospital mortality was mainly related to previous HF and CRF, as well as ARF. Local infection leading to abscess and heart block were also related to death, as was persistent bacteremia. Hospital acquisition was more frequent. However, S.aureus etiology was unrelated.

Background: HCV is highly variable; 8 genotypes and over 100 subtypes have been identified so far. Recently, “unusual” subtypes in patients from African and Asian origin have been associated with lower response rates to DAAs. This was ascribed to polymorphisms at relevant amino acid positions as compared to the most sensitive subtype in the same genotype. Using the international SHARED network, we aimed to assess the prevalence of post-treatment failure RASs and their patterns among unusual HCV subtypes, defined as GT1 non1a/b, GT2 non2a/b, GT3 non3a, GT-4 non4a/d, GT5, and GT6.

Materials/methods: We extracted data from the SHARED database of patients who did not achieve a sustained virological response on DAA therapy. Only patients who failed DAA strategies recommended by EASL guidelines were included. Genotype and subtypes were sequence-derived, and analyses grouped by HCV subtype. RASs were analysed at positions according to the 2018 EASL guidelines.

Results: We identified a 6% prevalence (73/1176) of unusual subtypes among patients who failed NSSA inhibitor-containing regimens, including: GT1g [n=2], GT1l [n=5], GT2c [n=8], GT2i/j [n=1 each], GT3h [n=7], GT3b [n=6], GT3k [n=2], GT3g [n=1], GT4r [n=14], GT4v/4ns [n=3 each], GT-4g/4o [n=2 each], GT-4f/4k/4n/4q/4t [n=1 each], GT6q [n=3], GT-6e/6h/6p/6r/6xe [n=1 each]. Patients were treated with SOF+LDV +/-RBV [n=18], SOF+DCV +/-RBV [n=15], SOF+VEL +/-RBV [n=13], GZR+EBR [n=11], 2D/3D +/-RBV [n=11], GLP+PIB [n=5]. At failure, all patients harbored NS5A RASs, with a mean number of 3 NSSA RASs. Interestingly, failures with GT6h/p/exe carried 4 to 5 NSSA polymorphisms possibly associated with reduced NSSA inhibitors susceptibility. All GT3b/3g/3k harbored the NSSA A30K+L31M combination. Additionally, in patients failing NS3 protease inhibitor-based therapy, combinations of NS3 RASs were detected in specific subtypes: R155Q/A156T/D168N/E and Y56H+D168V in two GT4g and one GT6q patients failing GZR/EBR, and A156F/D168V in a GT6q patient failing GLP+PIB.

Conclusions: Unusual subtypes may be overrepresented among DAA failures. In-depth characterization of these subtypes is crucial, in Africa and Asia where these subtypes are common as well as in countries of immigration from these regions. Our results emphasize the need for identification of RASs in these subtypes and their in vitro drug susceptibilities.

Persistence of Tropheryma whipplei colonisation: a longitudinal study in Italy

Anna Beltrame1, Lucia Moro1, Giorgio Zavarise2, Giada Castagna2, Chiara Piubelli1, Andrea Ragusa1, Fabio Formenti1, Francesca Perandin1, Ronaldo Silva1, Zeno Bisoffi*

1I.R.C.C.S. Sacro Cuore Don Calabria Hospital, Department of Infectious, Tropical Diseases and Microbiology, Negrar di Valpolicella, Italy, 2I.R.C.C.S. Sacro Cuore Don Calabria Hospital, Paediatrics Department, Negrar di Valpolicella, Italy

Background: Whipple disease (WD) is a rare and potentially fatal illness caused by Tropheryma whipplei (TW). TW DNA can been found in biological specimens of WD patients but also of asymptomatic carriers. Its identification in faeces, saliva, urine and blood has been described as a promising non-invasive diagnostic approach to differentiate between possible WD and colonization, but very little is known about persistence of TW. In our previous retrospective, observational study (2014-2016), 6.9% [85/1240] of faeces collected from Italians and migrants resulted positive to TW. However, no clinical information was available at that time.

Materials/methods: In September 2019 we contacted the 85 subjects whose faeces had resulted TW positive for a clinical revaluation including rt-PCR for TW in faeces, saliva, urine and blood. Subjects were to be classified as having: transient colonization (rt-PCR negative on all samples), asymptomatic colonization [no symptoms and at least one positive rt-PCR], and possible WD (symptoms with a positive rt-PCR or ≥ 2 positive rt-PCR regardless of symptoms or a single positive rt-PCR on blood).

Results: We analyzed the preliminary data of 26 (31%) subjects. The median age was 26 years, 58% were male, and 58% were migrants (most from Africa). Rt-PCR resulted negative in all samples in 9 (35%) subjects (transient colonization); 17 (65%) subjects had at least one rt-PCR positive in faeces or saliva after a median of 50 months. Blood and urine specimens were negative. Out of the 17 colonized subjects, 15 (88%) were asymptomatic and 2 (12%) reported both abdominal discomfort, chronic diarrhea and weight loss (possible WD). One subject, asymptomatic, had rt-PCR positive in both faeces and saliva (possible WB).

Conclusions: This is to our knowledge the first study to prospectively follow TW colonized subjects for such a long time. More than half of subjects are still colonized after nearly 4 years, suggesting that a long colonization or a reinfection are frequent. Combined use of TW rt-PCR allowed us to identify 3 subjects with possible WD who will undergo to more invasive procedures to confirm the diagnosis.

Abstract 4927

Efficacy of ceftolozane-tazobactam in combination with colistin against extensively drug-resistant *Pseudomonas aeruginosa* including high risk clones, in an *in vitro* pharmacodynamic model

M. Milagro Montero*, Sandra Domene Ochoa1, Carla Lopez Causape2, Brian D. Vanscoy1, Sonia Luque1, Luisa Sorli1, Ariadna Angulo1, Eduardo Padilla1, Nuria Priam1, Virginia Pomin1, Alba Rivera2, Nuria Campillo1, Santiago Grau1, Paul G. Ambrose3, Antonio Oliver1, Juan P. Horcajada1

1Hospital del Mar, Barcelona, Spain, 2Hospital Universitario Son Espases, Palma, Spain, 3Institute of Clinical Pharmacodynamics, Schenectady, United States, 4Laboratorio de Referencia de Catalunya SA, Prat de Llobregat (El), Spain, 5Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Colistin has been the only treatment available for extensively drug-resistant (XDR) *Pseudomonas aeruginosa* infections, for many years, having suboptimal results. Ceftolozane/tazobactam (C/T) is a new therapeutic option that showed good antipseudomonal activity. However, data about combinations containing C/T are scarce.

**Objectives:** To analyse the efficacy of C/T and colistin alone and combined against three XDR *P. aeruginosa* ST175 isolates with different susceptibility to C/T.

**Materials/methods:** The *in vitro* pharmacodynamic chemostat model was used to validate the effect of C/T and colistin alone and combined against three XDR *P. aeruginosa* ST175 isolates with different MIC values. All strains were colistin-susceptible. The simulated C/T dosing regimen was 2/1g every 8h by intravenous infusion over 1h. A continuous infusion of colistin was simulated to achieve free steady-state concentrations of 2mg/L. Bacterial suspension was cultured onto agar supplemented with C/T or colistin at 2-fold and 4-fold the baseline MICs to assess the effect of each regimen on less-susceptible bacterial population. Pharmacokinetic samples were validated by HPLC.

**Results:** ST175 [10-023] was C/T-susceptible with a MIC of 2mg/L showing resistance to β-lactams except C/T due to OprD inactivation and AmpC hyperproduction. ST175 [09-12] was C/T-resistant with a MIC of 8mg/L and showed a specific mutation in PBP3 associated with increased β-lactam resistance. ST175 [07-016] was C/T-resistant with a MIC of 16mg/L and produced GES-5. In the PK/PD model, the scheme of C/T at 2/1g every 8h combined with colistin effectively suppressed the bacterial growth at 24h. Additive or synergistic interactions with C/T plus colistin were observed against *P. aeruginosa* isolates, including those C/T-resistant [Figure 1]. C/T-resistant isolates were not detected in any of the strains with any schemes. The emergence of a colistin-resistant population was detected at the end of the experiment with colistin alone in all the strains. No colistin-resistant populations were detected with the combination. The simulated drug exposures achieved were considered satisfactory for all regimens.

**Conclusions:** Our study showed that the combination of C/T plus colistin improved the activity of monotherapies against XDR *P. aeruginosa* infections. Our data suggested that it may be a useful treatment of these infections and highlighted its potential role against C/T-resistant isolates.
Figure 1. In vitro chemostat experiments with three selected XDR P. aeruginosa ST175 isolates with different susceptibility levels to C/F: ST175 (10-023) with an MIC of 2 mg/ml, ST175 (09-012) with an MIC of 8 mg/ml, and ST175 (07-016) with an MIC of 16 mg/ml. Mean number of CFUs over 24 h for each P. aeruginosa isolate and antibiotic.

**Evaluation of OspC as marker for direct diagnostic of Lyme disease**

Victoria Dolange*1, Dominique Marcé1, Elisabeth Ferquel2, Stéphanie Simon1, Valérie Choumet2, Nathalie Morel1

1 Service de Pharmacologie et Immunoanalyse (SPI), CEA, INRA, Université Paris-Saclay, Gif-Sur-Yvette, France, 2 Unité Environnement et Risques Infectieux, Institut Pasteur, Paris, France

**Background:** Lyme disease is the most common tick-born infectious disease in Europe. This infection is caused by spirochetes of *Borrelia* species. Currently, laboratory diagnostics are exclusively based on serological tests. However, these tests present a lack of sensitivity, specificity and standardization due to the absence of serum antibodies in early stage, the poor representativeness of *Borrelia* strains and the detection of antibodies cross-reacting with ubiquitous antigens. A more reliable and precise test is thus needed. In this context, our objective is to develop a direct diagnostic test based on detection of circulating bacterial antigen produced by the bacteria. We focused on the outer surface proteins C (OspC), a 22kDa lipoprotein that is potentially considered as an early marker of Lyme borreliosis, according to serologic and protein skin host analysis. Nevertheless, OspC is highly variable between *Borrelia* species so to detect all OspC variants, we decided to produce monoclonal antibodies (mAbs) directed against a highly conserved OspC motif.

**Materials/methods:** Specific mAb clone were produced by immunization of BALB/c mice with synthetic peptide coupled to a carrier protein. MAb were characterized by immunoassay, western blot against recombinant proteins or *Borrelia* lysates. Their affinity (Kd) were determined by using bio-layer interferometry biosensor technology. Then, the potential of our antibodies to detect OspC was investigated on mice tissues extract and fluid. The mice were infected with different *Borrelia* species by subcutaneous inoculation. Mice tissue proteins were extracted, enriched by on beads immuno-precipitation and analyzed by western blot.

**Results:** 13 mAbs against the conserved OspC peptide were produced. During the characterization process, the mAb affinity (Kd) was determined at 9,31E-10 molar for the antibody of higher affinity, using recombinant OspC. We selected the mAbs OspC-11, allowing for instance to reach a limit of detection close to 5pg of OspC protein by Western-Blot and to detect OspC in mouse samples.

**Conclusions:** Taking into account the variability of *Borrelia* species, mAbs against conserved motif of OspC could be very useful for diagnostic of Lyme disease early stage. We plan now to evaluate the efficiency of these mAbs in more mice tissues and in clinical patient samples.

Rapid detection of OXA-23-, OXA-40- and OXA-58-mediated carbapenem resistance in Acinetobacter baumannii

Sonja Mertins*1,2, Paul G. Higgins1,2, Caroline Thunissen2, Quentin Gilleman3, Pascal Mertens3, Harald Seifert1,2, Martin Kroenke1,2, Alexander Klimka1,2

1University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research (DZIF), partner site Bonn-Cologne, Cologne, Germany, 3Coris BioConcept, Science Park CREALYS, Gembloux, Belgium

Background: Treatment of Acinetobacter baumannii infections can be extremely challenging owing to the wide distribution of multi-drug resistant strains. Of special concern is increasing resistance against carbapenems. The WHO published a global list of antibiotic-resistant priority pathogens with carbapenem-resistant A. baumannii as “priority 1” for research, discovery and development of new antibiotics. Colonization with carbapenem-resistant A. baumannii (CRAb) requires rapid action from an infection control perspective because the organism is known for its propensity for epidemic spread. Hence, there is an unmet medical need to rapidly identify CRAb to enable appropriate antimicrobial treatment and to prevent transmission.

Carbapenem-resistance in A. baumannii is mainly mediated by the acquired carbapenemases: OXA-23, OXA-40 like or OXA-58. In a “Proof-of-concept” study we have generated and selected anti-OXA-23 monoclonal antibodies (moAbs), which have been implemented in the commercially available OXA-23 K-SeT (Coris BioConcept).

Our aim was to expand the OXA-detection abilities of the OXA-23 K-SeT to include OXA-40- and OXA-58-like carbapenemases.

Materials/methods: We generated and selected specific anti-OXA-40 (n=8) and anti-OXA-58 (n=6) moAbs. Combinations of these moAbs, were analyzed in immunochromatographic test (ICT) format for their ability to detect recombinant OXA-40 or OXA-58, respectively. Antibody pairs showing specific and strong signals were chosen and implemented into single-OXA-40 and single-OXA-58 ICT-prototypes. Those ICT-prototypes were evaluated on clinical A. baumannii isolates (n=40) with well-defined carbapenem-resistance mechanisms.

Results: One set of antibody pairs specific for recombinant OXA-40 or OXA-58 were identified in ICT format, respectively. These moAbs were implemented into single-OXA ICT-prototypes. Furthermore, one anti-OXA-58 moAb (#C8), which shows cross-reactivity to OXA-40 and OXA-58 was implemented in additional single-OXA ICT-prototypes.

The evaluation of these single-OXA-40 and single-OXA-58 ICT-prototypes with CRAb isolates has demonstrated 100% specificity within 15 min.

Conclusions: Based on successful single-OXA ICT-prototype validation the development of a triple-OXA-23/40/58 ICT will be envisaged to detect more than 93 % of CRAb strains worldwide.

With this easy-to-use, rapid detection assay one can save 12-48 hours in diagnostics, which helps to treat patients earlier with appropriate antibiotics and allows immediate intervention to control transmission of CRAb.

Abstract 4932

**Patient management and indication for influenza A/B and respiratory syncytial virus Point-of-Care testing in the emergency room and possible gains by syndromic respiratory testing**

Uffe Vest Schneider*1, Mona Holm2, Didi Bang3, Randi Føns Petersen1, Shila Mortensen3, Ramona Trebbien3, Gorm Lisby2

1Rigshospitalet, København, Denmark, 2Hvidovre Hospital, Hvidovre, Denmark, 3Statens Serum Institut, København, Denmark

**Background:** Point-of-care testing (POCT) for Influenza A/B & RSV was implemented in the emergency room at all hospitals in the Capital Region of Denmark in 2018. To evaluate the implementation, we have verified indication for testing, effects on patient management and finally considered possible benefits of a syndromic testing approach on patients that are currently tested for Influenza A/B & RSV

**Materials/methods:** Patients samples from 555 patients tested by POCT between February and July 2018 were retested for 26 respiratory pathogens and the patient records were evaluated with respect to diagnosis, indication for POCT, hospitalisation time, antimicrobial therapy and readmission or death within one month of testing

**Results:** A valid indication for POCT was established for 502 (90.5%) of all patients. A positive POCT result significantly reduced median hospitalisation time (11.8 vs. 38.8 hours) and initiation of antibiotics (26.6 vs. 50.5%), whereas antiviral treatment was significantly increased (11.8 vs 1.6%). Risk of readmission or death was not significantly altered by a positive POCT result. Testing for 26 respiratory pathogens established that risk of co-infection drops by age and that POCT should be restricted to the season. A trend towards longer median hospitalization time (19.7 vs 11.8, p = 0.087) and initiation of antibiotics (36.6 vs 26.6%, p = 0.055) was established for patients positive for one or more respiratory pathogens not included in the initial POCT

**Conclusions:** POCT increases antiviral treatment and reduces hospitalisation time and initiation of antibiotics. Syndromic POCT may be beneficial in small children and outside the influenza season, decreasing hospitalization time and antibiotic use

**Presenter email address:** uffe.vest.schneider@regionh.dk
Abstract 4933

Clinical and gut microbiome characterisation of Clostridiodes difficile infection in immunosuppressed patients

Silvia Noemi Vazquez Cuesta*, Laura Villar Gomara¹, Nuria Lozano¹, Luis Alcalá¹, Mercedes Marín¹, Patricia Muñoz¹, Emilio Bouza¹, Elena Reigadas Ramirez¹

¹Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain

Abstract third-party references: On behalf of the HGUGM Microbiome Project

Background: Data on Clostridiodes difficile infection (CDI) in specific groups are necessary in order to assess the impact of health care programs and implementation of novel costly treatments targeted for specific groups. Immunosuppressed patients are particularly susceptible to C. difficile, however little is known about specific markers of recurrence (R-CDI). Our objective was precisely to assess the clinical and gut microbiome characteristics of CDI in immunosuppressed patients.

Materials/methods: We prospectively included patients who fulfilled criteria for CDI and immunosuppression (jan2019-on-going study). Informed consent was obtained for all patients included. Epidemiological, clinical data and fecal samples were collected. For microbiome analysis, the hypervariable V4 region of the 16s rRNA gene was sequenced on an Illumina Miseq platform. Mothur's bioinformatic pipeline was followed for data analysis.

Results: During the study period, 4,341 samples were sent for CDI diagnosis. 452 were positive, out of which, 135 (29.9%) were from immunosuppressed patients. Seventy-seven episodes (56 primary episodes; 16 first recurrences; 5 second recurrences) from 56 patients who consented to their inclusion. Median age was 61.5 years and 55.4% were females. Immunosuppression was due only to underlying disease in 61.5%, in 29.9% due to medication, and 19.6% due to both. The most frequent underlying diseases were cardiological (50.0%), endocrine (37.5%), solid tumors (33.9%), and hematological (32.1%). Severity of CDI episodes was mild-moderate (63.6%), severe (18.2%) and severe complicated (7.3%). Recurrence occurred in 31.0%, overall mortality was 3.5% and CDI-related mortality was 1.8%. Female sex was an independent risk factor for R-CDI (p=0.046). Regarding microbiota analysis, the most predominant phyla were: Firmicutes (47.7%), Bacteroidetes (30.4%) and Proteobacteria (13.7%). We found no significant difference in alpha-diversity, beta-diversity or abundance of specific microorganism groups regarding the cause of immunosuppression or the presence of R-CDI.

Conclusions: One third of CDI patients had immunosuppression condition. A significant proportion had a severe or severe-complicated CDI and recurrence rate was high. Female sex was the only independent risk factors for R-CDI in this population. We could not establish any microbiota marker for R-CDI in this population. Immunosuppressed CDI patients showed an altered microbiota composition equiparable to that of other CDI patients.

Abstract 4934

A rapid adenosine triphosphate bioluminescence-based assay for predicting antibiotic combinations against dividing and non-dividing live carbapenem-resistant Enterobacteriaceae

Yiying Cai*1,2, Nasren Begam1, Nazira Fauzi1, Hui Sian Fiona Wong1, Tze-Peng Lim1,2,4, Jocelyn Teo1,5, Thuan Tong Tan1, James Heng Chiak Sim1, Andrea Kwa1,4,6

1Singapore General Hospital, Singapore, Singapore, 2National University of Singapore, Singapore, Singapore, 3SingHealth Duke-NUS Pathology ACP, Singapore, Singapore, 4SingHealth Duke-NUS Medicine ACP, Singapore, Singapore, 5National University of Singapore and National University Health System, Saw Swee Hock School of Public Health, Singapore, Singapore, 6Duke-NUS Medical School, Singapore, Singapore

Background: Non-dividing bacteria persisters, which cannot be detected by viable plating assays, have been implicated in infection relapse and development of antibiotic resistance. Persisters are particularly problematic in CRE, as pan-drug-resistant Enterobacteriaceae can develop if persisters are not eradicated. We have previously demonstrated that flow cytometry (FCM) can detect dividing and non-dividing live cells, and can hence identify effective antibiotic combinations against CRE persisters, but require specialised equipment and laborious staining. We developed a rapid ATP bioluminescence-based assay to screen and identify effective antibiotic combinations against dividing and non-dividing live CRE in FCM.

Materials/methods: To develop the assay, we tested 19 CREs (2 bla_{KPC}, 4 bla_{NDM}, 4 bla_{OXA48}, 4 co-producers, 5 non-producers) against 74 single and two-antibiotic combinations at clinically achievable concentrations. Bacteria (10^5 CFU/ml) were incubated with the antibiotic(s) at 35°C. At 24h, samples were obtained for: (a) ATP bioluminescence after removal of extracellular ATP using apyrase (1U/ml), and (b) FCM analysis using propidium iodide to differentiate live/dead cells, SYTO-62 to visualise nucleic acid, and calibrated beads for enumeration. Receiver operating characteristic (ROC) curves were used to determine optimal bioluminescence thresholds (TRLU) for predicting combinations that were (a) at least inhibitory, (b) ≥1log_{10} bacteria/ml reduction (≥90% kill), (c) ≥2log_{10} bacteria/ml reduction (≥99% kill) in FCM. Prospective validation of the established TRLU was performed using 10 additional CREs.

Results: A total of 1,406 bacteria-drug combinations was tested [Figure 1]. As shown, high accuracy ranging 80%–91% was observed for all three TRLU. The predictive accuracy was highest in determining inhibitory and non-inhibitory antibiotic combinations (TRLU=6.67; accuracy=91%, sensitivity=91%, specificity=90%). Upon external validation, the ATP bioluminescence assay distinguished combinations that were at least inhibitory, ≥1log_{10} bacteria/ml reduction [≥90% kill], ≥2log_{10} bacteria/ml reduction [≥99% kill] in FCM. Prospective validation of the established TRLU was performed using 10 additional CREs.

Conclusions: Our ATP bioluminescence assay can be employed to screen multiple antibiotic combinations to identify useful combinations against dividing and non-dividing live CRE within 24h. It may be employed to guide the timely selection of effective antibiotic combinations.

Abstract 4937

**Rifaximin leads to eradication of KPC *Klebsiella pneumoniae* gut colonisation in a mice model**

Eleni Xenofontos¹, Georgios Renieris², Dionyssia-Irene Droggiti², Kalliopi Synodinou², Labros Sabrakos², Evangelos Giamarellos-Bourboulis*²

¹Department of Internal Medicine, Limassol General Hospital, Limassol, Cyprus, ²4th Department of Internal Medicine, National and Kapodistrian University of Athens, Medical School, Athens, Greece

**Background:** Current knowledge suggests that infection by carbapenem-resistant enterobacteria (CRE) is preceded by gut colonization. It may be hypothesized that eradication of colonization by non-absorbable antibiotics may protect the patient. Following previous in vitro data (Xenofontos E, et al. ECCMID 2018; abstract 00721) on the considerable effect of rifaximin on KPC, eradication of KPC gut colonization by rifaximin was investigated in an experimental model.

**Materials/methods:** At first stage, we developed a model of gut colonization by *Klebsiella pneumoniae*-producing carbapenemase (KPC); 40 C57Bl6 mice were pre-treated with saline, oral 40mg/kg omeprazole or subcutaneous ampicillin 50mg/kg. After 5 days, mice were fed with 10⁸ cfu KPC for 7 days. Stool samples were collected for measurement of KPC growth. At second stage, 12 mice with established KPC gut colonization received orally three times daily for 7 consecutive days either rifaximin 60mg/kg dissolved in 8% bile or vehicle. On days 0, 3 and 7 stool samples were collected; mice were sacrificed for determination of tissue outgrowth.

**Results:** Pretreatment with ampicillin led to greater KPC stool outgrowth after 3 and 7 days compared with saline (3.89 ± 0.67 vs 1.35 ± 0.21 cfu/ml, p < 0.0001 and 2.27 ± 0.45 vs 1.29 ± 0.17 cfu/ml, p: 0.019 respectively). Pretreatment with omeprazole did not affect KPC growth. Rifaximin treated mice had significantly lower bacterial load in stool and gut tissue (Figure).

**Conclusions:** Development of experimental gut colonization by KPC mandates ampicillin pre-treatment. Oral rifaximin leads to eradication of gut colonization.

Clinical, microbiological and molecular studies of invasive pulmonary aspergillosis caused by *Aspergillus lentulus* in China

Shu-Ying Yu, Menglan Zhou, Yingchun Xu

1Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China

**Background:** Here is the first study aimed at clinical, microbiological and molecular characteristics of *Aspergillus lentulus* from invasive aspergillosis (IA) patients in China.

**Materials/methods:** A panel of six non-duplicate *A. lentulus* isolates recovered from respiratory tract of patients with proven or probable IA under the China Hospital Invasive Fungal Surveillance Net (CHIF-NET) program during August 2016 to July 2017. Accurate identification and phylogenetic analysis of all the isolates were based on multi-locus sequence typing (MLST) of five genes. Seven microsatellite markers employed for *A. lentulus* genotyping. The identification of all the isolates were further explored using two MALDI-TOF MS systems. The in vitro susceptibility to nine antifungal drugs was determined by CLSI M27-A3 broth microdilution methodology.

**Results:** A total of six patients in our study were diagnosed as proven or probable IA caused by *A. lentulus*, associated with fatal outcome. Immunocompromised state, prior antifungal therapy and ICU hospitalization were obvious risk factors for invasive *A. lentulus* infection. Minor phenotypic characteristics were observed in *A. lentulus* isolates including slowly growth, reduced sporulation and inability of growth at 48°C, compared with *A. fumigatus*. ITS sequences were incompetent for distinguishing *A. lentulus* and *A. fumigatus*, while benA, CaM and rod A sequences were reliable for distinction to the species level. Phylogenetic analysis further confirmed that ITS region had little variation of *Aspergillus section Fumigati* while benA gene had highest intraspecific discrimination among the four gene. Microsatellite typing results showed that chromosome 1, 3, 5 and 6b were available for *A. lentulus*. All the *A. lentulus* isolates in our study were showed in vitro resistance to multiple drugs including amphotericin B (MIC range 4 to 8 μg/ml), itraconazole (MIC 2 μg/ml), voriconazole (MIC range 8 to 16 μg/ml) and posaconazole (MIC range 0.5 to 1 μg/ml). While the MEC range for caspofungin, micafungin and anidulafungin were 0.03 to 0.25, ≤0.08 to 0.15 and ≤0.08 μg/ml, which were classified as wild type against echinocandins.

**Conclusions:** This study points that *A. lentulus* as an emerging fatal causative agent worldwide should be concerned by clinicians and laboratories in the future.

Abstract 4940

Bioinformatic fake news: the important but under-appreciated caveats of identifying resistance genes from whole genome sequencing data

Timothy James Davies1*, Anna Sheppard1, Jeremy Swann1, Nicole Stoesser1, Matthew Ellington1, Neil Woodford2, Tim Peto1, Derrick Crook1, Muna Anjum3, A. Sarah Walker1

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2Public Health England, Antimicrobial Resistance and Hospital Associated Infections Reference Unit, London, United Kingdom, 3Animal and Plant Health Agency, Bacteriology, London, United Kingdom

Background: Whole-genome sequencing (WGS) could play an important role in the surveillance of antimicrobial resistance, enabling high-throughput, cost-effective identification of high-risk transmissible resistance genes [TRGs]. However, multiple bioinformatic methods for TRG identification are in common use, and the impact of bioinformatic method on reported resistance genotypes remains unclear.

Materials/methods: We identified TRGs for five antimicrobial classes in 1818 UK Escherichia coli isolates (1321 human bloodstream infection isolates and 497 pig commensal isolates) using four widely-used bioinformatic algorithms (ABRicate, ARIBA, KmerResistance, SRST2) and a single (ResFinder) database. Discrepancies between algorithms were quantified and the causes of the most common patterns were investigated. We assessed whether benchmarking against phenotype was sufficiently discriminatory to identify true genotypes for discrepancies.

Results: There was significant discordance between the four approaches, with allelic variants in reported genotypes being different for at least one gene for 934/1818 (51%) isolates. Patterns of discordance were complex, with no single method responsible for most discrepancies (Figure). The extent of discrepancy was strongly associated with particular genes, being worst for aminoglycoside and sulfonamide resistance genes (p<0.001). However, much of the difference was artefactual. All discrepancies in 508/934 (54%) isolates were explained by two common deterministic issues arising as a result of different bioinformatic approaches. These were: programs identifying "phantom" additional alleles as an artefact of clustering approaches (encountered in 660/934 [71%] discrepant isolates), and homologous alleles differing in length being favored by different algorithms, where best match is chosen by either optimal alignment score or percentage identity (encountered in 399/934 [43%] discrepant isolates). In addition to these artefactual causes of discrepancy, algorithms also performed differently in several other scenarios, including differentiating multiple related alleles in the same isolate and identifying low coverage alleles. Pheno-type was a poor benchmark, with difference in genotypes only expecting to modify phenotype in 353/934 (38%) discrepancies.

Conclusions: Commonly used bioinformatic approaches for resistance genotyping led to highly discordant results in the specific alleles that were identified from a standard resistance database. Over half of these discrepancies were artefactual, being due to algorithm-specific assumptions. This highlights the limitations of current bioinformatic approaches to TRG identification, and has important implications for resistance surveillance.

Bacterial consortium: the evolution of the Faecal Microbiota Transplantation (FMT)

Gianluca Quaranta*1, Giovanni Fancello1, Rosalia Graffeo1, Gianluca Ianiro1, Giovanni Cammarota1, Maurizio Sanguinetti1, Luca Masucci1

1Università Cattolica del Sacro Cuore - Fondazione Policlinico A. Gemelli, Rome, Italy

Background: Fecal microbiota transplantation (FMT) consists of infusion of feces from a donor to a recipient patient in order to restore the resident microbial flora. FMT has shown to be a valid option for Clostridium difficile infections (CDI). However, this approach presents technical, logistical and bureaucratic criticalities. Our aim was to evaluate the therapeutic efficacy, of a synthetic bacterial suspension, defined “Bacterial Consortium” infused in the colon of CDI patients. The suspension was composed by 15 microbial species isolated from the feces of healthy donors by culturomics protocols. Each strain was evaluated on an antibiotic susceptibility/resistance profile. Efficacy of the treatment was assessed both clinically and by metagenomics typing.

Materials/methods: “Bacterial Consortium” suspension (250 ml) was prepared on the same day of the infusion using the 15 selected strains. Fecal samples of two recipient patients were collected before and after infusion. DNA samples obtained from feces at different time point (t0, 7, 15, 30 and 90 days after infusion) were analyzed using the KIT 16S r RNA Miseq (ILLUMINA).

Results: Before infusion patient 1 showed an intestinal microbiota dominated by the Phylum Bacteroidetes. After 7 days Bacteroidetes decreased, followed in parallel by an implementation of Firmicutes and Verrucomicrobia. In the subsequent time-points, a stabilization of the intestinal microbiota, in which Bacteroidetes and Firmicutes increased and the Proteobacteria fall in minimum values, was observed. Patient 2, before infusion, showed a strong abundance of Proteobacteria, Firmicutes and a significant deficiency of Bacteroidetes and Verrucomicrobia. 7 days after infusion Proteobacteria strongly decreased, while Bacteroidetes increased to almost 50% accompanied by an implementation of Verrucomicrobia. 90 days after the infusion microbiota was stabilized with a prevalence of Bacteroidetes and Firmicutes.

Conclusions: Metagenomics revealed the presence both of the cultivated and infused bacteria and the “awakening” by microbial species absent at time t0 and present after the infusion. These evidences suggest a stimulatory action by “Bacterial Consortium” on the microbiota damaged by C.difficile. The infusion of selected bacteria, appropriately screened, would act as a trigger factor for mechanism of “bacterial repopulation”. This strategy increases biosafety and may allow to bypass FMT critical points.

Staphylococcus aureus bacteraemia during a 2-year period in a tertiary university hospital: outcome and correlations to host- and pathogen-related characteristics

Hannah Wächter1, Erdal Yörük1, Dennis Görlich2, Karsten Becker1, Barbara C. Kahl1

1University Hospital Münster, Medical Microbiology, Muenster, Germany, 2University Hospital Münster, Institute of Biometry and Clinical Research, Muenster, Germany

Background: Staphylococcus aureus bacteremia is associated with a high mortality rate. We performed a retrospective analysis to assess the number and outcome of patients with S. aureus bacteremia in our tertiary University Hospital. Furthermore, we investigated virulence factors, with a possible impact on outcome.

Materials/methods: From May 2013 until July 2015, all patients with S. aureus bacteremia and complete clinical information were included in this study. Data about mortality, fever, leukocytes, CRP and antibiotic therapy were collected and transferred to SPSS. Respective S. aureus isolates were thawed and characterized by spa-typing, single and multiplex PCR to assess agr-types, pvl, etA/B/D, tsst, edinA/B/C, sea-e and seg-j. We performed a static biofilm assay to measure biofilm formation as well as a FRET assay for the quantification of nuclease activity.

Results: 178 patients with S. aureus bacteremia were included (41.6% female, mean age 58.73 years) with a mortality rate of 25%. In 19 patients (11%), no focus was identified. In most cases, bacteremia was catheter related (71 patients, 40%), due to abscess or cellulitis (23 patients, 13%), pneumonia (22 patients, 12%), or endocarditis (16 patients, 9%). 112 patients (63%) presented with fever >38°C, 159 patients (89%) with elevated CRP levels, 77 patients (43%) with increased and 20 (11%) with decreased leukocytes. Patients with S. aureus-directed antibiotic therapy died less likely (p=0.014). The highest mortality was observed for patients with S. aureus pneumonia and bone and joint infections (36%). Elder patients died more likely, had higher leukocyte and CRP values and were more often infected by MRSA. The most prevalent clonal complexes were CC084 (38 patients, 21%), CC012 (21 patients, 12%), CC015 (19 patients, 11%), CC005 (18 patients, 10%) and CC068/080 (11 patients, 6%). Eighteen patients were infected by MRSA (10%). Biofilm formation of isolates was associated with CCs and the absence of seh (p=0.021) or the presence of sec (p=0.018). Higher nuclease activity of isolates was associated with female gender (p=0.008) and the absence of see (p=0.042).

Conclusions: Our data revealed that bacteremia occurred often with a high rate of mortality, which was associated with age, number of leukocytes, antibiotic therapy and agr-type.

Abstract 4946

Clinical validation of the BD CTGCTV2 for BD MAX system assay in male urine specimens
Barbara Van Der Pol*, Edith Torres-Chavolla1, Salma Kodsi2, Charles K. Cooper3, Thomas Davis3, Kenneth H Fife4, Stephanie Taylor5, Michael Augenbraun6, Laura Bachmann7, Charlotte Gaydos8

1University of Alabama at Birmingham, Birmingham, United States, 2BD Lifesciences, Sparks, United States, 3Eskanazi Hospital, Indianapolis, United States, 4Indiana University School of Medicine, Indianapolis, United States, 5Louisiana State University Health Sciences Center, New Orleans, United States, 6SUNY Downstate Medical Center, Brooklyn, United States, 7Wake Forest Health Center, Winston, United States, 8Johns Hopkins School of Medicine, Baltimore, United States

Background: As rates of treatable sexually transmitted infections (STI) continue to increase globally, simple, accurate tests for screening and diagnostics are needed. In addition to chlamydia and gonorrhea, trichomoniasis is known to cause urethritis in men and asymptomatic carriage of trichomoniasis is known to be responsible for sexual transmission of this pathogen to women. Therefore, assays that detect all 3 pathogens simultaneously support the goal of reducing the burden of STI at the population level. One such platform is the BD MAX™ System using the BD CTGCTV2 assay (pending CE Marking; Not available for sale in Europe/EEA). Here we describe the performance of the MAX assay when using first catch urine (FCU) from men.

Materials/methods: Men provided an FCU that was aliquoted into the transport device used for the Hologic Aptima® AC2 and ATV assays, the BD ProbeTec™ CTQx, GCQx and TVQx assays and the Cepheid Xpert® CT/NG and TV assays. At least 2 positive results from the 3 comparator assays were required to classify men as infected.

Results: Specimens were obtained from 1,159 men. Positivity rates for chlamydia, gonorrhea and trichomoniasis were 13.6, 10.8, and 4.4%, respectively. Sensitivity estimates were 96.7% (95% CI 92.6-98.6%), 99.2% (95% CI 95.5-99.9%), and 97.9% (95% CI 89.1-99.6%) for chlamydia, gonorrhea, and trichomoniasis, respectively. All specificity estimates were ≥ 99.4%. The BD CTGCTV2 assay has dual gonorrhea targets in order to optimize specificity; both are required to give a signal in order for the result to be positive. This design did not reduce the number of positives (no impact on sensitivity) since 122/123 infected men had BD MAX GC positive reactions with both targets. The PPV based on observed GC prevalence (10.8%) was 99.2% (95.6-99.9%).

Conclusions: The BD CTGCTV2 assay has high sensitivity and specificity for detection of chlamydia, gonorrhea and trichomoniasis from FCU. Adoption of this assay can i) support local testing where smaller batch sizes increase efficiency, ii) identify asymptomatic trichomoniasis infections and thus reduce the potential for this STI to be transmitted to sex partners, and iii) ensure the specificity of positive gonorrhea results, potentially eliminating the need for confirmatory testing.

Abstract 4948

Strongiloidiasis in patients with Chagas disease in Barcelona

Eva Dopico*, Luis Solsona1, Mercedes Aguilar1, Yolanda Rando-Matos2, Laura Guerrero3, Guillem López De Egea1, Juanjo Mascort4, Elena Sulleiro5

1Bellvitge University Hospital, Laboratori Clínic Territorial Metropolitana Sud (LCTMS), L’Hospitalet de Llobregat, Spain, 2Equip d’Atenció Primària Florida Nord, Institut Català de la Salut (ICS), L’Hospitalet de Llobregat, Spain, 3Universitat de Barcelona, Facultat de Biologia, Barcelona, Spain, 4Equip d’Atenció Primària Florida Sud, Institut Català de la Salut (ICS), L’Hospitalet de Llobregat, Spain, 5Vall d’Hebron University Hospital, Barcelona, Spain

Background: Chagas disease (CD) and strongiloidiasis are neglected tropical diseases according to WHO and they can result in chronic infections even lasting throughout life with high morbidity and mortality. Recent studies in Barcelona have shown a significant association between CD and strongiloidiasis so, it is recommended to perform Strongyloides stercoralis serology in people with CD.

The aim of this study was to evaluate the implementation of a systematic program of screening of strongiloidiasis in CD patients attending Primary care centres in the Southern Metropolitan Area of Barcelona.

Materials/methods: This study was carried out in patients attending Primary care centres in the Southern Metropolitan Area of Barcelona. This area with approximately 5% of Latin American population has the highest number of people with CD in Catalonia.

In June 2018, a systematic program was implemented performing Strongyloides stercoralis serology to all patients with T. cruzi positive serology by two different techniques or antigens according to WHO recommendations for CD diagnosis. The tests used for detection of T. cruzi antibodies were BIOFLASHChagas® using recombinant antigens and Ortho®T.cruzi Elisa Test System with native antigens. The IgG anti S. stercoralis was carried out with Strongyloides stercoralis serum Microwell ELISA, IVC® or EUROINMUN Anti-Strongyloides ELISA (IgG). The period of study was from June 2018 to October 2019.

Results: Of a total of 2337 patients tested for T. cruzi antibodies, 101 (4.41%) were diagnosed with CD. S. stercoralis serology was positive in 20 patients (19.80%) and indeterminate in 4 (3.96 %). All the cases were adults with a mean age of 40.4 (SD 8.9). Out of patients with CD 78% were women. This is due to the fact that a CD screening program is carried out in Latin American pregnant women.

The countries of origin of patients with Strongyloides stercoralis positive serology related to the total number of CD patients were: Bolivia [11/68], Paraguay [1/3], El Salvador [1/2], Honduras [0/1], Colombia [0/1], Ecuador [0/1] and country not recovered [7/25].

Conclusions: Strongyloides stercoralis serology should be performed in all patients with CD attending Primary care centres due to the high prevalence of co-infection, around 20%.

K-mer based prediction of *Clostridioides difficile* ribotypes and relatedness
Matthew Moore*1, David Eyre2

*1University of Oxford, Nuffield Department of Health, Oxford, United Kingdom, *2University of Oxford, Nuffield Department of Clinical Medicine, Oxford, United Kingdom

**Background:** Comparative analysis of *Clostridioides difficile* whole-genome sequencing (WGS) data enables fine scaled investigation of transmission and is increasingly becoming part of routine surveillance. However, these analyses are constrained by the computational requirements of the large volumes of data involved. By decomposing WGS reads or assemblies into k-mers and using the dimensionality reduction technique MinHash, it’s possible to rapidly approximate genomic distances without alignment.

**Materials/methods:** We have assessed the performance of MinHash, as implemented by sourmash, in predicting single nucleotide differences between genomes (SNPs) and *C. difficile* ribotypes (RTs). Genomes with known ribotypes (n = 3,937) were split into a training set (2,937) and test set (1,000) randomly. The training set was used to construct a sourmash index against which genomes from the test set were compared. If the closest 5 genomes in the index had the same ribotype this was taken to predict the searched genome’s ribotype. A random subset of *C. difficile* genomes (n = 2084) were compared pairwise with sourmash and MinHash distance thresholds tested for performance against SNP cut-offs, e.g. ≤10 SNPs. Further, 2000 simulated genomes were generated with SNPs, indels and sequencing errors to test sourmash performance with ideal data.

**Results:** Using our MinHash ribotype index, predicted ribotypes were correct in 780/1000 (78%) genomes, incorrect in 20 (2%), and indeterminant in 200 (20%, in these the closest matching genomes’ ribotypes differed). Relaxing the classifier to 4/5 closest matches with the same RT improved the correct predictions to 87%. For a set of 2084 diverse *C. difficile* genomes (0 – 168,519 SNPs different), using sourmash to screen for closely related genomes, at a sensitivity of 95% for pairs ≤10 SNPs, sourmash reduced the number of pairs from 2,170,486 overall to 117,356, i.e. by 94.6%, with a positive predictive value of 0.45. Increasing the MinHash sketch size above 2000 produced minimal performance improvement.

**Conclusions:** Using MinHash it’s possible to subsample genome k-mer hashes and use them to approximate small genomic differences within minutes, significantly reducing the search space for further analysis. By constructing a sourmash index of genomes with known ribotypes, ribotypes can be predicted from WGS data.

Abstract 4950

**Food and clinical human isolates of Klebsiella pneumoniae: is there correlation between multidrug resistance and biofilm formation capacity?**

Dafne Díaz-Jiménez¹, Andrea Muras², Javier Fernández², Ana Parga², Luz Leston¹, Ana María Otero², Azucena Mora Gutiérrez*¹

¹University of Santiago de Compostela, Facultade de Veterinaria, Campus Lugo, Lugo, Spain, ²University of Santiago de Compostela, Facultade de Bioxía-CIBUS, Santiago de Compostela, Spain, ³Hospital Universitario Central de Asturias [HUCA], Instituto de Investigación del Principado de Asturias [ISPA], Oviedo, Spain

**Background:** Klebsiella pneumoniae is an opportunistic pathogen implicated in nosocomial and community infections. On the other hand, food production animals have been identified as the main cause of the antimicrobial-resistance increase. Biofilm formation is involved in the colonization and environmental persistence of many bacterial pathogenic species and constitutes an unspecific mechanism of resistance to antibiotic treatment.

**Materials/methods:** A collection of 47 carbapenemase- and/or extended-spectrum-β-lactamase (ESBL)-producing K. pneumoniae recovered in northwest Spain (2016-2019), 28 from poultry meat and 19 from human infections, were characterized by PCR (bla and mcr genes), MLST and PFGE. Antimicrobial susceptibility testing was conducted by disc diffusion assay. MICs for colistin were manually obtained by broth microdilution for those suspected colonies. All results were interpreted according to CLSI guidelines. Biofilm formation was determined in the Active Attachment biofilm model using glass coverslips in LB culture medium under aerobic conditions and quantified by the Crystal Violet stain method after 24-h incubation.

**Results:** The 28 meat isolates were MDR showing the highest resistances to ampicillin (100%), cefotaxime (100%), fluoroquinolones (89.3%) and sulfamethoxazole-trimethoprim (82.1%). The ESBL typing revealed that 13 isolates were CTX-M-15, being eight of those also positive for SHV-28. Eight of the 11 STs identified within the meat isolates were previously reported in human isolates: ST15, ST45, ST111, ST147, ST307, ST627, ST966 and ST1086. Among the 19 K. pneumoniae from human clinical samples, 17 were OXA-48 and 84.2% MDR with the highest resistance rates to ampicillin (100%), amoxicillin-clavulanic acid (84.2%) and fluoroquinolones (84.2%). Eleven of the 47 K. pneumoniae were colistin-resistant, but only one human SHV-28/CTX-M-15 isolate carried the plasmid-mediated colistin resistance gene mcr-1. PFGE showed high heterogeneity within the macrorestriction profiles of the same STs. Likewise, the biofilm test revealed high variability even for isolates clustering with >85% identity in the PFGE comparison. Of the 47 K. pneumoniae, 10.6% were strong biofilm producers (five meat isolates), 46.8% moderate and 42.6% weak (Figure 1).

**Conclusions:** Poultry meat and clinical human MDR K. pneumoniae isolates showed high phenotypic and molecular variability even within the same STs. Moreover, we found no correlation between multiresistance and the biofilm formation capacity.

Abstract 4952

Antibiotic consumption in very low birth weight neonates on neonatal intensive care units in Germany: a longitudinal study 3 years of national surveillance

Florian Salm1,2, Tobias Kramer1,**, Frank Schwab1,2, Michael Behnke1,2, Petra Gastmeier1,2, Christine Geffers1,2, Brar Piening3,4

1Charité Universitätsmedizin Berlin, National Reference Center for the Surveillance of Nosocomial Infections, Berlin, Germany, 2Charité Universitätsmedizin Berlin, Institute for hygiene and environmental medicine, Berlin, Germany, 3Charité – Universitätsmedizin Berlin, National Reference Center for the Surveillance of Nosocomial Infections, Berlin, Germany, 4Charité – Universitätsmedizin Berlin, Institute for Hygiene and Environmental Medicine, Berlin, Germany

Background: Antibiotic consumption is high in very low birth weight neonates (VLBW). Surveillance of antibiotic consumption is difficult in the pediatric patient population. Due to great variance of weight and dosing in these patients surveillance systems based on defined and/or recommend daily doses are inadequate. Days of treatment (DOT) are an alternative for surveillance of antibiotic consumption.

The objective of this study was to implement and evaluate the first years of a national surveillance system for consumption of antibiotics on NICUs

Materials/methods: The national surveillance system for neonates (NEO-KISS) is almost universally used by neonatal intensive care units (NICU). NICUs in Germany. In those centers all VLBW newborns with a birthweight under 1500 gram are under surveillance. For every patient under surveillance, DOT with systemic antibiotics are assessed on daily basis. We introduced the antibiotic utilization rate as a new variable. It is calculated as the quotient of total patient days at which systemically effective antibiotics (total and per substance) are administered and the total number of patient days of the department multiplied by one hundred. The antibiotic utilization rate describes the proportion of patient days in percent on which systematic antibiotics were used.

Results: Between 2013 and 2015 data on 41,569 VLBW infants from 231 neonatal intensive care units were analyzed. In total, 1,463,897 patient days were under surveillance [median 31 days per patient; IQR 21-41]. Overall 406,120 days of antibiotic treatment were recorded.

In total 75.2% of VLBW infants received antibiotics during their surveillance period. This varied greatly. In patients with a birthweight of less than 500g birthweight 90.7% received antibiotics, while it was 89% in patients with a birthweight between 500g and 999g. In patients with a birthweight higher than 999g but less then 1500g antibiotics were prescribed to 65%.

In median 1.88 (IQR 1.74-2.03) different antibiotic agents were used per antibiotic day per patient.

Conclusions: Surveillance of antibiotic consumption is an essential part of continuously improving prescription practices. Surveillance with this module is feasible and was successfully implemented into daily routine of neonatal intensive care units.

Herpes simplex virus resistance testing: an automated interpretation platform linking genotype to phenotype

Eileen Gallagher*, David Bibby1, David Williams1, Jean L. Mbisa1

1Public Health England, London, United Kingdom

Background: The pol and tk genes of Herpes simplex virus (HSV) types 1 and 2 comprise the viral targets of currently prescribed treatments for HSV infection – aciclovir, cidofovir and foscarnet. The number of indel and substitution mutations within these genes conferring antitherpetic resistance is large and ever-growing, as is the list of natural polymorphisms.

At Public Health England (PHE), we provide genotypic resistance testing to UK hospitals to assist in guiding clinical management of acute and chronic HSV infections. Increasing demands upon this service have necessitated automation of sequence analysis and interpretation.

Materials/methods: We have created a web-browser-based application and database allowing automated analysis of HSV tk and pol gene sequencing, to support genotypic resistance assays.

In brief, FASTA files are uploaded to a web application, implemented using Flask framework in Python programming language. Built-in subprocesses call an analysis script that aligns sequences to reference genes, and outputs a variant file in the variant call format (VCF). Each VCF record is compared to a database of variants, linked to phenotypic resistance data, and a list of the relevant references. Collated interpretation data is output in text file reports.

Variant, sequence, sample, and analysis information are passed to a dedicated SQLite database via SQLAlchemy, designed to ensure secure and reliable storage, with minimal chance for incorporation of errors and data corruption. The database also allows novel variants to be uploaded and linked to phenotypic data produced by PHE’s culture-based assays.

Results: Automated sequence analysis and storage ensures that sequences are securely, efficiently and accurately processed, and reports generated. Version control of interpretation algorithms and variant databases facilitates compliance with quality management policies, as well as re-analysis of stored sequences. The linked variant and phenotyping databases allow a wide range of sequence-variant-resistance queries, helping with interpretation of the antiviral susceptibility of clinical isolates.

Conclusions: This web application and sequence-variant-phenotype database assists scientists in the analysis of HSV tk and pol gene sequences, enables efficient, repeatable, traceable and reliable result generation and storage, and permits a wide range of queries to help with interpretation of novel variants to answer clinical and research questions.

Abstract 4955

**Diagnosis of cutaneous leishmaniasis through shotgun metagenomics**

Cécile Angebault*1,2, Charlotte Bernigaud1,2, Françoise Foulet1, Tu Anh Duong1, Demontant Vanessa1, Laurence Lachaud1, Christophe Rodriguez1,2, Françoise Botterel1,2

1Hôpital Henri-Mondor Ap-Hp, Créteil, France, 2Faculté de Médecine de Créteil, Créteil, France, 3Centre Hospitalier Universitaire de Montpellier, Montpellier, France

**Background:** Cutaneous leishmaniasis (CL) is a vector-borne disease endemic in large tropical or subtropical areas. Improving its diagnosis (especially species identification) is important as CL lesions can vary, mimic other tropical diseases and as their treatment is species-driven. We compared shotgun-metagenomics (SM) with microscopic examination (ME) and PCR-based methods for CL diagnosis.

**Materials/methods:** From October 2018 to 2019, all patients seen at Mondor Dermatological Center (Creteil, France) with lesions evocative for CL were biopsied. ME (RAL 555) and rt-PCR targeting 18S-rRNA were performed. When positive, *Leishmania* species were identified through Sanger *cytb* sequencing (Foulet. JCM. 2007). SM was performed on positive biopsies. DNA/RNA libraries were prepared on NextSeq500 (Illumina). SM data were analyzed using MetaMIC® which identified viral, bacterial, fungal and parasitic genomes. Results of ME, PCR and SM were compared in terms of *Leishmania* detection and species identification. All CL were declared to the reference center (Montpellier).

**Results:** Over 1 year, 34 patients underwent skin biopsies for CL diagnosis, 7 were positive on ME and 3 using PCR. The median age of CL patients was 42.7 years and the M/F ratio 1.2. All patients visited endemic areas: Northern (n=6) or Sub-Saharan (n=4) Africa, India (n=1), Colombia (n=1), Israel (n=1). All patients had multiple-site lesions, except three. *Cytb* sequencing allowed the identification of 8 *L. major*, 1 *L. brasilienzis* and was non-contributory in 4 cases. SM was performed in 11/13 cases (ongoing, n=2). In 10 cases, *Leishmania* were identified at species level with a better discriminating power of RNA sequences. SM results were concordant with *cytb* sequencing but provided 2 additional species identification (*L. major*). In one case, no parasitic DNA/RNA sequences were detected. The patient presented an unusual keloid lesion persistent after meglumine antimoniate injections. Histological diagnosis was unavailable and the *Leishmania* DNA load was very low in rt-PCR. No other pathogens were identified in any of the cases using SM.

**Conclusions:** SM is a powerful tool for CL diagnosis which gives better results than Sanger sequencing for species identification. The availability of this additional tool in the diagnosis of leishmaniasis could also be an opportunity for strain genotyping.

Abstract 4962

Mycoplasma genitalium resistance against antibiotics in a Berlin MSM cohort tested with the Allplex MG & AziR Assay and Allplex MG & MoxiR Assay

Martin Obermeier*, Stefan Breuer1, Robert Ehret1

1MVZ Medizinisches Infektiologiezentrum Berlin, Berlin, Germany

Background: Due to high rates of sexual transmitted infections [STI] reported especially in the MSM-community there is a rise in awareness and in testing. Mycoplasma genitalium (MG) is one important cause of non-gonococcal urethritis and emerging antibiotics resistance is a major concern. Standardized NAT tests are favored for this hard to culture bacterium in routine diagnostics. We tested here the Allplex MG&AziR and the new moxifloxacin-resistance MoxiR Assay [Seegene] on MG positive samples.

Materials/methods: Screening MSM for MG from urethral/anal swabs or urine was performed with the Hologic Panther system [Aptima Mycoplasma genitalium]. 163 MG positive samples were then tested for macrolide resistance with the MG&AziR Assay and 48 of those tested for moxifloxacin resistance. The AziR Assay detects and differentiates the SNP mutations A2058C/G/T and A2059C/G/T of the 23S rRNA gene region V of MG and the MoxiR Assay detects mutations G259A/C/T, G248A/T and A247C in the ParC gene.

Results: 68.1% (N=111/163) and 70.8% (34/48) of MG positive screened samples were also positive in the MG&AziR and MoxiR Assay, respectively. In a very high proportion of these samples 82.9% (N=92) Azithromycin resistance mutations could be detected. A2059G was the mutation detected with the highest frequency (78.3%; N=72) followed by A2058G (18.5%; N=17). Three samples had an A2058T mutation (3.3%). No sample showed an A2058C or A2059C/T mutation. Six samples additionally showed Moxifloxacin resistance (3xG248A each 2xG259A and G248T). For one sample only a Moxifloxacin resistance mutation was detected. Overall a Moxifloxacin resistance rate of 20.6% was detected.

Conclusions: Due to the very high sensitivity of the TMA test not all of the MG positive pretested samples were positive with the Allplex assay. 78.3% of resistant samples showed the A2059G mutation leading to resistance against Azithromycin and Josamycin. As access to Pristinamycin is limited in Germany the usual second line option is Moxifloxacin. 4 of 25 sample positive for A2059G mutations additionally had a Moxifloxacin resistance. Resistance guided therapy is crucial for sufficient treatment success and addition of molecular resistance testing against Fluoroquinolones is an additional requirement.

Presenter email address: obermeier@mvz-mib.de
Abstract 4963

**Value of pneumococcal urinary antigen testing in a recent series of Streptococcus pneumoniae bacteraemia**

Andrea García Caballero1, María Isabel Serrano Tomás1, Daniel Marcos Mencía1, Jesus Fortun Abete1, María Isabel Moya1, Rafael Canton Moreno1, Ana María Sanchez Díaz2

1Hospital Ramón y Cajal, Madrid, Spain

**Background:** Streptococcus pneumoniae is the most frequently detected pathogen in community-acquired pneumonia and has high morbidity/mortality rates worldwide. As concomitant bacteremia worsens the prognosis, it is important to achieve an early identification of the pneumococcal diseases, to start appropriate antibiotic treatment. Pneumococcal urinary antigen testing (PUAT) is widely used, but still remains controversial due to its variable sensitivity in bacteremic-pneumonia episodes. The aim of this study was to describe the epidemiology of S. pneumoniae bacteraemia episodes in our hospital and evaluate the performance of PUAT.

**Materials/methods:** All S. pneumoniae bacteremic episodes detected in a tertiary hospital in Madrid over a period of 10 months (January-October 2019) were included. Demographic and clinical data were collected from patient’s clinical records and laboratory informatic system. Microbiological tests results, including performance of PUAT and sputum culture were reviewed, as well as antimicrobial susceptibility testing (AST) results [disk diffusion/Etest, EUCAST criteria] and serogroups classification of S. pneumoniae isolates.

**Results:** Forty-four episodes of S. pneumoniae bacteremia were identified (56.8% women, mean age 68±16.2 years), 31 of them (70.5%) associated with pneumonia. All episodes but two required hospitalization, [mean length 11.6 days]. Sputum culture was obtained only in 10 patients (22.7%), and showed poor profitability (in none of them S. pneumoniae was isolated). PUAT was performed in urine samples of 31 patients (70.5%) and showed low sensitivity (20 positive results, 64.5%). This value was even lower in patients with pneumonia (16/26 positive cases, 61.5%) than in those with other forms of pneumococcal disease (4/5 positive cases, 80%). Serogroup classification was available in 34 isolates (77.3%), being the most frequent serogroups 8 (29.4%), 3 (11.8%), 35 (11.8%) and 19 (8.8%). Regarding AST, susceptibility rates were: penicillin, 79.4%; erythromycin, 79.4%; cefotaxime, levofloxacin and vancomycin, 100%. Three isolates belonging to serogroup 19 showed resistance to erythromycin and susceptible, increased exposure to penicillin and cefotaxime.

**Conclusions:** Negative PUAT does not rule out S. pneumoniae bacteremia, even in patients diagnosed with pneumonia. The systematic implementation of the 23-valent vaccine could avoid a great number of cases, since 73.5% of the serogroups detected in this series are included in this vaccine.

**Presenter email address:** andreagarciacaballero@gmail.com
The external validity of an investigator-initiated randomised controlled trial comparing 7 versus 14 days for Gram-negative bacteraemia

Fidi Koppel*1, Eyal Baum1, Ebtehal Khazem1, Rima Nassar1, Adi Turjeman2,3, Dafna Yahav2,4, Leonard Leibovici1,2, Ami Neuberger1,5, Mical Paul1,5

1Rambam Health Care Campus, Infectious Diseases Institute, Haifa, Israel, 2Rabin Medical Center, Beilinson Hospital, Department of Medicine E, Petah Tikva, Israel, 3Tel Aviv University, Sackler Faculty of Medicine, Ramat Aviv, Tel Aviv, Israel, 4Rabin Medical Center, Beilinson Hospital, Infectious Diseases Unit, Petah Tikva, Israel, 5The Ruth and Bruce Rappaport Faculty of Medicine, Technion–Israel Institute of Technology, Haifa, Israel

**Background:** External validity determines the extent to which randomized controlled trials’ (RCT) results apply to all patients in clinical practice. We aimed to compare patients included in an investigator-initiated RCT to those with the targeted infection that were not included.

**Materials/methods:** This was a pragmatic RCT showing non-inferiority of 7 vs. 14 covering antibiotic days for Gram-negative bacteraemia, with exclusion criteria deemed necessary for patient’s safety and good clinical practice. Patients were not included mainly for uncontrolled infection at day 7, inability to provide informed consent, refusal to participate or participation in another trial. The current analysis includes patients recruited at Rambam Health Care Campus (RHCC). We compared all included patients vs. patients with Gram-negative bacteraemia that did not participate. Non-participants were selected randomly from all those with Gram-negative bacteraemia that did not participate. In a subgroup analysis, we compared the RCT cohort to patients fulfilling all inclusion criteria that refused to participate in the trial.

**Results:** 251 patients included in the RCT at RHCC were compared to 292 patients with Gram-negative bacteraemia that were not included, of whom 90 were excluded due to refusal to participate. Overall, there were large differences between participants and non-participants, with non-participants being more frequently male, and having poorer functional status at baseline, more comorbidities, nosocomial infections, urinary catheters, medical devices, higher sepsis severity caused mainly by altered mental status, higher total SOFA score and more frequent need for hemodynamic support. Outcomes were correspondingly worse among non-participants, including short and long-term mortality. Participants approached for inclusion, but refusing participation were more likely to have nosocomial infections, poorer baseline functional capacity and higher McCabe than included patients, but similar sepsis severity. In this subgroup analysis, there was no difference in mortality, but the patients who refused, experienced longer in-hospital stay and more relapses.

**Conclusions:** Patients participating in the RCT were selected for clinical stability and were different from other patients with Gram-negative bacteraemia; thus the trial results apply to selected patients fulfilling the trial’s eligibility criteria. Patients with nosocomial infections and poorer functional status were less likely to agree to participate in the RCT.

**Presenter email address:** f.koppel@rambam.health.gov.il
Unyvero multiplex PCR on broncho-alveolar lavage for rapid microbiologic and antibiotic susceptibility documentations in immunocompromised patients under antibiotic therapy admitted to the intensive care unit

Jacques Tankovic1*, Jean-Luc Baudel1, Redouane Dahoumane1, Salah Gallah1, Laurent Benzerara1, Nicolas Veziris1, Eric Maury1, Bertrand Guidet1

1Hospital Saint-Antoine AP-Hp, Université Pierre et Marie Curie, Paris, France

Background: In a specific population, immunocompromised patients admitted to our medical ICU with a diagnosis of severe pneumonia (according to clinical and radiological findings) and already treated with antibiotics, we compared the rapid (4.5 hours) microbiological documentation obtained by Unyvero multiplex PCR assay (Curetis) to those obtained by direct examination and quantitative culture. This was an observational study.

Materials/methods: We examined BAL samples performed on admission from 52 patients from July 2018 to November 2019: m/f ratio 2.1:7, age 61.9 +/- 11.7, SAPS2 score 51.5 +/- 6.8. They originated mostly from the haematology (76%) and oncology (13%) units. Informed consent was obtained from all. Because the patients were under antibiotics at admission, the threshold of clinical significance for quantitative cultures was lowered to 10^3 CFU/ml. For PCR, a positive result was considered significant whatever the qualitative score (1, 2 or 3).

Results: More than 50% of the cases (29/52, 56%) remained undocumented by culture and PCR. For the 23 cases documented by culture and/or PCR, 19 were monomicrobial, 3 bimicrobial and 1 trimicrobial. Gram stain was helpful in less than half of these documented cases (11/23). Complete documentation was obtained by culture in 19 cases; in 22 cases if a second look was performed on culture plates; by PCR in 21 cases (partial documentation, 22 cases). There were 2 major discrepancies: 1 S. aureus strain not detected by PCR; 1 S. aureus strain not detected by culture. Concerning the correlation between antibiograms and resistance genotypes, 3 discrepancies were observed: 2 penicillinase-positive enterobacteria being found TEM-negative by PCR and 1 ESBL-positive Klebsiella variicola being found ESBL-negative by PCR.

Conclusions: In this specific population, results obtained by the Unyvero assay and by culture were highly correlated. The Unyvero assay on BAL samples is useful in this specific population for rapid obtention of microbiological results and also to confirm that the negativity of cultures is not due to preexisting antibiotic treatment. It thus permits a better management of antibiotic therapy, leading to a reduction of antibiotic resistance selection pressure in the ICU.

Abstract 4967

**Communication of rapid identification results from positive blood cultures decreases time to effective therapy**

Reem Haj1, Linda Taggart1, Jessica Forbes2, Elizabeth Leung1, Jenny Wu3, Ramzi Fattouh1, Larissa Matukas*1

1University of Toronto - St. George Campus, St. Michael’s Hospital, Toronto, Canada, 2University of Toronto - St. George Campus, Toronto, Canada, 3St. Michael’s Hospital, Toronto, Canada

**Background:** Implementation of rapid bacterial identification systems, in conjunction with antimicrobial stewardship programs (ASP), has repeatedly demonstrated improvement in time to appropriate therapy, decreased mortality, length of hospital stay and cost in patients with bacteremia. Whilst these previous studies notified ASP, in this study we examined the impact of rapid MALDI-ToF identification from positive blood cultures (BC) with verbal communication of the results to the intensive care unit (ICU) instead of ASP.

**Materials/methods:** During the study period between April 2018 to December 2019, time to therapy was compared in the pre-intervention and post intervention periods for bacteremic patients admitted to the ICU. In the pre-intervention period, BCs were processed as per standard procedures, with Gram stain communication to the ICU on the day of BC positivity; MALDI-ToF identification was performed on subcultures the following day with no additional communication of results. In the post-intervention period a rapid identification from BC was performed on the day of BC positivity and the result was communicated to the ICU within 2 hours of Gram stain notification. Descriptive analytics of antimicrobial use, spectrum and patient outcomes was performed.

**Results:**

**Conclusions:** This pilot study demonstrates that communication of rapid identification results from positive BCs can reduce time to effective therapy in ICU patients with bacteremias. Further studies are needed to determine if this is broadly applicable to other organisms, thereby reducing the burden on ASP personnel whilst achieving the goal of patients receiving optimal antimicrobial therapy as quickly as possible.

The challenge of managing bone and joint infection in the OVIVA era: significant drug/drug interactions are much more common in patients managed with oral regimes

Ritchie Neil*1, Amy Brown1, Fiona Robb1, Lee Stewart1, Pauline Wright1

1Queen Elizabeth University Hospital, Glasgow, United Kingdom

**Background:** The recently published Oral Versus Intra-Venous Antibiotics (OVIVA) study demonstrated the non-inferiority of oral antibiotic regimes to intravenous equivalents in bone and joint infection (BJI). However, oral regimes may be more challenging to use with drug-drug interactions (DDI) frequently encountered.

**Materials/methods:** The medication record of consecutive patients with BJI discussed at our institution’s BJI MDT during 2018 were reviewed. DDI involving oral and intravenous antibiotics commonly used by our OPAT service were assessed using the British National Formulary (BNF). QT prolonging drugs were assessed using crediblemeds.org. DDI classed as “moderate” or “severe” were considered significant. Topical/inhaled medications were excluded.

**Results:** 178 patients were included [53% male, mean age 64]. Patients were prescribed a total of 168 different medications (median 6 [range 0-19] medications per patient). Each patient’s drug history was assessed for DDI with the commonly used antibiotics, the mean number of DDI/patient is shown in the table. 148/178 (86%) of patients had at least one potential DDI to the commonly used oral antibiotics whereas only 86/178 (48%) had at least one DDI with common parenteral drugs, usually daptomycin. DDI were found affecting drugs used to treat a wide range of conditions, but 77/1381 (64%) DDI concerned drugs found in 5 BNF subsections: Hyperlipidaemia, Pain, Depression, Pain and Inflammation in musculoskeletal conditions, and Hypertension.

**Oral antibiotics**

| Doxycycline                     | 0.28 [2]                     | 26%                             |
| Ciprofloxacin                   | 1.15 [9]                     | 54%                             |
| Levofloxacin                    | 0.90 [9]                     | 42%                             |
| Rifampicin                      | 1.71 [9]                     | 78%                             |
| Linezolid                       | 0.43 [3]                     | 37%                             |
| Co-trimoxazole                  | 0.06 [2]                     | 5%                              |
| Fusidic acid                    | 0.34 [1]                     | 34%                             |
| Clindamycin                     | 0 [n/a]                      | 0%                              |

**Conclusions:** In general, oral antibiotics used within our service for the management of bone and joint infection are associated with significantly higher rates of DDI compared to parenteral antibiotics. Many patients have multiple potential DDIs and individualisation of care with changes in anti-microbial therapy or regularly prescribed medications may be required to maximise treatment effectiveness and avoid potentially serious adverse effects.

Abstract 4969

Treatment responses to azithromycin and ciprofloxacin in uncomplicated Salmonella Typhi infection: a comparison of clinical and microbiological data from a controlled human infection model

Malick Gibani*1,2, Celina Jin1, Shaun Pennington1, Xinxue Liu1, Alison Ardrey2, Ghaith Aljayyoussi1, Maria Moore1, Brian Angus1, Chris Parry1, Giancarlo Biagini3, Nicholas Feasey1, Andrew Pollard1

1Oxford Vaccine Group, Department of Paediatrics, University of Oxford, Oxford, United Kingdom, 2Imperial College London, Department of Infectious Diseases, London, United Kingdom, 3Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 4John Radcliffe Hospital, Nuffield Department of Medicine, Headington, United Kingdom

Background: The treatment of enteric fever is complicated by the emergence of antimicrobial resistant Salmonella Typhi. Azithromycin is commonly used for first-line treatment of uncomplicated enteric fever, but the response to treatment may be sub-optimal in some patient groups when compared with fluoroquinolones.

Materials/methods: We performed an analysis of treatment responses with azithromycin (500mg once-daily, 14 days) or ciprofloxacin (500mg twice-daily, 14 days) in healthy UK volunteers (18-60 years) enrolled into two Salmonella human challenge studies. Study A was a single-centre, open-label, randomised trial. Participants were randomised 1:1 to receive open-label oral ciprofloxacin or azithromycin, stratified by vaccine group (Vi-polysaccharide, Vi-conjugate or control Men-ACWY vaccine). Study B was an observational challenge/re-challenge study of Salmonella Typhi infection. Outcome measures included fever-clearance-time, blood-culture clearance time and plasma drug concentrations.

Results: In 81 participants diagnosed with S. Typhi, treatment with azithromycin was associated with prolonged bacteraemia (median 90.8 hours [95% CI:65.9-93.8] vs. 20.1 hours [95% CI:78-24.3], p<0.001) and prolonged fever clearance times <37.5°C [hazard ratio 2.4 [95%CI:1.25-5.0]; p=0.02]. Results were consistent when studies were analysed independently and in a sub-group of participants with no history of vaccination or previous challenge. A prolonged treatment response was observed significantly more frequently in the azithromycin group [28/52 [54.9%]] compared with the ciprofloxacin group [1/29 [3.5%]; p<0.001]. In participants treated with azithromycin, plasma concentrations of azithromycin did not exceed the MIC, whilst predicted intracellular concentrations did exceed the MIC. In participants treated with ciprofloxacin, the measured plasma concentrations and predicted intracellular concentrations of ciprofloxacin exceeded the MIC.

Conclusions: Azithromycin at a dose of 500mg daily is an effective treatment for fully sensitive strains of S. Typhi but is associated with delayed treatment response and prolonged bacteraemia when compared with ciprofloxacin within the context of a human challenge model. Whilst the cellular accumulation of azithromycin is predicted to be sufficient to treat intracellular S. Typhi, systemic exposure may be sub-optimal for the elimination of extracellular circulating S. Typhi. In an era of increasing antimicrobial resistance, further studies are required to define appropriate azithromycin dosing regimens for enteric fever and to assess novel treatment strategies, including combination therapies.

"Seek and ye shall find": endoscopic finding and molecular diagnosis of Trichuris trichiura

Marco Peradotto*1, Zaccaria Teresa1, Cavallero Serena2, Alessandro Bondi1, Bottino Paolo1, Cristina Costa1, Stefano D’amelio2, Rossana Cavallo1

1Microbiology and Virology U, Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy
2Department of Public Health and Infectious Diseases, La Sapienza University of Rome, Rome, Italy

Background: Whipworms are responsible of approximately 500 million cases of trichuriasis worldwide, with higher endemity in tropical and sub-tropical countries. At first, the infection is asymptomatic, but it can develop with variable symptoms according to parasite load. Diagnosis in mainly based on the detection of eggs at microscopy, but this technique lacks sensitivity. In non-endemic countries trichuriasis can be accidentally diagnosed by colonoscopy, often in presence of negative microscopy. Here, we describe an incidental diagnosis in non-endemic country (Turin, North-West Italy).

Materials/methods: A 52 years old HIV-positive Italian man, presenting family history for colorectal cancer, was referred for colonoscopy reporting one week diarrhoea and mild abdominal pain, without fever and bleeding, which resolved leaving no discomfort. No blood chemistry or faecal parasites examination had been done before. At first, the patient only declared raw fish consumption, suggestive for fish-borne parasites. Endoscopy showed the presence of a whitish motile nematode-like organism in the caecal region. Only a portion of the organism (7×0.5mm) could be removed.

Results: Apparently, macroscopic aspect and microscopy agreed with the caudal portion of an Anisakidae. The presence of ova overflowing from the ruptured end was the only clash. Thus, the nematode was sent to Italian Reference Centre for Anisakiasis (Palermo) for RFLP and to Parasitology Section at La Sapienza University in Rome for molecular analysis of mitochondrial cytochrome b gene.

The pattern obtained with RFLP was dissimilar from Anisakis spp and cytochrome b sequencing showed high percentage of identity with Trichuris trichiura. In a second medical interview the patient reported a travel to Antigua six months before the colonoscopy. Although asymptomatic, the patient was treated after nematode removal (two administrations 400 mg oral albendazole at time 0 and after 30 days).

Conclusions: Considering the high prevalence of Trichuris in Antigua [up to 30% in children], we may consider this case a travel-related imported infection. Endoscopy is the most diffused [often accidental] diagnostic tool for identification of trichuriasis, whereas economic conditions allow the use of this technique. This case highlights how improving parasitic diseases diagnosis is a primary goal to pursue, both laboratory diagnostic tools and microbiologists training.

Abstract third-party references: German Research Foundation: Collaborative Research Centre 1027

Background: Catheter-related bloodstream infections (CRBSI) are a prominent cause of sepsis and are associated with high morbidity and mortality. CRBSI are usually triggered by the formation of biofilms on peripheral or central venous catheters (CVC), rendering the pathogen less susceptible to anti-infective therapy. Attachment of the pathogen to the catheter surface is a basic condition of biofilm formation, thus a pathogens ability to adhere to such a surface can be considered a fundamental virulence feature. Besides Staphylococci, the yeast *Candida albicans* is a major source of CRBSI. *C. albicans* can form two major morphotypes, the yeast stage thought to contribute primarily to distribution and dissemination, and the hyphae stage, which is believed to promote cell invasion and biofilm maturation. However, the role of these morphotypes in initial adhesion is still debated. The presence of blood serum and a temperature of 37 °C are strong triggers of a yeast to hyphae transition inducing the rapid outgrowth of initial hyphae within minutes.

Materials/methods: We utilized Single Cell Force Spectroscopy (SCFS) and flow chamber experiments to investigate the contribution of *C. albicans* yeast and hyphae cells to the adhesion to commonly used CVC.

Results: Our SCFS results showed that *C. albicans* cells in the early hyphae stage, induced by incubation of yeast cells in human blood serum, attach with a significantly higher adhesion force to serum-coated/uncoated CVCs than yeast cells. Channeling early-stage hyphae through a flow chamber, using serum-coated CVC material as a substrate for adhesion, revealed a flow directional adhesion pattern, with apical hyphae tips orientating in opposite flow direction.

Conclusions: Our results indicate that the contribution of *C. albicans* hyphae to initial adhesion is bigger than currently expected. We suggest an anchoring function of early stage hyphae tips, facilitating the adherence to CVC in the blood stream. We hope that our results will contribute to the development of medical devices less susceptible to the adherence of *C. albicans* and other biofilm-forming pathogens.

Abstract 4973

Retrospective WGS of Acinetobacter baumannii over 6.5-year-period reveals former unknown structure of clusters and uncovers resistance profile

Andrea Groß*1, Julia Rauch1, Winfried Ebner1, Hajo Grundmann1, Sandra Reuter1

1University Medical Center Freiburg, Infection Prevention and Hospital Epidemiology, Freiburg, Germany

Background: Multi-drug resistant Acinetobacter baumannii (MDR Ab) are known to be responsible for nosocomial outbreaks, caused by a limited number of clones that spread worldwide. Locally, we observed several clusters as identified by AFLP of MDR Ab in colonized or infected patients from February 2012 to September 2018. We could not exclude long-term circulation of particular clones to be responsible, and thus employed sequencing for higher resolution to investigate the local population structure and to analyze their resistance profile.

Materials/methods: 76 patients with MDR Ab were identified and 82 isolates collected. Sequencing was performed using an Illumina MiSeq.

Results: Most strains sequenced belonged to global clone 2 (GC2) \(n=57, 70\%\), 7 to GC1 \(9\%\), the others belonged to sequence types \(ST\) not related to these global clones \(n=13, 16\%\) as well as non-Ab but Acinetobacter calcoaceticus-Acinetobacter baumannii complex isolates \(n=4\) and 1 unclassified Acinetobacter strain.

In the GC2 group we found nine clusters. Three of these clusters were in agreement with AFLP. Sequence analysis here added higher resolution as to which strains had to be included or excluded in addition to the ones originally identified. In the GC2 group, some clusters showed clear discrimination to the other clusters \(> 105\) SNPs); however one clade contained several transmission chains, each of which had an intermediate number of SNPs \(20-50\) to the others.

In the non-GC2 group we found two clusters in agreement with the AFLP assignment indicative of recent transmission events. No direct transmission events were detected in GC1.

Genes detected for antibiotic resistances were in concordance with phenotypic resistance patterns, and were conserved within transmission chains.

Conclusions: Sequencing confirmed most previously assigned clusters but more precisely elucidated the structure of phylogeny and the position of strains that were considered to be unrelated. Additionally WGS supported the investigation of possible transmission links. We found no evidence for our suspicion of a single clone spawning a long-term transmission chain but our data show, that improvement of surveillance strategies would be needed to eliminate the risks of epidemic as well as endemic MDR clones because they pose a potential risk for future outbreaks.

Epidemiology and antifungal susceptibility patterns of invasive fungal infections from 2012 to 2014 in a teaching hospital in central China

Shu-Ying Yu*, Menglan Zhou1, Yingchun Xu1

1Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: As participants of the national China Hospital Invasive Fungal Surveillance Net (CHIF-NET) program, we sought to describe the epidemiology and antifungal susceptibility patterns of yeast isolates obtained from patients with invasive fungal infection at the First Affiliated Hospital of Zhengzhou University, China.

Materials/methods: A total of 434 yeast isolates recovered from blood and other sterile body fluids were identified to species by matrix-assisted laser desorption ionization–time of flight mass spectrometry with or without supplementation by DNA sequencing. Antifungal susceptibilities were determined by Sensititre YeastOneTM YO10 methodology.

Results: Candida albicans was the most common causative species (33.9% of isolates) but significantly decreased in frequency from 37.2% to 27.7% from 2012 to 2014. C. tropicalis was the next most common pathogen (25.1%), followed by C. parapsilosis complex (17.3%), C. glabrata (9%) and C. pelliculosa (6.7%), with other species comprising 8% of isolates. Caspofungin, micafungin and anidulafungin exhibited potent in vitro activities against the majority of Candida isolates. Azoles demonstrated in vitro activities against C. albicans with a susceptibility rate of >95% and against C. parapsilosis complex, >95% isolates were susceptible. Amongst C. tropicalis and C. glabrata isolates, resistance rates to fluconazole and voriconazole were 11.9%, 9.1% and 7.7%, 28.2%, respectively. Of note, C. pelliculosa had a high incidence rate in newborns and high rates of resistance to fluconazole and voriconazole of 55.2% and 41.4%, respectively.

Conclusions: The present study provided valuable local surveillance data on the epidemiology and antifungal susceptibilities of invasive yeast species, which is essential for guiding antifungal treatment protocol development.

Abstract 4978

The EUCAST Rapid AST directly from positive blood culture bottles: breakpoints for additional antimicrobial agents for Escherichia coli, Klebsiella pneumoniae and Pseudomonas aeruginosa

Emma Jonasson1, Erika Matuschek2, Gunnar Kahlmeter2,3

1Central Hospital, Växjö, Department of Clinical microbiology, Växjö, Sweden, 2EUCAST Development laboratory, EUCAST Development laboratory, Växjö, Sweden, 3Central Hospital, Växjö, Department of Clinical microbiology, Växjö, Sweden

Background: The EUCAST method for rapid antimicrobial susceptibility testing (RAST) is available on the EUCAST website since November 2018. The initial limited range of antimicrobial agents for Escherichia coli, Klebsiella pneumoniae and Pseudomonas aeruginosa needs to be extended. The objective of this study was to determine breakpoints for additional agents important in the treatment of sepsis.

Materials/methods: BC bottles, BACTEC® Plus Aerobic (BD), were inoculated with isolates of E. coli (n=65), K. pneumoniae (n=53) and P. aeruginosa (n=60) together with 5 mL defibrinated horse blood and placed in the BACTEC FX system (BD). Isolates susceptible and resistant isolates for each antimicrobial agent were included (Table). Disk diffusion was performed according to the EUCAST RAST methodology using Mueller-Hinton agar from two manufacturers (BBL/BD and Oxoid/Thermo Fisher Scientific). Inhibitions zones were read after 4, 6 and 8h incubation (6 and 8h for P. aeruginosa), on the same re-incubated plates. MIC values from broth microdilution according to ISO 20776-1 interpreted according to EUCAST breakpoints v.9.0 (2019), were used as reference. Proposed breakpoints were set to correctly categorise as many isolates as possible and to avoid false susceptible results.

Results: We were able to determine RAST breakpoints for the additional agents. The proportion of readable zones corresponded to results for other, previously investigated, agents. As previously, an Area of Technical Uncertainty (ATU) was introduced to reduce categorical errors. Less than 16% of all readable zones were categorised as ATU. RAST for ceftolozane-tazobactam was difficult for both E. coli and K. pneumoniae. With the suggested breakpoints more than 95%, 94% and 96% of all isolates were correctly categorised as susceptible or resistant for E. coli, K. pneumoniae and P. aeruginosa respectively. With the suggested breakpoints there were only two false susceptible results.

Conclusions: This study shows that the EUCAST RAST method can now be used for several additional clinically relevant antimicrobial agents for E. coli, K. pneumoniae and P. aeruginosa. As with other agents, the number of errors is low, especially false susceptible results, when testing a collection of isolates with high number of resistant isolates with varying MIC values.

Table. Theoretical and actual number of tests, the proportion of tests which could be read and interpreted after 4, 6 and 8 h, and the categorical errors with RAST at each reading time for E. coli, K. pneumoniae and P. aeruginosa.

For each table, data are presented as (letters relating to footnotes):
A. The theoretical number of tests = Total number of possible isolate-agent combinations in duplicate (since data on media from two manufacturers).
B. Number of completed tests = Number of completed test after excluding missing data (e.g. disk dropped).
C. Readable zones = Number of tests with readable inhibition zones.

Abstract 4980

Location and numbers of handrub dispensers in Swiss hospitals: a representative survey to establish a national minimal standard

Sabine Kuster*1, Jan A. Roth1, Marc Dangel1, Didier Pittet2,3, Andreas F. Widmer1,3

1University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 2University of Geneva Hospitals and Faculty of Medicine, Infection Control Program and World Health Organization (WHO) Collaborative Center, Geneva, Switzerland, 3Swissnoso, Nationales Zentrum für Infektprävention, Bern, Switzerland

Background: Hand hygiene (HH) using alcohol-based handrub (ABHR) belongs to the standards of care for infection control to prevent transmission of pathogens. Data on numbers and best location for ABHR dispensers (ABHR-D) are scarce. The German Office of Public Health (RKI) recommends at least one dispenser per bed in intensive care units and 0.5 dispenser per bed in general wards. WHO, CDC and ECDC do not provide exact recommendations on the number of ABHR-Ds. We investigated the actual numbers and location of ABHR-Ds in Switzerland.

Materials/methods: Between 7/19-9/19, we asked all 178 hospitals participating in the Swissnoso National surveillance Network, representing around 80% of Swiss acute care hospitals, to respond to an anonymous, standardized questionnaire on HH practices with emphasis on numbers of ABHR-Ds per bed and location. The questionnaire was addressed to board-certified infection control practitioners and hospital epidemiologists. Non-responders were reminded twice before being considered as non-compliant.

Results: 110 of 178 (61.8%) participating hospitals provided data, representing approximately 20’000 hospital beds. 66 hospitals (60%) have more than 100 beds. Pocket-sized dispensers (100ml) are used in 97.3% (n=107) of hospitals, but in only 28.2% (n=31) pocket dispensers are the preferred way of distribution. The reported median number was 2 ABHR-D per room (mean: 1.83, range 1-4). 91 out of 110 hospitals (82.7%) provided detailed data on the total amount of beds and dispensers within the building, reporting a median of 2.38 (range 0.38-22.1). A majority of hospitals (83.6%, n=92) had dispensers located at the entrance of the room; 73.6% (n=81) have a ABHR-D near the sink, 28.2% (n=31) within one-meter radius of the bed and 23.6% had a dispenser at the bottom of the bed. In total, 47.3% (n=52) hospitals reported a ABHR-D location near or at the bed. Other frequently mentioned locations were mobile devices such as computer trolleys.

Conclusions: Swiss hospitals have on average 2.38 dispensers per bed four times as many as recommended by RKI. This is the very first study evaluating the number of ABHR-Ds in hospitals and may serve as new minimal standard for HH lacking standards issued by WHO, CDC and ECDC.

Ceftazidime-avibactam resistance and restoration of carbapenem susceptibility in KPC-producing Klebsiella pneumoniae infections

Suzanne Aura Victoria Van Asten*, Matteo Boattini1, Gabriele Bianco, Margriet Kraakman2, Cristina Costa1, Rossana Cavallo2, Alexandra T. Bernards1

1University of Turin, Torino, Italy, 2Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Since the introduction of the ß-lactam/ß-lactamase inhibitor ceftazidime-avibactam (C-A), rapid evolution of resistance has been reported in different KPC-producing Klebsiella pneumoniae isolates. In this multicenter retrospective study we describe the emergence of C-A resistance and evaluate the mutations that might be responsible for the restoration of carbapenem susceptibility.

Materials/methods: During a study period of 18 months, KPC-producing K. pneumoniae isolates of five hospitalized patients were collected with phenotypic development of C-A resistance.

Results: In vitro restoration of carbapenem susceptibility during treatment was observed in 3 isolates. Whole genome sequencing of these isolates showed a D179Y mutation in the KPC gene of 2 variants and a KPC-2 with a Δ242-GT-243 deletion (KPC-14). Two KPC-3 variants showed C-A resistance with sustained carbapenemase activity without genomic adaptations in the KPC gene.

Conclusions: This study confirms the emergence of C-A resistance in KPC K. pneumoniae. The role of carbapenems in treating patients with these variants is unclear and combination therapies warrant further investigation.

Table 1. Phenotypic and molecular characterization of KPC-producing Klebsiella pneumoniae isolates before (A) and following (B) ceftazidime-avibactam treatment

**Vaccinium macrocarpon urine metabolites inhibit Candida albicans adhesion and biofilm formation**
Emerenziana Ottaviano*, Giovanna Baron, Laura Fumagalli, Pietro Allegrini, Antonella Riva, Giulia Morace, Giancarlo Aldini, Elisa Borghi

1Università degli Studi di Milano, Department of Health Sciences, Milan, Italy, 2Università degli Studi di Milano, Department of Pharmaceutical Sciences, Milan, Italy, 3Indena SpA, Milan, Italy.

**Background:** Candida albicans urinary tract infections (UTI) are increasingly common in hospital settings due to its high propensity to form biofilms on mucosal surface and plastic surface of indwelling devices. Vaccinium macrocarpon (cranberry) has been widely used for decades in the prevention of UTIs in the general population. Proanthocyanidins (PACs), in particular the A-type, are the main responsible for the in vitro activity. Nevertheless, there are controversial results on their presence in human urine after cranberry oral intake. The aim of the work was i) to identify and quantify cranberry components and metabolites in human urine after the oral intake of a highly-standardized cranberry extract (Anthocran™, Indena S.p.A.), ii) to evaluate the urine ex vivo effect on C. albicans adhesion and biofilm formation and iii) to test the in vitro activity of a mixture of metabolites identified in the active fractions.

**Materials/methods:** Ten young healthy female volunteers took 2 capsules Anthocran™/day for 7 days. Urine samples were collected before starting supplementation and at the following time-points after the last dose: 1, 2, 4, 6, 10, 12, 24 hours. An HPLC-MS/MS method was set-up using a LTQ-XL-Orbitrap working in data dependent scan mode to perform the analyses. A targeted and an untargeted approach was used to identify known metabolites and compounds hereto unreported in the literature. Urine fractions were tested in vitro against the reference strain C. albicans SC5314 and eight clinical isolates from UTIs.

**Results:** Urine fractions collected after 1 and 12 hours were found to significantly reduce the adhesion. The ex vivo effect of cranberry metabolites was then confirmed by evaluating the significant inhibitory effect of a reconstituted mixture of metabolites on C. albicans adhesion and biofilm formation.

**Conclusions:** The data reported in the present work demonstrate that i) PACs are metabolized after cranberry oral intake, ii) urines collected following one week of cranberry treatment are able to significantly reduce C. albicans adhesion and biofilm formation, iii) the activity can be due to a synergistic effect of identified cranberry metabolites including PACs metabolites.

Abstract 4985

Direct-from-Blood-Culture NG-Test CTX-M Multi and Carba 5 assay to predict extended-spectrum β-lactam resistance of Escherichia coli and Klebsiella pneumoniae

Liliana Giordano1, Tiziana D’inzeo1,2, Barbara Fiori1,2,3, Venere Cortazzo1, Giulia Menchinelli1, Flora Marzia Liotti1, Maria Federica Ventriglia1, Giulia De Angelis1, Brunella Posteraro1,5, Maurizio Sanguinetti1,2, Teresa Spanu1,2

1Institute of Microbiology, Università Cattolica del Sacro Cuore, Rome, Italy, 2Dipartimento di Scienze di Laboratorio e Infettivo-logiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, 3Scuola Provinciale Superiore di Sanità Claudiana, Bolzano, Italy, 4Institute of Medical Pathology and Semeiotics, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy, 5Dipartimento di Scienze Gastroenterologiche, Endocrino-Metaboliche e Nefro-Urológiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: Bloodstream infections (BSIs) caused by extended-spectrum β-lactamases and carbapenemase-producing Escherichia coli and Klebsiella pneumoniae are associated with treatment failure and increased mortality. Rapid, reliable detection of these organisms may help clinicians to provide more adequate therapy during the early period of clinical illness. We aimed to determine the feasibility of using the rapid NG-test CTX-M MULTI and the NG-Test Carba 5 immunochromatographic (ICT) assays directly from positive blood cultures (BCs) to predict phenotypic resistance to cefotaxime, ceftazidime, imipenem and meropenem.

Materials/methods: Analysis was prospectively carried out on 630 consecutively positive BCs from nonduplicate patients, in which the presence of K. pneumoniae or E. coli was detected by direct MALDI-TOF mass spectrometry analysis from positive BC broths. All BC samples were then tested with the NG-test CTX-M MULTI and the NG-Test Carba 5 according to the manufacturer’s instructions with some modifications. Test results were read by eye after 15 minutes of migration at room temperature. ICT results were compared to phenotypic resistance as determined by broth microdilution method which was performed and interpreted according to EUCAST clinical breakpoints. Carbapenemase, extended-spectrum and plasmid-mediated AmpC β-lactamase genes were further identified by PCR assay and sequencing.

Results: Overall 41.3% of the isolates were resistant to cefotaxime, 36.3% to ceftazidime, 8.6% to imipenem and 9.0% to meropenem. The sensitivity of the NG-test CTX-M MULTI and the NG-Test Carba 5 to predict ceftriaxone and ceftazidime resistance was 0.95 (95% confidence interval [CI] 0.92–0.97) and 0.95 (95%CI 0.91-0.97), respectively, while the specificity was 1 (95%CI 0.99-1) and 0.92 (95%CI 0.89-0.95), respectively. The sensitivity of the NG-Test Carba 5 to predict imipenem and meropenem resistance was 0.98 (95%CI 0.90-0.99) and 0.97 (95%CI 0.88-0.99), respectively, while the specificity was 0.99% (95%CI 0.97-0.99) and 0.98 (95%CI 0.97-0.99), respectively.

Conclusions: Although further studies are needed to assess their performance in routine diagnostics, our experience with this large series of E. coli- and K. pneumoniae-positive BCs indicates that the NG-test CTX-M MULTI and the NG-Test Carba 5 assays accurately predict resistance to β-lactam antimicrobials used in the treatment of BSIs caused by E. coli and K. pneumoniae isolates.

Abstract 4988

Limited genetic diversity of blaCMY-2-containing IncI1-ST12 plasmids from Enterobacteriaceae of diverse human and broiler origin in the Netherlands

Evert Den Drijver*, Joep Stohr1,2, Jaco Verweij1, Carlo Verhulst1, Franciscia Velkers1, Arjan Stegeman1, Marjolein Kluytmans - Van Den Bergh1,5, Jan A. J. W. Kluytmans2,5

1Elisabeth-TweeSteden Hospital, Tilburg, Netherlands, 2Amphia Hospital, Breda, Netherlands, 4Universiteit Utrecht Faculty of Veterinary Medicine, Utrecht, Netherlands, 4Amphia Hospital, Academy Infectious Disease Foundation, Breda, Netherlands, 5Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands

**Background:** IncI1 plasmid sequence type [pST] 12 has been linked to the spread of blaCMY-2, the most common plasmid-encoded ampC gene. So far, literature is scarce on the genetic diversity of IncI1-pST12 plasmid sequences. Next-generation sequencing (NGS)-based analysis of blaCMY-2 IncI1-pST12 plasmids in Enterobacteriaceae from Dutch hospitalised patients and broilers was performed to investigate their genetic diversity.

**Materials/methods:** Short-read sequence data (Illumina, Dan Diego, US) in our local NGS database of Enterobacteriaceae cultured from humans and broilers were screened for the presence of both a blaCMY-2 gene and an IncI1-pST12 replicon. Six E. coli and one Salmonella enterica from different sequence type [ST] and origin (human or broiler) were selected the present analysis [Figure]. De novo assembly was performed with SPAdes v3.12, followed by in silico plasmid extraction using an IncI1-pST12 reference plasmid. The plasmid constructs and the IncI1-pST12 reference plasmid were aligned using progressiveMAUVE v2.4.0, creating a genome-content distance matrix reflecting the mean proportion of shared genomic content. Pairwise single nucleotide polymorphisms [SNP] were determined using Snippy v4.4.5. The plasmids were annotated using Prokka v1.13.3 and a pan-genome was constructed using Roary v3.12.

**Results:** The genome-content distance in pairwise comparisons with the reference plasmid ranged from 0.00 to 0.04. The number of SNP's detected between the plasmid constructs and the reference IncI1-pST12 plasmid ranged from 1 to 8 [Figure]. One-hundred and one genes (82%) of the pan-genome of 124 genes were present in all plasmid constructs, where the number of genes being variably present or absent between the plasmids ranged from 1 to 16 [Figure].

**Conclusions:** NGS-analysis of seven blaCMY-2-containing IncI1-pST12 plasmids isolated from epidemiologically unrelated Enterobacteriaceae shows a high degree of sequence similarity in terms of a low number of SNP differences and a high number of shared genes. Given the conserved genome of these plasmids, judgements on the horizontal transfer based on genetic identity should be made with caution.

Prevalence of Chlamydia trachomatis and Neisseria gonorrhoeae at extragenital sites in the north metropolitan area in Catalonia

Cristina Casas1, Gema Fernández Rivas1,2, Àgueda Hernández Rodríguez1,2, Maria Carrasco1, Georgina Linares1, Belen Rivaya Sanchez1,2, Nona Romani Rodés1, Anabel Fernández Navarro1, Lurdes Matas Andreu1,2

1Hospital Germans Trias i Pujol, Badalona, Spain, 2Universitat Autònoma de Barcelona, Bellaterra, Spain

Background: Chlamydia trachomatis [CT] and Neisseria gonorrhoeae [NG], not only cause urethritis and cervicitis, but also can be detected at extragenital sites (rectum, pharynx). Extragenital chlamydia and gonorrhoea infections are commonly reported in men who have sex with men (MSM). Recent studies suggest the prevalence of extragenital infections in heterosexuals, mainly in women, may be increasing. We aimed to evaluate extragenital sexually transmitted infections [STIs] prevalence in our environment.

Materials/methods: This is a prospective study conducted from January-October 2019 at the Microbiology department of Laboratory Clinic Metropolitan North in Badalona [Spain]. Samples for CT and NG detection by real-time PCR came from asymptomatic and symptomatic patients. Additionally, the rectal swabs which were positive for CT, were retested by real-time PCR for Lymphogranuloma venereum [LGV] detection.

Results: A total of 550 rectal swabs were analyzed. Of them, 14% were positive for CT and 7.6% were positive for NG. LGV was positive in MSM, 35/39 (90%). Meanwhile, in heterosexual population was positive 1/37 (3%). Besides, 1255 pharyngeal swabs were analyzed. Of them, 4% were positive for CT and 3% were positive for NG. The samples received from women were 1156/1375 (84%) and from MSM were 430. Table 1.

Conclusions: MSM and women seem to have a higher risk of extragenital STIs. The prevalence of chlamydia infection in heterosexual population, which practice anal intercourse, is as high as MSM. However, the majority MSM reported were LGV, but in heterosexual population was uncommon. Due to STIs have been increasing in genital sites in the last few years; maybe they have also been rising in rectum and pharynx. We recommend analyzing all anatomical sites according to sexual behavior.

The economic burden of carbapenem-resistant non-fermenting Gram-negative bacteria healthcare-associated infections

Yiying Cai*1,2, Clara Wong1, Winnie Lee1, Jocelyn Teo1,3, Tze-Peng Lim1,4,5, Ban Hock Tan1, Andrea Kwa1,5,6

1Singapore General Hospital, Singapore, Singapore, 2National University of Singapore, Singapore, Singapore, 3National University of Singapore and National University Health System, Saw Swee Hock School of Public Health, Singapore, Singapore, 4SingHealth Duke-NUS Pathology ACP, Singapore, Singapore, 5SingHealth Duke-NUS Medicine ACP, Singapore, Singapore, 6Duke-NUS Medical School, Singapore, Singapore

Background: CRNF HAIs are a major public health threat. Quantifying the economic burden of CRNF HAIs to hospitals can assist decision makers in determining the investments for prevention and control. We determined the cost of a single CRNF HAI from a hospital’s perspective, and estimated the annual economic impact of CRNF HAIs to a Singapore hospital.

Materials/methods: We conducted a matched case-control study for CRNF and carbapenem-susceptible non-fermenting Gram-negative bacteria (CSNF) HAI patients in a 1,700-bedded tertiary hospital in Singapore, matched for organism, time at risk and admitting ward. Probabilities and outcomes were entered into a tree diagram to estimate the cost of a CRNF HAI for the duration of the infection from the hospital’s perspective, and compared to the cost of a CSNF HAI (Figure 1). Cost of individual components (e.g. bed-day cost, hourly wages, instrumentation) were obtained from nationally representative local databases. All costs were adjusted to 2016 SGD using a 3% inflation rate. Monte Carlo simulations were performed, comprising 1000 trials, varying distributions through their ranges. The annual economic burden of CRNF HAIs was determined by extrapolating the cost data to the hospital’s annual CRNF HAI incidence. Scenario analyses were further conducted.

Results: The median cost of a single CRNF HAI from the hospital’s perspective was $33,424 (90% credibility ranges (CR), $23,314-$46,556), which is markedly higher than the median cost of a single CSNF HAI [$13,030; 90% CR, $8,149-$23,562]. Approximately 50% of the cost incurred consisted of productivity losses in healthcare workers [$8,941 (90% CR, $3,011-$21,746)] and loss in opportunity costs for lost room and board [$8,207 (90% CR, $2,729-$19,834)]. The costliest CRNF HAIs are intra-abdominal infections [$46,988 ($35,804-$59,638)] and pneumonia [$39,371 ($19,127-$80,144)]. Extrapolating this to our annual CRNF HAI incidence (incidence rate of 51.10 per 10,000 admissions), CRNF HAIs will cost the hospital approximately $15.07 million/year. A reduction in CRNF incidence rates by 20% will lead to cost savings of SGD$3.01 million/year.

Conclusions: HAIs caused by CRNF were associated with substantial costs to the hospital. Efforts should be made to prevent these nosocomial infections to allow healthcare resources to be better employed for other purposes.

Abstract third-party references: Study Sponsored by Shionogi Europe

Background: Antimicrobial resistance is a major global threat with potentially devastating consequences and significant costs to society. Carbapenems have been the main class of drugs, reserved for difficult-to-treat Gram-negative (GN) infections, but resistance is increasing worldwide; hence WHO classified carbapenem-resistant (CR) strains of Acinetobacter baumannii (CRAB), Pseudomonas aeruginosa (CRPA), and Enterobacteriaceae spp (CRE) as a critical priority. Infections by CR pathogens have few effective treatment options, with suboptimal use and scarce clinical trial evidence. In this study, we describe the diagnosis and management pathway of patients who are treated for Carbapenem non-susceptible GN (CarbNS-GN) infection.

Materials/methods: Retrospective chart review from 9 sites in UK. Eligible adult patients were randomly selected from part 1 of this study [an epidemiology survey including all patients with a GN pathogen] and included if had confirmed CarbNS-GN infection and admitted into hospital between April 2017 and March 2018. Index date was considered the first CarbNS-GN positive sample. Data collected included patient demographics, microbiology results, treatment history including pre-hospitalization, travel history, management pathway, survival and discharge status.

Results: 157 patients with CarbNS-GN infections were included, mean age was 63.3 years, 62% were male, and 17.5% patients had ≥2 Carb-NS pathogens identified. 78% of patients were from England, 15% from Scotland and 7% from Wales.

Overall, non-fermenter pathogens were identified in 72% of patients; CRPA was the most commonly identified pathogen (38%), followed by Stenotrophomonas maltophilia (27%) and Enterobacteriaceae spp (25%). At the end of this study 51% of these patients had died, of which 54% died in hospital. Mean time from index sample collection to sensitive therapy was 7.2 days, but patients had been on antibiotic treatment on average for 9.1 days before index date. Overall, mean time from first antibiotic prescribed to first active agent was 14.5 days.

Conclusions: Patients with CarbNS-GN infections were observed across the UK and represent an important population, with high mortality, significant burden, and high unmet medical need. Understanding the real-world management and outcomes of these patients, can help optimize antimicrobial stewardship and infection prevention and control programs, ultimately improving overall patients’ and NHS’s outcomes.

**Abstract 4995**

**Genomic analysis of the subclades C2/H30Rx and C1-M27 of Escherichia coli ST131 high-risk clone across Hungary**

Tóth Kinga*1,2, Akos Toth1, Laura Járvári1, Erika Ungvári1, Ivelina Damjanova1, Dora Szabo2

1National Public Health Center, Budapest, Hungary, 2Semmelweis University, Budapest, Hungary

**Background:** Recently burden of disease caused by third-generation cephalosporin-resistant (3rdCR) *Escherichia coli* increased the most in Europe. The ST131 high risk clone, especially C2/H30Rx subclade with *bla*\_CTX-M-15 and C1-M27 subclade with *bla*\_CTX-M-27, is the predominant lineage among 3rdCR *E. coli*. In 2018 44.6% (75/168) of invasive ESBL-producing *E. coli* isolates investigated at the National Public Health Center belonged to the ST131 clone, where the ratio of C2/H30Rx and C1-M27 was 1 to 0.8. The aim of our study was to perform genomic analysis on selected C2/H30Rx and C1-M27 ST131 *E. coli* invasive isolates in order to compare their genetic backgrounds.

**Materials/methods:** Seventeen C1-M27 and 16 C2/H30Rx ESBL-producing invasive *E. coli* isolates originated from entire country between 2015-2018 were selected. The antimicrobial susceptibility testing was performed by gradient MIC tests or broth microdilution and interpreted using EUCAST guidelines. The possible clonal relationships were investigated by core genome (cg)MLST (SeqSphere+ [Ridom]) using whole-genome sequencing (WGS) data of all isolates obtained from Illumina 251-bp paired-end sequencing. From WGS data acquired antimicrobial resistance and virulence genes were retrieved using ResFinder3.1, VirulenceFinder2.0 online tools and a pipeline based on 62 additional genes associated with extraintestinal infections.

**Results:** All the isolates proved resistant to ceftriaxone and ciprofloxacin, but susceptible to ceftazidim/avibactam, amikacin, tigecyclin, fosfomycin and carbapenems. C2/H30Rx isolates showed higher resistance rates than the C1-M27 ones to ceftazidim (87.5% vs 23.5%), tobramycin (81.3% vs 0%) and gentamicin (56.3% vs 0%). The virulome and resistome of the subclades showed high similarities, although differences were found (Fisher’s exact test, p<0.05): some adhesin genes (*sfaB, afa, dra*), some toxin genes (*cnf, astA, hylA*) and some antibiotic resistance genes (*bla*\_CTX-M-15, *gmrB19, aoC(6)-lb-cr, aoC(3)-lla*) significantly associated with C2/H30Rx; while *traD* serum-resistance gene, *senB* toxin gene and some antibiotic resistance genes (*bla*\_CTX-M-27, *sul2*) significantly associated with C1-M27. According to cgMLST, the isolates within a subclade were more closely related than between.

**Conclusions:** Despite of the similarity of their genetic background, there are differences which can associate with their phenotype in case of antibiotic resistance and virulence. The possible link between the clone dissemination, antibiotic resistance and virulence needs further investigations.

Prevalence of haematogenous seeding at distant sites in patients with Candida bloodstream infections

Natalia Castillo Almeida*, Pooja Gurram1, Christopher Grimont1, Maryam Mahmood1, Larry Baddour1, M. Rizwan Sohail1

1Mayo Clinic, Rochester, United States

Background: Bloodstream infection (BSI) by Candida spp. can be complicated by hematogenous seeding of distant sites and development of end organ infection (complicated Candida BSI). Our study aims to define the prevalence of complicated Candida BSI.

Materials/methods: We retrospectively reviewed medical records of all adults [age ≥18 years] with Candida BSI from November, 2011 to December, 2018. Cases with positive blood cultures via catheter alone [negative peripheral blood cultures] and polymicrobial cases were excluded. Patient demographics, clinical and microbiologic data, diagnostic imaging, and autopsy reports were reviewed.

Results: A total of 250 patients were identified and 125 patients met inclusion criteria. The median age at presentation was 62 years (IQR 50-71.5 years). The majority (53%) had a non-albicans Candida spp. BSI (46%, Candida glabrata). Five percent (6/125) had a complicated Candida BSI. The median time to blood culture positivity was 47 hours (IQR 33.5-53.5 hours) and the median time of clearance was 48 hours (IQR 42-96 hours). Seventy-four patients (59.2%) had an ophthalmological assessment, with a median time to evaluation of 5 days (IQR 3-7 days). Only two cases had ocular involvement (Table 1). Most (106/125, 85%) patients had imaging looking for a source of Candida BSI. More than half of the cases (65%) had a CT of the abdomen/pelvis, followed by a TTE and a TEE (25% and 18.4%, respectively). None of the cases had hepatosplenic candidiasis or endocarditis. Two patients had infected thrombi of the superior vena cava and transjugular intrahepatic portosystemic shunt that were confirmed by PET/CT and SPECT scan, respectively. Four cases had an infection recurrence. Three of the four cases relapsed (same Candida spp.) and one case had a re-infection (different Candida spp.). The median time of recurrence was 52.5 days (IQR 33.5-67 days). One of the three cases who relapsed cleared Candida BSI after removal of a cardiac implantable electronic device (CIED). At one year of follow up, all six patients with complicated Candida BSI were alive.

Conclusions: The prevalence of complicated Candida BSI, including ocular involvement, is low. Further evaluation for hematogenous seeding may be warranted in recurrent episodes of Candida BSI.

**Abstract 4997**

**Risk factors for treatment failure in patients with deep spinal SSI with foreign bodies treated with debridement, antibiotic and implant retention (DAIR): an international multi-centre retrospective cohort study**

Raf Mens¹, Miranda Van Hoof², Robert Jan Kroeze¹, Yvonne Achermann³, Steven Maurer², Rosa Escudero Sánchez⁴, Javier Cobo Reinoso⁴, Pierre Tattetin⁵, David Luque Paz⁶, Mauro Salles⁷, Julie Lourtet Hascoet⁸, Tobias Kramer⁹,¹⁰,¹¹

¹Sint Maartenskliniek, Department of Orthopedic Surgery, Nijmegen, Netherlands, ²University Hospital Zurich, Zurich, Switzerland, ³Orthopedic University Hospital Balgrist, Zurich, Switzerland, ⁴University hospital Ramón y Cajal, Madrid, Spain, ⁵Pontchaillou University Hospital, Rennes cedex, France, ⁶CHU de Rennes, Rennes, France, ⁷Hospital da Irmandade da Santa Casa, São Paulo, Brazil, ⁸Saint Joseph Hospital, Spine Center, Paris, France, ⁹Charité Universitätsmedizin Berlin, Institute for hygiene and environmental medicine, Berlin, Germany, ¹⁰Charité Universitätsmedizin Berlin, National Reference Center for the Surveillance of Nosocomial Infections, Berlin, Germany, ¹¹LADR, Dr. Kramer & colleagues, Geesthacht, Germany

**Abstract third-party references:** ESCMID Study Group on Implant Associated Infections (ESGIAI)

**Background:** Deep spinal infections in patients with foreign bodies are a frequent complication. Best treatment strategies have not been evaluated, yet. Complete exchange of foreign bodies is infrequently performed. Debridement, antibiotic and implant retention (DAIR) is most frequently chosen as a treatment strategy. However risk factors for failure when performing DAIR without exchanging the implant have not yet been well studied. The objective of this study is to identify risk factors associated with failure in patients treated with DAIR.

**Materials/methods:** All consecutive cases of patient with a deep SSI between 2005-2015 treated with DAIR were included. Patients were at least 18 years of age at onset of SSI and had a follow up after initial DAIR for at least 12 months. Infections were defined as onset of symptoms and or clinical diagnosis of SSI after implant placement: Early onset infection (< 30 days); late infection infection (> 30days and < 365 days) and delayed onset (≥ 1 year). Failure was defined as either progressed, relapse or new infection within the follow up period.

**Results:** This study included 133 patients (57.5% female, median age 54) from 8 centers located in Europe and south-America. 112 (84.2%) patients had an early, 12 (9.0%) a late and 9 (6.8%) patients had delayed onset of infection. Median length of primary surgery until onset of SSI was 16 days (IQR: 10-23). Polymicrobial infections were identified in 50 patients (37.6%), *Staphylococcus aureus* was identified in 44 patients (MRSA=6), followed by 31 coagulase-negative staphylococci (19 meticillin resistant). *Enterococcus* spp. was identified in 22 patients. Of those, 33 patients failed (24.8%) during follow up, thereof 26 (19.5%) due to uncontrolled spinal infection; 6 due to relapse of infection with the same pathogen (4.5%) and one patient (0.8%) had a new infection with a different microorganism. Failure was most frequent in delayed infections (8 of 9, 88.9%).

Regression analysis of independent risk factors for failure of DAIR is pendent.

**Conclusions:** DAIR appears to be an effective strategy in spinal deep SSI associated with foreign bodies. Further studies are needed to evaluate strategies for patients at risk for failure.

Abstract 4998

**Donor selection in the Belgian Ghent Stool Bank: a relief to help**
Hannelore Hamerlinck*1, Jen Vandevijver1, Evelien Naessens1, Stien Vandendriessche1, Liselotte Coorevits1, Jerina Boelens1, Bruno Verhasselt1

1Ghent University Hospital, Department of Laboratory Medicine, Gent, Belgium

**Background:** The Ghent Stool Bank was created in 2018 at Ghent University Hospital, Belgium, to meet the growing demand of stool from healthy donors for fecal microbiota transfer. Candidate donors are selected based on a questionnaire inquiring general health, bowel movements, (chronic) diseases, medication. Selected donors are asked to provide 5 donations during 1 month. Every donation is tested for several enteropathogenic bacteria, viruses and parasites, as well as multi-resistant organisms in close accordance with the guidelines published by the Belgian Superior Health Council. Serum is screened before and 3 months after donations for hepatitis A, B, C, E; HIV; CMV; EBV and Treponema pallidum antibodies.

**Results:** Since the summer of 2018 until October 2019 approximately 264 candidate donors volunteered for stool donation at the Ghent Stool Bank. Based on general criteria, 166/264 candidate donors received a questionnaire and of those 51 passed selection for donations (immediately or after waiting period). Seven candidate donors never donated due to various reasons (lost to follow-up, diarrhea). 44 candidates started donating for a total of 190 donations (128 ± 81 g/donation), 19 men and 25 women. 43/44 donors tested positive for EBV IgG and 15/44 for CMV IgG. In 4 donors ESBL producing Escherichia coli, in 1 donor Stenotrophomonas maltophilia, in 1 donor Pseudomonas putida and in 1 donor Trichosporon was cultured from stool, their donations were excluded. 2/44 donors were rejected based on stool morphology (severe diarrhea). 7/42 tested positive for Hepatitis E IgG before the donations but the virus could not be detected in the stool samples by qPCR. 2 donors only tested positive for Hepatitis E IgG after the donations and might have suffered a recent infection, these donors were rejected as well.

**Conclusions:** In total 34 donors were fully approved on a total of 264 individual reactions, a success rate of 12.9%.

Figure 1: Overview of the selection process of the Ghent Stool Bank (GSB) in 2018 and 2019. Of 264 candidates 34 donors were approved, a success rate of 12.9%. (Q = questionnaire)

Abstract 5000

Molecular detection of Lyme disease and Q Fever agents in Dermanyssus gallinae (Acari: Mesostigmata) mites related to outbreaks of dermatitis in city-dwellers (southern Italy)

Donato Antonio Raele1, Domenico Galante1, Nicola Pugliese1, Giovanna La Saldandra1, Michele Lomuto1, Maria Assunta Cafiero*

1Istituto Zooprofilattico Sperimentale Della Puglia E Della Basilicata, Foggia, Italy

Background: The poultry red mite (PRM), Dermanyssus gallinae is a non-burrowing haematophagous nest-dwelling ectoparasite of birds; occasionally, it bites mammals, including humans also inducing papular dermatitis. Attacks are common in poultry workers but evidences show an increasing of urban infestations, due to presence of avian nests close to edifices and/or canarians/rodents taken as pets. The possibility that this ectoparasite may be also involved in transmission of human pathogens represents an additional medical concern; however, information is scarce with a one only documented case showing Bartonella quintana in Dermanyssus sp. mites collected during an urban outbreak of trench fever. Aim of this study was investigate for zoonotic agents PRMs involved in urban outbreaks of dermatitis.

Materials/methods: PRMs related to indoor infestations (2001-2017 years) in residentials were pooled on the basis of each outbreak and molecularly investigated for Coxiella spp. (16S rRNA), Chlamydophila spp. (16S rRNA), Rickettsia spp. (17 kDa protein-encoding gene), Bartonella spp. (16S–23S rRNA intergenic spacer) and Borrelia burgdorferi sensu lato (groEL gene). Amplicons were sequenced and nucleotide sequences compared to GenBank using BLAST.

Results: A total of 98 mites divided in 12 pools (size = from 5 to 10 mites) were tested. Out of 12 examined pools, one pool (1/12) resulted positive to Coxiella sp, two (2/12) to B. burgdorferi sensu lato and 9 (9/12) pools resulted negative. The obtained three amplicons exhibited 100% identity with Coxiella burnetii and 99% with Borrelia afzelii, respectively.

Conclusions: Among the parasites affecting synantropic birds, mainly pigeons, D. gallinae represents the principal ectoparasite that humans may acquire; feral birds/rodents are also reservoirs of a number of microorganisms, including Q fever and Lyme disease agents (DNA) for the first time herein documented in association with the PRMs. Although no study has yet been carried out to ascertain the ability of D. gallinae to transmit the detected pathogens to humans, this possibility should be no longer be neglected and previous PRM-infestations should be considered when atypically outbreaks occur in people with unlikely exposure to historical infection sources (ruminants and ticks, respectively).

How to accelerate bacteria identification from positive blood culture in a routine microbiology laboratory with the aid of MALDI-TOF MS: a simple and rapid in-house protocol

Patricia Orlandi Barth, Andrea Celestino De Souza, Larissa Lutz, Eliane Wurdig Roesch, Valério Aquino, Dariane Castro Pereira

1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, 4Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Abstract third-party references: Hospital de Clínicas de Porto Alegre

Background: Rapid diagnostic tests for infectious disease can lead to rapid optimization of antimicrobial therapy and subsequently improve patient outcomes. Although various methods have been developed to directly identify bacteria from positive blood culture by MALDI-TOF MS, it is necessary to develop a feasible protocol to be used in the routine microbiology laboratory. The aim of this study was to develop an even faster, simple and inexpensive in-house protocol for direct identification of bacteria from positive blood cultures.

Materials/methods: The study included hemocultures flagged as positive by bacT/ALERT®. A total of 134 bacterial samples isolated from blood cultures were obtained, 82 Gram-negative (GN) and 52 Gram-positive (GP) aerobes from August to November 2019. Rapid identification was performed as follow: 3 mL of blood was taken from positive bottle and transferred to a tube containing plasma separation gel and centrifuged [3,000 rpm/10 minutes]. After discarding the supernatant, 3 mL of saline was added and centrifuged [3,000 rpm/5 minutes]. The supernatant was discarded and 1uL was used for identification by the VITEK MS® system database v3.0 (bioMérieux, France); CHCA matrix solution was placed onto each spot and formic acid was added for samples with GP bacteria. Duplicate spots were generated for every sample. As a calibration control, the Escherichia coli ATCC 8739 strain was used. The rapid identification results were compared to those Vitek MS® results according to the manufacturer’s instructions protocol.

Results: The percentages of total correct identification of the isolates tested at species and gender level using rapid protocol were 95% and 96%, respectively, the highest identification rate at species level was for GN bacteria, 98% [81/82 were identified correctly] and for GP was 90%. No identification was obtained in only five isolates tested.

Conclusions: The in-house protocol could identified common bacteria directly from the blood samples within 30 minutes. The protocol could reduced the turn-around time at least 24h for bacteria identification in institution's workflow. This rapid method can be used to rapidly, simply, accurately and cost-effectively identify aerobic bacteria from positive blood cultures meeting the demand for rapid diagnostics tests.

Background: Climatic factors\(^1\, 2\) may explain proportions of antimicrobial resistance (AMR) variance across Europe and in the USA. Yet, they showed poorer explanatory strength for regions with higher levels of nurse emigration. The present study investigated the contribution of healthcare workforce density to AMR variance explanation in Europe.

Materials/methods: A 30-country database observational study was conducted. The six-year prevalence of carbapenem-resistant gram-negatives (CRGN; \textit{Pseudomonas aeruginosa}, \textit{Escherichia coli}, \textit{Klebsiella pneumoniae}, and \textit{Acinetobacter} spp.) was determined using published data\(^3\). Furthermore, we calculated the fluoroquinolone (FRGN) and aminoglycoside (NRGN) resistance prevalence in these same species in addition to methicillin-resistant \textit{Staphylococcus aureus} (MRSA) and vancomycin-resistant enterococci (VRE). Multivariate regression analysis was performed to identify associations between \(\log_{10}\) CRGN and healthcare workforce (density of nurses and of physicians), in addition to factors which might confound this association.

Results: We found a significant association of nurse but not physician density with CRGN, in contrast to FRGN, NRGN, MRSA and VRE, explaining 83\% of total variance (multivariate model). Nurse-density had a higher contribution to variance explanation than outpatient antimicrobial use (DDD). This association was not confirmed in countries with an established gate-keeping role of primary care specialists. In countries without gate-keeping, nurse-density was a significant explanatory factor of CRGN variance, contributing 72\% to total variance explanation. Using these models, we estimated the influence of nurse graduation figures on CRGN in 29 countries.

Conclusions: This study contributes to the AMR debate by identifying a potential association between nurse-density and CRGN. Statistical observation might be supported by survey data on health workers’ attitudes, which identified nurses and associates as the professionals most likely to perform hand hygiene\(^4\). Including nurses in future AMR policies is most beneficial in countries without a gate-keeping system. The findings are especially relevant, since nurses are largely missing in the EU Commission’s action plan on AMR\(^5\).

Abstract 5008

**Exploring minocycline pharmacodynamics against *Acinetobacter baumannii* and *Staphylococcus aureus* in a lung model in neutropenic mice: clinical implications on optimal dosing regimens**

Aart Van Der Meijden1, Wendy Kloezen1, Heleen Van Der Spek1, Marian Ten Kate1, Johan W. Mouton1, Anouk Edwina Muller1,2, Joseph Meletiadis1,3, Sanne Van Den Berg*1

1Department of Medical Microbiology and Infectious Diseases, Erasmus MC University Medical Centre Rotterdam, Rotterdam, Netherlands, 2Department of Medical Microbiology, Haaglanden Medical Centre, The Hague, Netherlands, 3Clinical Microbiology Laboratory, Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

**Background:** The emergence of multi-drug resistance has increased the interest on neglected and disused antibiotics like minocycline. Given the lack of knowledge on minocycline pharmacokinetics (PK) and pharmacodynamics (PD), we determined the PK/PD of minocycline in a lung infection model in neutropenic mice and bridged these data with human PK to optimise dosing regimens.

**Materials/methods:** Neutropenic mice were intranasally challenged with *A. baumannii* or *S. aureus* strains. Treatment was started 2h after infection and continued for 24h. PK was determined for 4 subcutaneous doses of 1-64 mg/kg using a validated liquid chromatography mass spectrometry method. PD studies of minocycline administered 0.5-64 mg/kg every 6h (q6h) were performed against 4 *A. baumannii* or 4 *S. aureus* strains. Mice were euthanized 24h after start of treatment and CFUs in lung homogenates were counted. Area under concentration-time curve (AUC) over MIC ratios to reach 1-log10 kill were estimated and the target attainment for 100, 200 and 300 mg q12h dosing regimens attaining a mean±SD AUC0-24 of 72±53, 183±33, 292±25 mg*h/L, respectively in patients was used in Monte Carlo Simulations (Fagan et al. Stroke 2010).

**Results:** Mean±SD AUC0-24/MIC ratio of minocycline resulting in 1-log10 killing at q6h dosing was 43.8±8.5 and 16.5±3.7 for *A. baumannii* and *S. aureus*, respectively. For *A. baumannii* this target was attained in >95% of cases for isolates with MICs ≤0.25, 0.5-2 and 4 mg/L with the 100, 200 and 300 mg q12h dosing regimen, respectively (Figure). For strains with MIC ≥8 mg/L, doses >300 mg are required. For *S. aureus*, >95% target attainment was reached for isolates with MICs ≤1, 2-4 and 8 mg/L with the 100, 200 and 300 mg q12h dosing regimen, respectively (Figure). Doses >300 mg are required for strains with MIC ≥16 mg/L.

**Conclusions:** The standard dose minocycline is sufficient to attain the PK/PD target for wild type *S. aureus* (MICs ≤0.25 mg/L). In contrast, for wild type *A. baumannii* (MICs 0.5-16 mg/L), the standard dosing regimen minocycline is not sufficient to attain the PK/PD target. Higher doses up to 300 mg are needed for *A. baumannii* strains with MICs up to 4 mg/L.

Abstract 5009

Pharmacokinetic variability and target attainment of fluconazole in critically ill patients

Ruth Van Daele*1,2, Joost Wauters3,4, Roger Brüggemann5,6, Raphaël Denooz7, Marie-Pierre Hayette8, Yves Debaveye9,10, Isabel Spriet1,2

1Katholieke Universiteit Leuven, Clinical Pharmacology and Pharmacotherapy, Leuven, Belgium, 2UZ Leuven, Pharmacy Department, Leuven, Belgium, 3Katholieke Universiteit Leuven, Laboratory for Clinical Infectious and Inflammatory Disorders, Leuven, Belgium, 4UZ Leuven, Medical Intensive Care Unit, Leuven, Belgium, 5Radboud University Medical Center, Department of Pharmacy and Radboud Institute for Health Sciences, Nijmegen, Netherlands, 6Radboud University Medical Center, Expertise in Mycology Radboudumc / CWZ, Nijmegen, Netherlands, 7CHU Sart-Tilman, University of Liège, Laboratory of Clinical, Forensic, Environmental and Industrial Toxicology, Liège, Belgium, 8University of Liège, Laboratory of Clinical Microbiology, Centre for Interdisciplinary Research on Medicines (CIRM), Liège, Belgium, 9Katholieke Universiteit Leuven, Laboratory of Intensive Care Medicine, Leuven, Belgium, 10UZ Leuven, Intensive Care Unit, Leuven, Belgium

Background: Fluconazole is an antifungal drug frequently used in the intensive care unit (ICU) but few data are available regarding its exposure in this population. A subanalysis of the DALI-study raised some concerns considering variability in exposure and inadequate target attainment in critically ill patients. We aimed to determine fluconazole variability and target attainment at the ICU.

Materials/methods: All adult, critically ill patients treated with intravenous fluconazole between May and September 2019 were included, provided that the DNR code was <2 and written informed consent was obtained. The administered dose was left at the discretion of the treating clinician. Trough samples were collected during a maximum period of 15 days. Samples were analysed using an UPLC-DAD analytic method. The intra-and intersubject variability of fluconazole trough concentrations was calculated by dividing the standard deviation by the mean*100. Moreover, the difference between the maximum and minimum fluconazole concentration within each patients was determined. For target attainment, the fAUC/MIC from clinical data amounts to 100 corresponding with trough levels >10-15 mg/L, as recommended by EUCAST and ECIL-6. The limit for toxicity was set on 50 mg/L.

Results: Seventeen patients were included, resulting in 95 fluconazole trough levels. Patients had a median APACHE-II score of 18 [16-23] and administered dose of 5.1 [4.1-7.5] mg/kg/day. The median fluconazole trough level was 26.6 [19.7-35.3] mg/L. In Figure 1, fluconazole trough concentrations are depicted in function of the dose. The mean intra-and intersubject variability (CV%) were 18,4% and 34,5%, respectively. The median difference between the maximum and minimum concentration for the 14 patients with >1 measured fluconazole level, was 14,8 [6,6-18,9] mg/L. In two patients, this difference was more than 2-fold. All trough levels were >10mg/L and 85/95 (89%) samples were >15mg/L. None of the levels exceeded the upper limit of 50 mg/L.

Conclusions: As shown in the DALI-study, a considerable intra-and intersubject variability in fluconazole levels was observed at the ICU. Despite this variability, all fluconazole trough levels were above the lower limit of 10 mg/L and most of them >15 mg/L. No toxic concentrations were observed.

Enterovirus surveillance in an Italian paediatric hospital

Livia Piccioni1, Stefania Ranno1, Luana Coltella1, Cinzia Auriti2, Giuseppe Pizzichemi1, Stefano Chiavelli1, Laura Lancella3, Laura Cursi3, Carlo Concato*1

1Bambino Gesù Children’s Hospital, IRCCS, UOC Microbiology, Virology and Parasitology, Rome, Italy, 2Bambino Gesù Children’s Hospital, IRCCS, Neonatal Intensive Care Unit, Rome, Italy, 3Bambino Gesù Children’s Hospital, IRCCS, Pediatric and Infectious Diseases Unit, Rome, Italy

Background: Human Enteroviruses (EVs) are classified into four groups (A-B-C-D) including polioviruses and non-polioviruses. EVs are ubiquitous and a common cause of self-limiting febrile, gastroenteric or respiratory illnesses. Some EV genotypes are also responsible for serious diseases; in infants and young children. EVs can cause meningoencephalitis, paralyis, myocarditis, sepsis-like syndrome, respiratory disease and acute hepatitis. Since EV can be neurotropic and responsible for severe infections, it is necessary to monitor and to genotype it in order to correlate the EV types to the different clinical manifestations.

The aim of the study is EV surveillance to identify genotypes associated with more severe conditions, to confirm the absence of circulation and importation of the poliovirus, to monitor their molecular epidemiology and distribution and to facilitate a correct patient management.

Materials/methods: Since January 2018, we have been collecting positive samples for EV from patients admitted to the Bambino Gesù Children’s Hospital in Rome [Italy]. Up to now, sequencing part of the VP1 capsid protein gene of EV according to WHO recommendations, we have genotyped 45 Enteroviruses from: 15 cerebrospinal fluid, 14 plasma, 12 respiratory, 3 stool and 1 skin swab samples. Samples were collected from 40 children mostly younger than 1 year old [30/40].

Results: In our population, we have genotyped 20 echoviruses [6, 7, 9, 11, 18, 20, 25, 30], 14 coxsackieviruses [A6, A9, A16, B1, B2, B4, B5] and 6 enteroviruses [A71 and D68]. In particular, in patients younger than 1 year old [18/30] had meningeal symptoms attributable to echoviruses [7, 9, 11, 18, 20, 25 and 30], coxsackieviruses [A9, B4 and B5] and Enterovirus A71. Patients older than 1 year old [10/40] had mostly respiratory infections [8/10]. Only one of these patients [6 years old] had a diagnosis of meningitis due to Echovirus 6.

Conclusions: From these initial results, no epidemic outbreaks due to EV was found. With few exceptions, genotype detected were consistent with symptomatology reported on literature data. We hope that a greater number of typed EVs, will allow to establish an etiological correlation with the pathology for those genotypes for which it has not yet been described.

Abstract 5013

Melioidosis in an Indian intensive care unit: the enigma of a ‘Silent Killer’

Tushar Shaw*, Vandana Kalwaje Eshwara, Chiranjay Mukhopadhyay

1Manipal Academy of Higher Education, Kasturba Medical College, Manipal, Manipal, India, 1Manipal Academy of Higher Education, Kasturba Medical College, Manipal, Manipal, India

Abstract third-party references: Kasturba Medical College, Manipal Academy of Higher Education, Manipal

Background: Melioidosis is a neglected tropical disease in India and accounts for 2-5% of all patients admitted with Community-acquired sepsis. Recent modeling on the global distribution of melioidosis predicted India to have the highest burden of the disease with an incidence of 52506 cases per year. A study from Thailand found 74% of patients undergoing sepsis (SOFA≥2), with melioidosis being the second most common cause of infection. We undertook the study to determine the clinical characteristics and outcome of patients with severe melioidosis undergone sepsis.

Materials/methods: A prospective ICU based observational study from January 2014 to November 2017 was conducted in a tertiary care hospital in India. Patients diagnosed with culture confirmed melioidosis admitted to the ICU with SOFA score >2 were recruited in the study. Comparisons of continuous variables between survivors and nonsurvivors were performed using the Mann-Whitney U test. Categorical variables were compared using χ² test or Fisher Exact Test.

Results: Forty-one adult ICU patients with microbiologically documented melioidosis were included in the study. Mean age was 51.2 ± 15.2 years with male predominance (4:1). 18 (43.9%) of the cases were associated with occupation related to soil contact. Majority of the patients were bacteremic (30/41; 73.2%) having a median Pitt Bactermia score of 3 (1-5). Pneumonia was the most common presentation (25/42; 61%) with a median CURB 65 score of 2 (1-4). 19 (46.3%) of the patients underwent Acute Kidney Injury and 8 (19.5%) were in septic shock. 5 (12.1%) patients underwent organ failure with median of 2 organ dysfunction. 31 (75.6%) of the cases had Type 2 Diabetes Mellitus. Median APACHE II score was 19.5 (14-26). The overall mortality was 29.3%. The median ICU length of stay for survivors and non survivors was 6 days and 5 days, respectively. Organ failure (OR 26.5; CI 3.8- 183.7, p<0.001) and Pitt Bacteremia score >4 (OR 2.8; CI: 1.0-7.8, p=0.03) were significant risk factors associated with mortality.

Conclusions: Death being predicted by organ dysfunction and higher PITT Bacteremia score signifies the poor outcome of melioidosis patients undergone sepsis. An earlier and rapid diagnosis of the disease to avoid systemic involvement is a requisite.

Mycobiome sequencing reveals a high fungal diversity in patients with severe atopic dermatitis

Bettina Schmid1,2, Eugen Bersuch1, Axel Künstner1, Anke Fähnrich3, Hauke Busch1, Martin Glatz1,2, Philipp Bosshard1,2

1University Hospital Zürich, Department of Dermatology, Zurich, Switzerland, 2University of Zurich, Zurich, Switzerland, 3University of Lübeck, Lübeck, Germany

Background: Atopic dermatitis (AD) is a multifactorial, chronically relapsing inflammatory skin disease. Characteristics are an impaired skin barrier and an altered skin immune system, which often come along with predominant colonization by Staphylococcus aureus. The role of fungi, i.e. the mycobiome, remains poorly investigated although AD patients are frequently sensitized to Malassezia, the most abundant fungus on skin. We aim to improve the understanding of the skin mycobiome in AD.

Materials/methods: Skin swabs of 11 AD patients and 11 healthy controls (HC) were taken from 4 skin sites (antecubital crease, glabella, vertex, and dorsal neck). To assess temporal shifts in the mycobiome, AD patients were sampled at 3 time points (0, 2 and 4 weeks). HC were sampled at 2 time points (0 and 4 weeks). We assessed the relative abundance of fungal genera and species by amplicon-based next-generation sequencing (NGS) of the fungal ITS1 region.

Results: The most abundant fungi at all skin sites were Malassezia spp. The species distribution was site-dependent with high abundances of M. globosa at the neck, M. restricta at the glabella and vertex, and overall lower abundance of Malassezia at the antecubital crease. As shown exemplary for the neck (figure 1), patients with severe AD tended to be more frequently colonized with non-Malassezia fungi such as Candida. In most HCs and patients with mild to moderate AD, the mycobiome was comparable between individuals and stable over time. In contrast, in severe AD the mycobiome was different between individuals and changed over time.

Conclusions: Patients with severe AD had a high intra- and interpersonal species diversity. We speculate that the impaired skin barrier in severe AD allows colonization with more different fungi than healthy skin. Vice versa, the altered mycobiome may cause activation of the skin immune system leading to inflammation and eczema. In the next step, we will correlate these results with the bacterial microbiome in the same samples.

Figure 1: Relative abundances of fungal taxa in swabs collected from the neck in a) severe AD, b) mild to moderate AD, and c) HCs. t1: day 0; t2: day 14; t3: day 28

Human parechovirus 3 “outbreak” at a tertiary hospital

Mikel Urrutikoetxea-Gutierrez*, Manuel Imaz Perez1, Borja Elgoibar Alvarez2, Joseba Iñaki Rementeria Radigales3, María Cabrerizo4, José Luis Díaz De Tuesta1

1Basurto University Hospital (Microbiology Department), Osakidetza, Bilbao, Spain, 2Cruces University Hospital (Pediatric Department), Osakidetza, Bilbao, Spain, 3Basurto University Hospital (Pediatric Department), Osakidetza, Bilbao, Spain, 4Carlos III Health Institute, Madrid, Spain

Background: Human parechoviruses (HPeV) remain as one of the most prevalent pathogens causing fever without a source, sepsis-like illness and meningitis/encephalitis in neonates and children under 3 months of age. Most of these cases are caused by HPeV3. The objective of this study was to describe a limited outbreak of the HPeV3 infections in our sanitary area attending a pediatric population of 55000.

Materials/methods: HPeV detection was conducted on SmartCycler® with a Progenie-Molecular® assay and the positive samples were sent to Instituto de Salud Carlos III for further typing by VP3/VP1 sequencing. We reviewed the clinical records in search of clinical manifestations and biochemical findings and antibiotic prescriptions.

Results: We identified 9 HPeV-positive patients between May and July 2019. All HPeV were typed as HPeV3. Mean age was 242 days, but the median was 51 days. The most frequent sample where HPeV3 was detected was whole blood (7), followed by nasopharyngeal swab (6), feces (4) and cerebrospinal fluid (CSF) (3). Eight children were diagnosed of fever without source, only two of them had leukocytosis (> 10000/µl) and an elevated plasmatic reactive protein C (>5 mg/L). None of them received antibiotic treatment. One of these patients presented a macular rash. None of them developed neurological symptoms during the acute illness or to the present day. One patient was diagnosed of clinical sepsis and received antibiotic therapy, but it was suspended shortly after obtaining the HPeV3 positive result. None of these nine patients had any other microbiological findings during the episode.

The CSF-biochemistry of the 3 patients with positive CSF samples was anodyne with no alterations at the leukocyte count or protein levels.

Conclusions: Almost half of the patients of our study were older than 3 months, the usual risk group to get HPeV3 infections. In our study whole blood seems to be an adequate sample for detecting HPeV3. HPeV3 detection at CSF can’t be ruled out even without biochemical alterations. The short span of time in which all cases appeared and the lack of other cases during the rest of this year cases suggest an epidemiological relationship between these cases.

Abstract 5017

Fibronectin binding protein plays pivotal role in development of central nervous system complication of *Staphylococcus aureus* bacteremia

Chung-Jong Kim*, Kyoung-Ho Song, Chang Kyung Kang, Eu Suk Kim, Ji Yun Bae, Hee Jung Choi, Youngehee Jung, Wan Beom Park, Nam Joong Kim, Myoung-Don Oh, Hong Bin Kim

1Ewha Womans University Seoul Hospital, Seoul, South Korea, 2Seoul National University Bundang Hospital, Seongnam, South Korea, 3Seoul National University Hospital, Seoul, South Korea, 4Hallym University Sacred Heart Hospital, Anyang, South Korea

**Background:** Central nervous system complications (CNS-C) in patients with *Staphylococcus aureus* bacteremia (SAB) are one of the most serious complications. Until recently, no microbiologic factors related to CNS-C have been known. The purpose of this study was to explore the microbiologic factors associated with CNS-C in SAB.

**Materials/methods:** Clinical isolates and their clinical data of SAB in four university-affiliated hospitals were collected. CNS-C were defined as any of multiple embolic infarctions, intracranial hemorrhage, or meningitis. Control cases without CNS-C were matched to the cases according to the methicillin susceptibilities, site of infection, and severity defined by SOFA score. All cases and control patients underwent the brain magnetic resonance imaging or computed tomography. We performed the polymerase chain reaction to detect virulence factors, sequencing of fibronectin binding protein A (fnbpA) to find single nucleotide polymorphisms (SNP), and multilocus sequence type analysis.

**Results:** A total of 1087 cases of SAB were occurred during the study period during 5 years. CNS-C occurred in 43 patients (4.0%). Embolic infarction accounted for 23 cases, intracranial hemorrhage, for 8 cases, and both lesions were present in 12 cases. Of these cases, experimental study was performed using 22 isolates that were stored, with isolates of their matched control cases. FnbpA was significantly higher in isolates from CNS-C, whereas fibronectin binding protein B (fnbpB) was associated with lower incidence of CNS-C. Other virulence factors did not significantly differ between two groups. In the SNP analysis of fnbpA, K786N mutation significantly increased the incidence of CNS-C. CC5 and CC30 strains were significantly associated with CNS-C, and CC30 with variant fnbpA had a high rate of CNS-C.

**Conclusions:** The presence of fnbpB was negatively associated with CNS-C in SAB. However, the presence of fnbpA was associated with CNS-C of SAB. Moreover, genetic variation in fnbpA raise the risk of CNS-C in SAB.

Abstract 5018

The use of carbapenemase real-time PCR directly from rectal swab for control carbapenem-resistant Enterobacteriaceae cross-transmission in a kidney transplant ward

Maristela P. Freire*1, Ana Paula Cury1, Doroti Garcia1, Fernanda Spadao1, Walkiria C. G. Valentin2, Flavio Jota De Paula3, Flávia Rossi4, Elias David Neto5, William C. Nahas4, Ligia Pierrotti5

1Clinical Hospital, Infection control committee, São Paulo, Brazil; 2Clinical Hospital, Central Laboratory Division, São Paulo, Brazil; 3Adolfo Lutz Institute - Central, São Paulo, Brazil; 4Clinical Hospital, Kidney Transplant Service, São Paulo, Brazil; 5Clinical Hospital, Infectious Disease Department, São Paulo, Brazil

Abstract third-party references: Conselho Nacional de Desenvolvimento Científico e Tecnológico

Background: Infection by Carbapenem resistant Enterobacteriaceae (CRE) is a great concern among solid organ transplant recipients. CRE colonization is the main risk described for CRE infections in this population.

The aim of this study was to analyze the impact of the introduction a CRE-surveillance based on real-time PCR for carbapenemases in a kidney transplant ward.

Materials/methods: We observed an increase on cases of CRE-acquisition related to KT-ward stay in the second semester-2018 (Figure). The strategies for CRE control adopted in this unit before and during intervention period were: CRE surveillance through rectal swab culture (SC) at admission and on a weekly basis; CRE-colonized patients cohorting; periodical staff training for hand-hygiene (HH), and monthly report consumption of alcohol-based hand sanitizer. The intervention occurred from March-2019 to October-2019 and consisted on collected second rectal swab during weekly surveillance. We tested in this swab carbapenemases genes (\textit{bla}\textsubscript{KPC}, \textit{bla}\textsubscript{NDM}, \textit{bla}\textsubscript{VIM} and \textit{bla}\textsubscript{IMIP}) by real-time PCR directly from swab. The results were available in the same day and patients with positive results were put on contact precaution. We analyzed the correlation between tests (real-time PCR and SC) through Kappa test, and the evolution of rates during the time through chi-square for trend.

Results: A total of 257 patients collected 518 paired SC (PCR and culture) for CRE during study period. Positivity rate of cultures was 13.2%, 34 patients. Eleven patients (11/34-32.4%) had CRE also isolated in clinical cultures, among those, 8 (8/34-23.5%) developed infection. The number of patients with positive RT-PCR in rectal swab was 46 (16.7%). Fourteen patients (14/46 – 30.4%) had positive PCR and negatives surveillance/clinical cultures. The tests agreed (PCR and SC) on 90.3%, Kappa coefficient of 0.60. The most common CRE isolated was \textit{K. pneumoniae} 85.3% [29/34] and the most common carbapenemase was \textit{bla}\textsubscript{KPC}, 80.4% [37/46].

We observed a progressive decrease on positivity rate of patients who the acquisition of CRE was related to KT ward stay (Figure) from 15.0% to 4.9% (p=0.05), the unit colonization pressure rate also decreased from 24.0% to 12.2% (P=NS) during study period.

Conclusions: Surveillance culture through real-time PCR could be an additional strategy for CRE control.

West Nile virus 2018 season in Italy: rapid spreading of West Nile neuroinvasive disease in northwest Italy

Elisa Burdino*, Tiziano Allice1, Maria Grazia Milia3, Gabriella Gregori4, Giulia Morleo1, Raffaella Cipriani1, Chiara Pasqualini2, Pierangela Ferrero2, Valeria Ghisetti1

1Hospital Amedeo di Savoia, Laboratory of Microbiology and Virology, Torino, Italy; 2SeREMI - SSEpi, SEREMI, Servizio di riferimento Regionale di Epidemiologia per la sorveglianza, la prevenzione e il controllo delle Malattie Infettive, Alessandria, Italy

Background: In Italy, results from the integrated-One-HEALTH-surveillance system reported, for the year 2018, 230 West Nile neuroinvasive disease (WNND) which are equivalent to 40% of all West Nile virus (WNV) notified, with 42 deaths (18%). It is a significant higher number of WNND compared to the previous period from 2008 to 2017 (231 cases in 9 years). The majority of WNND cases occurred in Northern areas along the Po river. We report results of the human WNV surveillance in Piedmont, North-West Italy, an area crossed by the Po river (4.424 million inhabitants) where the vector, mosquito Culex spp., is widespread. The first human case was notified by the regional Reference Laboratory, Amedeo di Savoia Hospital, Torin on July, 27 (50 days after the first Italian case in Rovigo, Italy North-East).

Materials/methods: From the 1st of June to 30th November 2018, 216 patients were studied with molecular methods for WNV-RNA detection in plasma, urine and cerebrospinal fluid (CSF) when available, (ELITechGroup, Italy), serology for WNV IgG and IgM (Euroimmun AG, Lubek, Germany), and confirmation with Plaque Reduction Neutralization Tests (PRNT).

Results: Autochthonous WNV infection was identified in 61 patients (28%, 54 confirmed and 7 probable cases). WNND was present in 41 patients (67%), West Nile fever (WNF) in 12 (19,7 %); 8 were symptom-less. The most frequent condition in WNND was encephalitis and/or meningitis/encephalitis (30 patients, 73%); 3 patients died (7.3%). Comorbidities were present in 29% of patients with WNND. RT-PCR identified WNV in 26 patients with WNND: in urine and/or plasma (24 patients), some of them with a prolonged viraemia and/or viruria (until 26-28 days); CSF was positive in 7. In the remaining patients WNV infection was confirmed by serology.

Conclusions: According to the 2018 season in Europe, we confirmed the early start of WNV season in North-West Italy and the rapid spread of WNND along the Po river valley, with an unusual high number of WNND that support a strict integrated One-HEALTH-surveillance system to predict areas and periods at risk of WNV outbreaks. Further studies are required to better understand genetic and viral determinants for WNND in naïve patients.

The resistance ratchet tightens: widespread penicillin-binding protein-3 insensitivity in carbapenemase-producing Escherichia coli

Shazad Mushtaq*, Matthew Ellington, Neil Woodford, David Livermore

1Public Health England, London, United Kingdom, 2University of East Anglia, Norwich, United Kingdom

Background: It is widely accepted that β-lactam resistance among Enterobacterales predominantly involves β-lactamases whereas resistance in Gram-positive bacteria predominantly reflects target Penicillin-Binding Protein (PBP) modification. Recent reports of PBP-3 changes in carbapenemase-producing E. coli [CPE. coli] challenge this dogma, but prevalence is unclear.

Materials/methods: Whole Genome Sequencing (WGS, by Illumina HiSeq 2500) was performed for CPE. coli submitted to PHE from Jan-2013 to Oct-2016: 97% were submitted between Jan-2014 to June-2016, when WGS was performed on CPE. coli from every new patient. Data were analysed for MLST type, resistance genes and pbp3 sequence using in-house tools. MICs were determined by BSAC agar dilution.

Results: Among 816 CPE. coli referred, from 58 hospitals, 121 (14.8%) had a 12-bp insert leading to insertion of 4-amino acid sequences in the turn between the β2b–β2c sheets of PBP-3: 110 had YRIN, 7 YRIK, 3 YRIP and 1 YTIN. Inserts were found in 67/276 (24.3%) isolates with blaNDM, 43/433 (9.9%) with blaOXA-48-like, 5/20 (25%) with both blaOXA-48-like and blaNDM, 4/68 (5.9%) with blaKPC, 1/1 with both blaOXA-48-like and blaKPC, 1/11 (9.1%) with blaVIM, but 0/3 with blaIMP and 0/3 with blaGES. Among 72 (67+5) insert-positive isolates with NDM, 44 had NDM-5 and 12 had NDM-7; among 49 (43+6) with OXA-48-like, 30 had OXA-181. Classical NDM-1 and OXA-48 dominated among insert-negative isolates. Isolates with inserts belonged to 36 STs, with ST410 (n=20, 16.5%), ST167 (n=12, 9.9%), ST940 (n=8, 6.6%) prominent. MICs that were stable to the carbapenemase produced and protected against co-produced ESBLs with avibactam, were raised for insert-positive isolates, illustrated by geometric means [tabulated].

<table>
<thead>
<tr>
<th>Antibiotic</th>
<th>Geometric mean MIC, mg/l (n, no. tested)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>OXA-48-like</td>
</tr>
<tr>
<td>Ceftazidime/avibactam</td>

</tr>
</tbody>
</table>

Conclusions: The wide distribution of these inserts in E. coli PBP-3, and their association with particular carbapenemases (NDM-5, -7 and OXA-181), not particular STs, is striking, as is the association with reduced susceptibility to PBP3-targeted antibiotics. The prevalence and cumulative effect of these mechanisms needs surveillance, for they have the potential to compromise otherwise promising agents.

Abstract 5022

Cefazolin meningeal diffusion compared to cloxacillin for the treatment of methicillin-susceptible Staphylococcus meningitis

Paul Le Turnier1, Matthieu Grégoire2,3, Guillaume Deslandes4, Karim Lakhal1, Deschanvres Colin1, Raphaël Lecomte1, Jean Philippe Talamin1, Vincent Dubee1, Ronan Bellouard2, David Boutoille1,8, Anne-Gaëlle Leroy9, Benjamin Gaborit*1,8

1University Hospital of Nantes, Department of Infectious Diseases and CIC 1413, INSERM, Nantes, France, 2University Hospital of Nantes, Clinical Pharmacology Department, Nantes, France, 3University of Nantes, UMR INSERM 1235, The enteric nervous system in gut and brain disorders, Nantes, France, 4University Hospital of Nantes, Clinical Pharmacology Department, Nantes, France, 5University Hospital of Nantes, Department of Anesthesiology and Intensive Care Medicine, Nantes, France, 6Centre hospitalier de Cornouaille, Internal Medicine and Infectious Diseases Department, Quimper, France, 7University Hospital of Angers, Department of Infectious Diseases, Angers, France, 8University of Nantes, EA 3826, Laboratory of clinical and experimental therapeutics of infections, IRS2-Nantes Biotech, Nantes, France, 9University Hospital of Nantes, Department of Bacteriology, Nantes, France

Abstract third-party references: On behalf of NAMAP study group

Background: Cefazolin is not recommended for the treatment of methicillin-susceptible Staphylococcus (MSS) meningitis contrary to anti-staphylococcal penicillins. However, the data supporting these recommendations are limited. The main objective of the study was to assess the meningeal diffusion of cefazolin and cloxacillin in patients treated for MSS meningitis.

Materials/methods: Patients with cerebrospinal fluid (CSF) concentrations of cefazolin or cloxacillin measured at a French University Hospital between January 2009 and October 2019 were retrospectively identified. Patients with proven MSS meningitis defined by a positive culture of CSF (at least two samples in case of coagulase-negative staphylococci) and/or a polymerase chain reaction (PCR) in CSF were included. Medical charts were retrospectively reviewed. Concentrations were measured in CSF and plasma using a liquid-chromatography coupled with mass-spectrometry assay. Bacterial antibiotic susceptibilities were determined using a Vitek 2 automated system (bioMérieux, France). CSF concentrations were analyzed with respect to the latest ECOFF values for cefazolin (≤ 2 mg/L) and cloxacillin (≤ 0.5 mg/L).

Results: Among the 18 included patients, 8 (44%) received cefazolin and 10 (52%) cloxacillin. Median daily dosages of cefazolin and cloxacillin were 8 (range 6-12) and 12 (range 10-13) grams respectively. All patients received continuous infusion. All plasma samples were collected on steady state. Twelve patients (67%) were males, median [IQR] age was 60 years [51;71], 14 (83%) had post-operative meningitis and 4 (22%) hematomatous meningitis. Median [IQR] antibiotic CSF concentration was 2.8 mg/L [2.1;3.8] and 0.7 mg/L [0.5;1.7] for cefazolin and cloxacillin respectively. CSF concentration of antibiotic was above ECOFF in 11/14 (79%) samples corresponding to 6/8 [75%] patients receiving cefazolin and 10/13 [77%] samples corresponding to 7/10 [70%] patients receiving cloxacillin. Median [IQR] CSF/plasma ratio was 4.3% [2.9;8.4] for cefazolin and 1.8% [1.7;2.2] for cloxacillin. Cefazolin was discontinued in 3 (30%) patients because of failure or under dosing and antibiotic therapy was switched. All patients in both groups were cured without any recurrence.

Conclusions: In patients treated for staphylococcal meningitis cefazolin appeared as satisfying as regarding the level of CSF diffusion. Treatment failure was only observed in cloxacillin group. Cefazolin should be prospectively evaluated in this indication.

Epidemiological typing of Neisseria gonorrhoeae with whole genome sequencing: a vital supplement in transmission surveillance

Karin Haij Bhattarai*1, Eva-Lena Ericsson1, Fredrik Dyrkell2, Dimitrios Arnellos3, Göran Bratt3, Måns Ullberg1, Niklas Björkström2, Hong Fang3

1Karolinska University Hospital, Clinical Microbiology, Stockholm, Sweden, 21928 Diagnostics, Gothenburg, Sweden, 3Stockholm South Hospital, Department of Infectious Diseases, Stockholm, Sweden

Abstract third-party references: 1928 Diagnostics, Stena Center 1D, SE-41 2 92 Gothenburg, Sweden, Department of Clinical Microbiology, Karolinska Institutet, SE-141 86 Stockholm, Sweden, Department of Infectious Diseases, Stockholm South Hospital, SE-118 83 Stockholm, Sweden

Background: Neisseria gonorrhoeae remains a global public health concern. While traditional methods for epidemiological typing of N. gonorrhoeae are suboptimal, whole-genome sequencing (WGS) offers ultimate discriminatory power in bacterial genotyping. Hence, this study aimed to assess the potential of N. gonorrhoeae genotyping as a tool in transmission surveillance.

Materials/methods: Forty-seven isolates from 35 patients enrolled in 17 suspected epidemiological linkages were investigated using whole-genome sequencing, as well as serogroup and serovar determination. The genetic relationship of the isolates was analyzed by N. gonorrhoeae multi-antigen sequence typing (NG-MAST), multi-locus sequence typing (MLST), core-genome MLST (cgMLST) and single nucleotide polymorphisms (SNPs) using the 1928D platform. Determination of SNPs was performed on isolates belonging to the two dominating sequence types (STs).

Results: Among the 47 isolates, 24 isolates were categorized into 13 NG-MAST genogroups and 23 isolates had novel types. Fifteen different STs were detected by MLST. ST9363 and ST8156 were predominant and accounted for 40.4% of all isolates. The combination of a novel NG-MAST (porB 2999, tbpB 267) and ST9363 was the most common type, identified in seven isolates from six patients belonging to four epidemiological linkages. The second most common combination was NG-MAST S441 with ST8156. In the cgMLST, >98% of the core genes were identified in all isolates. Of 13 epidemiological linkages, at least two isolates in each linkage were found to be strongly genetically related with the same MLST and 0-1 allelic differences with cgMLST. cgMLST also suggested five transmission events including two outbreaks with 0-4 differed alleles, where epidemiological data will be further investigated. SNP analyses revealed that four ST8156 cases in December 2018 to February 2019, were strongly genetically related (1-4 SNPs), in accordance to the cgMLST results. Only in nine epidemiologic linkages, grouping of isolates with serovar were concordant with grouping by sequence types.

Conclusions: WGS-based typing method provides a useful tool in epidemiological typing of N. gonorrhoeae. However, when selecting a typing method, it is essential to consider the epidemiological context and the question that the genomic data should answer. Therefore, genomic investigation should be used to supplement, rather than replace, careful epidemiologic investigation.

Abstract 5028

Acquired resistance to fosfomycin through acquisition of an ISEcp1-blaCTX-M-14 tandem in a Klebsiella pneumoniae clinical isolate

Nicolas Kieffer¹, Laurent Poirel*¹, Linda Mueller¹, Patrice Nordmann¹

¹University of Fribourg, Fribourg, Switzerland

Background: Acquired resistance to fosfomycin in Gram-negative bacteria may occur through chromosomal mutations or acquisition of genes encoding FosA-like enzymes that inactivate fosfomycin. Despite having a natural $\text{fosA}$ gene in its chromosome, Klebsiella pneumoniae isolates remain susceptible to fosfomycin, suggesting a low-level of expression of this gene in normal conditions. Our study aimed to decipher the genetic basis of fosfomycin resistance acquisition in a K. pneumoniae isolate recovered in Switzerland in 2017.

Materials/methods: The fosfomycin-resistant K. pneumoniae isolate with no known mechanism identified was submitted to whole genome sequencing and the resistome was studied using the CARD and ResFinder databases. Minimal inhibitory concentration (MIC) of fosfomycin was determined by agar dilution. Gene expression assays were performed by RT-qPCR. Cloning experiments were done using the plasmid pBADb carrying an L-arabinose inducible promoter.

Results: Isolate S54 presented an MIC of fosfomycin at 2,048 mg/L that dropped to 128 mg/L when phosphonoformate was added, suggesting the production of a glutathion-S-transferase. ResFinder and CARD databases did not identify any acquired fosfomycin resistance genes except the natural chromosomal $\text{fosA}$ gene. In-silico analyses identified an ISEcp1-bla-CTX-M-14 cassette inserted upstream of the natural $\text{fosA}$ gene providing a -35 box forming a novel hybrid promoter for $\text{fosA}$ expression. Once cloned in E. coli, the $\text{fosA}$ gene with this chimeric promoter had an MIC of fosfomycin at 2,048 mg/L, while the same construct but with a wild-type promoter was only at 128 mg/L. Quantitative expression experiments showed an overexpression of the $\text{fosA}$ gene of 340-fold between the two constructs.

Conclusions: We report here the acquisition of fosfomycin resistance by the acquisition of a strong hybrid promoter brought by the acquisition of an ISEcp1-bla-CTX-M-14 cassette. Hence, our study showed that acquired resistance to both cephalosporins and fosfomycin may occur through a single genetic event in K. pneumoniae.

Impact of letermovir (LTV) on utilisation of pre-emptive therapy for cytomegalovirus after allogeneic haematopoietic cell transplantation: a single-centre experience

Jiaqi Fang*1, Phaedon D. Zavras1, Qi Ni Su2, Anat Stern3, Tamara Nawar4, Miguel Perales2,3, Genovefa Papanicolaou1,3

1Memorial Sloan Kettering Cancer Center, Infectious Disease Service, New York, United States, 2Memorial Sloan Kettering Cancer Center, Bone Marrow Transplant Service, New York, United States, 3Weill Cornell Medicine, New York, United States

Abstract 5029

**Background:** Quantitation of antiviral utilization using Pre-emptive therapy (PET) strategy for CMV is important for assessing the net value of preventive strategies. We examined a contemporary cohort managed by PET to 1) quantify CMV antiviral utilization and 2) report readmissions related to CMV and 3) report net changes in PET days after Letermovir prophylaxis.

**Materials/methods:** Retrospective review of adult, CMV R+ HCT recipients of first peripheral blood or marrow HCT from 3/2013 to 12/2017 managed by PET (PET-group) and from 12/2017 to 12/2018 who received Letermovir prophylaxis (LTV-group). Ex vivo T-cell depletion (TCD) or unmodified graft from mismatched donors defined high CMV risk (HR). All others were low risk (LR); Routine monitoring was performed by CMV quantitative PCR assay. PET was initiated per standard of care. Clinical characteristics, PET and readmission through Day 180 were extracted from the electronic medical records/databases. Inpatient charges were obtained from the Vizient database and converted to adjusted costs using cost-to-charge ratio, wage index and inflation rate.

**Results:** PET group comprised 368 R+ recipients (HR 52%). Overall, 208 (57%) patients initiated PET (Figure 1a) at median of 35 days; Interquartile range (IQR): 28-41 post HCT for a median duration of 47 days (IQR:34-70) (Figure 1b). Of 11,759 total antiviral-days 8,943 (76%) were (val)Ganciclovir and 2816 (24%) Foscarnet; 80% of antiviral-days occurred <D100 and 18% were administered in-patient. 112/208 (54%) PET recipients were readmitted compared to 53/160 (33%) of No-PET recipients (p=0.00005). Of 180 readmissions among PET recipients 67 (37%) were CMV-related with an average total cost of $185,053; standard deviation (237,099). Of 98 patients in the LTV group, 5 (5.1%) received PET (figure 1c). PET utilization by D100 was compared to 95 patients that received HCT during 2017 and managed preemptively (No LTV-group). Clinical characteristics were similar between the two groups. There was a 96% reduction in total PET-days in 2018 (LTV-group compared with 2017 no-LTV group) (figure 1d).

**Conclusions:** 1) 80% of PET-days occurred before D100. 2) CMV-related readmissions cost an average $185,053 USD per patient. 3) Implementation of LTV prophylaxis resulted in a 96% reduction in total PET days by D100 post HCT.
Abstract 5032

Escherichia coli serotype O55:H9 as a new multidrug resistant hybrid pathotype producing Shiga toxin and carrying extra-intestinal virulence plasmid

Aurélie Cointe*, Patricia Mariani1, Bidet Philippe1, André Birgy1, Sophie Lefevre1, Sabine Delannoy1, Patrick Fach1, François-Xavier Weill2, Stephane Bonacorsi2

1Université de Paris, IAME/ Hôpital Robert-Debré, APHP Service de Microbiologie, Centre National de Référence Escherichia coli, PARIS, France, 2Institut Pasteur, Centre National de Référence des Escherichia coli, Shigella et Salmonella, Unité des Bactéries Pathogènes Entériques, PARIS, France, 3ANSES, Plateforme IdentyPath, Maisons-Alfort, France

Background: Enterohemorrhagic Escherichia coli (EHEC) are major food-borne pathogens responsible for gastrointestinal diseases which can be complicated by hemolytic uremic syndrome (HUS), first cause of acute renal failure in children. The multi-drug resistant O80 EHEC clone (ST301, fimH54) has recently emerged in Europe. It can be considered as a hybrid pathotype involved in HUS but also in extra-intestinal invasive infections potentially due to the presence of an additional virulence plasmid similar to pS88 involved in neonatal meningitis. In this study, we aim to know if such hybrid pathotype are restricted or not to O80 serogroup.

Materials/methods: To analyze the prevalence and the diversity of hybrid pathotype within the non-O80 EHEC serogroups of the French Reference National Center collection (2014-2018), we evaluated the presence of pS88 by multiplex PCR and characterized strains of interest by whole-genome sequencing (Illumina).

Results: We identified the serotype O55:H9 as another hybrid pathotype combining intestinal and extra-intestinal virulence factors characteristic of pS88. During the studied period, we identified 20 O55:H9 strains isolated from HUS cases (n=15), patients with diarrhea (n=3) or asymptomatic carriers among HUS entourage (n=2). No invasive infections were observed among these 20 cases. All strains carry Stx2 subtype (45% of Stx2d and 55% of Stx2a). A pS88-like plasmid is present in 95% of cases (n=19/20) harboring all characteristic genes except for one strain. Finally, the O55:H9 serotype appears to be phylogenetically closely related to O80 clonal group sharing the same ST301, fimH54 and eoe-. However, comparatively to O80 clone, all O55 strains carry the additional iron-uptake system yersiniabactin.

Conclusions: Our study reveals that hybrid pathotype strains combining intestinal and extra-intestinal virulence are not restricted to O80:H2 serotype but shared with O55:H9 serotype. The phylogenetic proximity between these two serotypes suggests a common origin followed by a change in somatic and flagellar loci. O80 and O55 EHEC serogroups, emerging clonal pathogens perfectly equipped to induce HUS and invasive infections, have to be strongly monitored worldwide.

Abstract 5035

**Klebsiella pneumoniae** type VI secretion system allows the implantation and survival of the pathogen within the intestinal microbiota

Thomas Merciecca¹, Laurence Nakusi¹, Stephanie Bornes², Céline Besnard², Etienne Rifa², Sebastien Theil², Christiane Forestier¹, Sylvie Miquel*¹

¹Université Clermont Auvergne, UMR CNRS 6023 LMGE, Clermont-Ferrand, France, ²Université Clermont Auvergne, INRA, VetAgro Sup, UMRF, Aurillac, France

Abstract third-party references: Supported by the Agence Nationale de la Recherche of the French government through the program “Investissements d'Avenir” [16-IDEX-0001 CAP 20-25], EMERGENCE 2018.

**Background:** Intestinal carriage is a significant risk factor for infections in intensive care unit with ~50% of *Klebsiella pneumoniae* infections resulting from patients’ contamination with their own microbiota. An anti-bacterial activity mediated by *K. pneumoniae* type six secretion system (T6SS) was recently highlighted in vitro. This system allows bacterial toxic effectors delivery in either prokaryotic or eukaryotic cells, after cell-to-cell contact. The aim of this study was to better characterize the role of T6SS in *K. pneumoniae* physiopathology and especially during the process of intestinal colonization.

**Materials/methods:** After an *in silico* analysis of T6SS organization clusters in *K. pneumoniae* CH1157 strain, the role of the cluster 1 was evaluated *in vivo* during the process of murine intestinal colonization using an isogenic mutant. The composition of the intestinal microbiota (16S rRNA high-throughput sequencing) of colonized mice was statistically analyzed (DESeq2, Metacoder, and MetagenomeSeq) to determine which bacterial phylia/genus became underrepresented in the presence of wild type versus mutant. In parallel, T6SS-1 expression has been assayed by RT-qPCR under different stress conditions (temperature, pH, bile salts, biofilm).

**Results:** *In silico* analyses reveal the existence of two T6SS-like genomic islands in the genome of *K. pneumoniae* CH1157 isolate, comprising putative elements of pathogenicity. *In vivo* experiments indicate that T6SS-1 promotes *K. pneumoniae* intestinal establishment in the lower part of the gastrointestinal tract. 16S rRNA high-throughput sequencing of the mice intestinal microbiota content confirm the establishment of an intestinal microbiota dysbiosis induces by the T6SS-1 of *K. pneumoniae*. Interestingly, the expression of this gene cluster is negatively correlated to sessile bacterial mode of life.

**Conclusions:** Altogether, these data will provide new insights into the physiopathological process of *K. pneumoniae* infection beginning by the T6SS-1 role into establishment of an intestinal microbiota dysbiosis, allowing the pathogen colonization. Pathogens’ SST6 impairment represents a new strategy for limiting the implantation of opportunistic pathogenic bacteria associated with high antibiotic resistance in part due to biofilm formation capacities.

Molecular epidemiology of invasive vancomycin-resistant Enterococcus faecium isolates
Laura Nürnberger*1, Dirk Schmidt1, Jörg Steinmann1,2, Peter-Michael Rath1
1University Hospital Essen, Institute of Medical Microbiology, Essen, Germany, 2Klinikum Nürnberg, Institute of Clinical Hygiene, Medical Microbiology and Infectiology, Nuremberg, Germany

Background: Vancomycin-resistant E. faecium (VREfm) have been listed as pathogens with high priority by the World Health Organization due to their high clinical relevance with decreasing therapeutic possibilities. Unfortunately, the VREfm prevalence has increased significantly in the last few years in Europe. In 2017, the percentage of VREfm has ranged between 10-25% in Germany. The resistance-type vanB has been detected more frequently than vanA in E. faecium since 2016.

Materials/methods: 128 invasive E. faecium isolates with vanB-type resistance were collected between 2011 and 2013 as well as between 2017 and 2018 in the University Hospital Essen and in 2018 in the Hospital Nuremberg, Germany. The isolates were characterized with the well-established microbiological methods multilocus sequence typing (MLST) and pulsed-field gel electrophoresis (PFGE).

Results: The 128 VREfm isolates were separated into 15 sequence types (ST) by MLST. All of these ST belong to the Clonal Complex 17, known to be responsible for nosocomial infections worldwide. While ST 117 was the most prevalent ST in Essen (48.2%) and in Nuremberg (36.2%), ST 192 was found solely in Essen between the years 2011 and 2012, accounting for 39.5% of the investigated isolates from Essen. ST 192 has been detected to be the second-most prevalent ST both in Essen and overall. In Nuremberg, the second leading ST was ST 78 with 23.4%. The PFGE divided the isolates included in this study into 68 PFGE types. Two local VREfm outbreaks in the cardiology 2011 and the perinatal center 2017 in the University Hospital in Essen could be confirmed. The PFGE also showed a broad genetic diversity between the VREfm isolates found in the two hospitals but also within different institutions and wards.

Conclusions: The results obtained by MLST confirmed the previously described allocation of ST in Germany. The variety of detected PFGE types might suggest a lower significance of intrahospital transmission of VREfm than expected. It rather indicates that a great part of VREfm-positive patients acquires VREfm and their corresponding PFGE type before hospitalization. More epidemiological studies are necessary to track and compare the intra- and interhospital spread and evolution of the genotypical populations.

The unexpected stability of Group B Streptococcus clones/serotypes colonising the genitourinary tract of healthy young women

Magdalena Ksiezarek, António Guimarães, Vanessa Martins, Joana Rocha, Svetlana Ugarcina Perovic, Filipa Grosso*, Luisa Maria Vieira Peixe

1Porto, UCIBIO/REQUIMTE, Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal

Background: Group B Streptococcus-GBS is often part of the normal gastrointestinal and genitourinary microbiota. However, it can cause serious neonatal infections, being the leading cause of neonatal mortality worldwide. Moreover, GBS has been increasingly associated with invasive disease in elderly and immunocompromised patients. GBS population structure has been explored mainly from infections and from pregnancy colonization, based on serotype (10 sialic acid-rich capsular polysaccharide variants -CPS) and MLST. In this study we characterized the population structure and stability of GBS population in the genital and urinary tract (UT) of young healthy women.

Materials/methods: Mid-stream urine (U) and vaginal swab (VS) samples were collected from 20 healthy non-pregnant women (age:25-37) with no clinical evidence of UT disorders, and no antibiotic treatment (previous month). Within 2.5 years interval, 10 women provided U and VS second samples. Samples underwent extended culturomic analysis (blood agar and supplemented chromogenic agar/different atmospheric conditions) with colonies identification by MALDI-TOF/MS and presumptive GBS isolates confirmed by dltS gene amplification. Further characterization included MLST and CPS-genotyping.

Results: GBS was detected in 50% of women (10/20). From these donors, only 5 presented GBS in both samples (U+VS), 2 presented only in VS and 3 only in U. A total of 197 GBS isolates were distributed among 6-STs/7-CPS-types: ST2/CPS-V; ST8/CPS-VI; ST10/CPS-II; ST10/CPS-V; ST19/CPS-II; ST28/CPS-II; ST31/CPS-IV. ST10 was the most frequent and presented higher CPS diversity. The hypervirulent strain ST17/CPS-III responsible for the majority of late-onset meningitis cases in neonates was not found; however, it is of note the presence of CPS-V and ST19/CPSIII that have been linked to invasive disease in non-pregnant adults. Interestingly, although GBS colonization fluctuations have been described, the paired samples from the same individuals (U/VS) presented the same clones at both sampling points.

Conclusions: Our study revealed an unexpected GBS-ST/serotype stability over time. It is of note the GBS detection only in U and not in VS in 3 donors, reflecting the need to rethink the current GBS screening procedures in pregnancy. GBS population structure and colonization patterns knowledge are essential to early identify GBS strains changes, and to guide the development of a potential serotype-dependent prophylaxis.

Respiratory syncytial virus and influenza virus infection in adult primary care patients: association of age with prevalence, diagnostic features and illness course

Robin Bruyndonckx1,2, Samuel Coenen134, Christopher Butler5, Theo Verheij6, Paul S. Little7, Niel Hens2,6, Philippe Beutels8, Margareta Ieven*1, Herman Goossens1

1University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Diseases Institute (VAXINFECTIO), University of Antwerp, Antwerp, Belgium
2Hasselt University, Interuniversity Institute for Biostatistics and statistical Bioinformatics [I-BIO-STAT], Data Science Institute [DSI], Hasselt, Belgium, University of Antwerp, Department of Epidemiology and Social Medicine [ESOC], Antwerp, Belgium, University of Antwerp, Department of Primary and Interdisciplinary Care [ELIZA], Antwerp, Belgium, Cardiff University, Institute for Primary Care and Public Health, Cardiff, United Kingdom, University Medical Centre Utrecht, Julius Centre for Health, Sciences and Primary Care, Utrecht, Netherlands, University of Southampton, Aldermaor Health Centre, Southampton, United Kingdom, University of Antwerp, Centre for Health Economic Research and Modelling Infectious Diseases [CHERMID], Vaccine & Infectious Disease Institute, Antwerp, Belgium

Background: Viral respiratory tract infections (RTIs) caused by respiratory syncytial virus (RSV) and influenza virus [influenza] are a major public health problem, especially during winter months. To better target new vaccines and treatments under development, we studied the association of age with prevalence, diagnostic features and illness course for RSV and influenza in adult primary care patients.

Materials/methods: Secondary analysis of observational data on the aetiology, diagnosis and prognosis in adults presenting to primary care with acute cough in 12 European countries [2007-2010] using regression analyses corrected for clustering of patients within countries. Age groups were 18-59 years, 60-74 years, and 75 years and older (75+).

Results: Nasopharyngeal swabs for 144 (4.8%) and 307 (10.2%) out of 3104 patients were polymerase chain reaction (PCR) positive for RSV and influenza, respectively. RSV-prevalence in patients 75+ (8.5%) was twice the prevalence in those under 60 years [4.2%]. Influenza prevalence was not associated with age. For both infections the diagnostic features were neither. For RSV, symptom duration was shorter in patients aged 18-59 years, while it was not associated with age for influenza. The odds of unresolved symptoms after 28 days was associated with age for both viruses, with patients aged 18-59 years at lower risk. Illness deterioration was associated with age for RSV, with patients 75+ at increased risk, but not for influenza (Table 1).

Table 1. Unresolved symptoms after 28 days in adult acute cough patients that tested positive for respiratory syncytial virus (RSV) or influenza virus in primary care.

OR: odds ratio; CI: [bootstrap-based] confidence interval; Numbers printed in bold indicate significance: models accounted for significant covariates (smoking status and presence of other viruses for RSV; gender, history of cardiac comorbidities, influenza vaccination, days coughing prior to consultation, presence of bacteria and presence of other viruses for influenza).

Conclusions: In adults presenting to primary care with acute cough, the diagnostic features of RSV or influenza infection are not associated with age. For RSV both the prevalence and illness course are significantly worse at higher age, for influenza only the illness course is.

Abstract 5043

**Dynamics of *Staphylococcus aureus* in the hospital environment and in patients: is the environment identified as a reservoir?**

Adriëne Stephanie Van Der Schoor*, Anne Voor In ‘t Holt1, Corné H. Klaassen1, Juliëtte A. Severin1, Diederik Gommers2, Marco J. Bruno3, Joke Hendriks4, Margreet C. Vos1

1Erasmus MC University Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands
2Erasmus MC University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands
3Erasmus MC University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands
4Erasmus MC University Medical Center, Department of Surgery, Rotterdam, Netherlands

**Background:** *Staphylococcus aureus* is a well-known colonizer of humans, but also an important pathogen. Little is known about the dynamics of methicillin sensitive *Staphylococcus aureus* (MSSA) in the hospital’s innate environment in relation to patient colonization. Therefore, we performed staphylococcal protein A (spa) typing of isolates from patients and the hospital environment to determine dynamics.

**Materials/methods:** Environmental samples were taken at 14 moments in a 16-month period from an old and a newly-constructed hospital. Each moment, 306 locations (e.g. nightstands) in 40 patient rooms were sampled. From January 2018 until August 2019, adult patients admitted to specific wards with an expected stay of ≥48 hours were asked to participate. Nasal swabs were obtained at admission and discharge. All samples were cultured for MSSA. Environmental samples were selected for spa typing when multiple locations in one room were positive at one moment or when one location was positive over time. Patient samples were selected for spa typing when patients were linked to MSSA-positive rooms.

**Results:** 116 out of 4082 (2.8%) environmental samples revealed MSSA. Admission and discharge cultures were taken from 690 patients. 121 patients (17.5%) were positive at admission and discharge, 64 (9.3%) were only MSSA positive at admission, and 16 (2.3%) acquired MSSA. Spa typing was performed on 74 environmental- and 36 patient samples. MSSA from multiple positive locations in one room at one moment had identical spa types. Samples from locations positive over time had different spa types. MSSA strains identified in patients were identical at admission and discharge, except for one patient. No transmissions from environment to patients or vice versa were observed. Most prevalent spa types from patients and environment were t026 (13.1%), 1012 (8.2%) and t091 (8.2%).

**Conclusions:** Based on the results, no transmission from patients to environment or vice versa is observed, although the change in MSSA type in one patient suggests this. However, since we were unable to sample all patients and rooms, possible transmissions may have been missed. Analysis of all environmental and patient isolates using additional typing methods with higher resolution is necessary for a further understanding of MSSA dynamics.

**Presenter email address:** a.vanderschoor@erasmusmc.nl
Evaluation of the Sepsis Flow Chip kit for the molecular diagnosis of bloodstream infections

Silvia Zannoli*, Gioviana Masciarelli, Maria Federica Pedna, Vittorio Sambri

1The Great Romagna Area Hub Laboratory, Pievesestina di Cesena, Italy

Background: Bloodstream infections (BSI) are a major cause of death with increasing incidence and severity. Blood cultures remain the gold standard for microbiological diagnosis but are time-consuming. Rapid diagnostic testing has proven useful in the improvement of patient outcomes by speeding up microbial identification and predicting antimicrobial susceptibility.

The purpose of this study is to evaluate the performance of the Sepsis Flow Chip Kit molecular assay (Vitro) for the detection of 36 bacterial species, Candida species and 20 antibiotic resistance markers.

Materials/methods: A total of 166 positive blood culture samples were analysed with the Sepsis Flow Chip Kit assay. Time-to-result is 4 hours for a 12-sample batch. The test performance was compared to the culture-based workflow currently in place, consisting of identification (MALDI-TOF MS - bioMérieux) and antimicrobial susceptibility testing (Vitek 2 - bioMérieux).

Results: Out of 166 tested samples, 3 were excluded for lack of amplification of the external control, due to the presence of inhibitors, and 7 as positive for bacteria not included in the assay panel.

Out of 156 results suitable for comparison, 141 showed complete agreement with the reference algorithm (91%). In 2 polymicrobial samples, the molecular test yielded a concordant result with an added identification, while in 3 more polymicrobials it was in agreement with the standard diagnostic workflow for one target, but missed the second.

In 9 cases (6%), the Vitro assay tested negative with a positive culture result. Finally, Proteus mirabilis was misidentified by the molecular test as Morganella morganii within a polymicrobial sample. This was due to an incorrect software interpretation of amplified targets belonging to a second pathogen (Klebsiella pneumoniae).

Conclusions: The Sepsis Flow Chip Kit assay showed an overall ease of use and a rather short turnaround time, which would prove useful in a time-sensitive setting such as BSI diagnosis. The results obtained are generally in agreement with those of the culture-based algorithm used as a reference workflow; however, the discrepancies that emerged within the study need to be further investigated as to accurately gauge the system’s sensitivity, in light of a potential use in a diagnostic setting.

Mutations in PBP3 conferring β-lactams resistance in Haemophilus parainfluenzae

Daniel Pablo Marcos*, 1, Leticia Armendariz 1, Maria Siller Ruiz 1, Jesus Aguero 1, Jorge Calvo-Montes 1

1 Santander, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Haemophilus parainfluenzae is an opportunistic pathogen of upper respiratory and genitourinary tract. Due to widespread and frequent use of β-lactams, resistance to these antimicrobials has been developed. One of the main mechanisms of β-lactams resistance consists on amino-acid substitutions in PBP3 encoded by ftsI gene. The aim of this study was to determine mutations in PBP3 in H. parainfluenzae which confer resistance to β-lactams by sequencing ftsI gene.

Materials/methods: 17 clinical isolates of H. parainfluenzae recovered at Hospital Universitario Marqués de Valdecilla during 2012-2019 were studied. Antimicrobial susceptibility was performed using gradient strips (Etest®) and according to EUCAST both disk diffusion guidelines and breakpoints for H. influenzae. FtsI gene was amplified by PCR using the primers described by Tristam et al (1). PCR product was sequenced and aligned with nucleotide BLAST between our isolates and H. parainfluenzae T31 (GenBank code Q312002.1). Amino-acid substitutions were obtained with Sequencher software.

Results: The most common substitutions in PBP3 were N526K/H/S and V511A, and were associated with resistance to AMC and FUR. All cefotaxime-resistant isolates presented mutations in S385T+I442F (n=11, ertapenem susceptible) or T443A+T322I (n=2, ertapenem-resistant). The single meropenem-resistant isolate showed additional mutation in D551Y, not present in any of the other isolates.

Previously described substitutions K276N, A307N and V329I, although of unclear significance, were also appeared in 5 cefotaxime resistant isolates.

Conclusions: The most prevalent mutations [N526K/H/S and V511A] described in H. influenzae conferring resistance to β-lactams, were also detected in our H. parainfluenzae isolates.

PB3 mutations T443A, T322I and D551Y were detected in carbapenem resistant isolates, but additional site-directed mutagenesis studies are needed to confirm this association.

**Abstract 5047**

**The incremental clinical value of metagenomic next-generation sequencing when applied to microbiological diagnosis of skin and soft tissue infections**

Qingqing Wang*1, Qing Miao1, Jue Pan1, Wenting Jin1, Yuyan MA1, Yao Zhang1, Yi Su1, Li Na1, Bijie Hu1

1Zhongshan Hospital of Fudan University, Shanghai, China

**Background:** Metagenomic next generation sequencing (mNGS) with its comprehensiveness has been widely applied in microbiological diagnosis. Etiological diagnosis is of paramount clinical importance in skin and soft tissue infections (SSTIs) patients. Meanwhile, the clinical application of mNGS in SSTIs is little known.

**Materials/methods:** From April 1st 2017 to October 30th 2019, 100 SSTIs cases were enrolled. The main classification was pyomyositis (n=32), followed by subcutaneous abscess (n=30) and impetigo (n=16). The positive rates of pathogens detected by mNGS and culture were compared by analyzing the tissues, pus, swabs and/or interstitial fluids of infected parts. The modification of antibiotics treatment strategy due to mNGS were also assessed.

**Results:** The sensitivity of mNGS for detecting pathogens in SSTIs cases was superior to that of culture (71.0% vs 36.0%; p=0.041). mNGS was able to identified a significantly higher rates of virus (14.0% vs 0.0%; p<0.01), anaerobe (11.0% vs 3.0%; p<0.01), mycobacterium tuberculosis (17.0% vs 11.0%; p<0.01) and non-tuberculous mycobacterium (6.0% vs 3.0%; p<0.01) compared with culture. Notably, some rare pathogens were detected by mNGS such as vibrio vulnificus and bartonella henselae. Importantly, proportion of multi-pathogens infections of SSTIs in mNGS was superior to that of culture (13.0% vs 7%; p=0.045). The rate of targeted antibiotics treatment was significantly higher in mNGS-positive cases than that in mNGS-negative cases (33.0% vs 2.0%; p<0.01). In the culture-negative and mNGS-positive cases, the improvement rate was higher than that in mNGS-negative cases, while there was no significant difference (25.0% vs 5.0%; p=0.281).

**Conclusions:** mNGS is a promising tool of etiological diagnosis for SSTIs, particularly in identifying virus, anaerobes, mycobacteria and multi-pathogens infection. Application of mNGS testing to clinical practice is able to change antibiotics treatment strategies and partly benefit clinical outcomes.

Abstract 5051

**Sensitivity of the pneumococcal urinary antigen ImmuView in proven or probable pneumococcal pneumonia**

Guillem López De Egea*, Aida González Díaz1, Mª Ángeles Domínguez Luzon1, Carmen Ardanuy Tisaire1

1Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain

**Background:** ImmuView® is an immunochromatographic test which detects pneumococcal and Legionella antigens in urine samples. The aim of this study was to evaluate the sensitivity of pneumococcal urinary antigen ImmuView® to detect probable or proven pneumococcal pneumonia. Furthermore, to analyze its sensitivity regarding the pneumococcal serotypes.

**Materials/methods:** We collected urine samples from patients with probable pneumococcal pneumonia (symptoms of infection plus a sputum or blood culture with *Streptococcus pneumoniae*). The samples were prospectively tested for pneumococcal urinary antigen with Binax® and preserved frozen. After thawed, samples were tested with ImmuView®. Clinical isolates of *S. pneumoniae* were serotyped using ImmuLex PNEUMOTEST KIT® and/or Quellung reaction. The antibiotic susceptibility was tested by microdilution following EUCAST recommendations.

**Results:** A total of 53 probable pneumococcal pneumonia episodes were detected over the study period (Jul 2018 - Jun 2019). Of them, 33 had blood cultures and 20 respiratory specimens with *S. pneumoniae*. The most frequent serotypes were 3 (11.3%) and 8 (11.3%). The antibiotic susceptibility rates were penicillin 79.2% (MIC≤0.06 mg/L), levofloxacin 98,2% and erythromycin 84.9%. The 1.9% of the isolates had a penicillin MIC >2mg/L. The Binax® urinary antigen detection was positive in 40 of 53 probable pneumococcal pneumonia episodes. While the ImmuView® test was positive in 37 out these 53 urine samples after thawing (p=0.4). No Legionella antigen was co-detected together with pneumococcal. No differences in sensitivity were found regarding serotypes.

**Conclusions:** The ImmuView® had a good sensitivity to detect pneumococcal antigen in urine samples of patients with proven or probable pneumococcal pneumonia even in frozen samples.

**Presenter email address:** glopezdeegea@bellvitgehospital.cat
**Effectiveness of single-dose of doxycycline for the prevention of tick-borne relapsing fever**

Yoav Binenbaum¹, Ronen Ben-Ami², Gad Baneth³, David Shasha³, Boaz Langford⁴, Yoav Negev⁴, Luba TAU¹, Yael Paran⁵

¹Dana Dwek Children’s Hospital, Tel Aviv Sourasky Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Israel, Tel Aviv, Israel, ²Infectious Diseases Unit, Tel Aviv Sourasky Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, ³Koret School of Veterinary Medicine, The Hebrew University, Jerusalem, Israel, ⁴Israel Cave Research Center, Institute of Earth Sciences, The Hebrew University, Jerusalem, Israel

**Background:** Tick-Borne Relapsing Fever (TBRF) can be effectively prevented by post exposure prophylaxis (PEP) with doxycycline. However, unlike PEP for Lyme disease, the traditional regimen for the prevention of TBRF consists of 5 days of treatment.

**Materials/methods:** In this observational study, data were collected from 80 spelunkers regarding their self-administered PEP habits following exposure to cave-ticks. Data were collected using a 47-item questionnaire published on social networks and on the website of the Israel Cave Research Center (February 2016 to July 2019). TBRF occurrence was compared in subjects taking a single dose PEP, defined as one dose of 100 mg doxycycline within 72 hours of tick exposure, to subjects not using PEP.

**Results:** One hundred thirty-five tick-exposure events were recorded. PEP was administered following 89 (66%) of the 135 reported events, and in 84% of these only one dose of doxycycline was used. TBRF occurred in 43% of events that were not followed by PEP administration. PEP consisting of a single dose of 100 mg Doxycycline provided 100% efficacy in preventing TBRF, p<0.0001 for between group difference of TBRF occurrence. Thirty four exposure cases took place in Borrelia persica positive caves, defined as caves where confirmed TBRF cases were acquired. Of 16 persons not taking PEP, nine TBRF cases were reported, representing an attack rate of 56%. None of the 16 individuals (57%) receiving PEP with Doxycycline were infected (13 out of 16 took 1 dose of doxycycline, for whom p<0.0002 for between group difference of TBRF occurrence).

**Conclusions:** This study, which mapped spelunkers self-administered PEP regimens after exposure to cave-ticks, demonstrated that a single dose of 100 mg doxycycline taken within 72 hours of exposure is comparable to a 5-day course, and is 100% effective for the prevention of TBRF.

**Figure 1.** Exposure events, PEP regimen and TBRF occurrence. Figure 1. 1a. Entire study population. 2a. Exposure in Borrelia positive caves (caves in which a person has been reported of acquiring TBRF).

Evaluation of the rapid ResaPolymyxin Acinetobacter/Pseudomonas NP test for rapid screening of colistin resistance in non-lactose fermenters

Hyun-Sul Jung*, Johann Pitout1,2, Barney Mitton1,3, Kathy-Anne Strydom1,4, Chanel Kingsburgh4, Nontombi Mbelle1,3, Marthie M. Ehlers1,3, Marleen Kock1,3

1Department of Medical Microbiology, Faculty of Health Sciences, University of Pretoria, Pretoria, South Africa, 2Division of Microbiology, Alberta Public Laboratories, Cumming School of Medicine, University of Calgary, Calgary, Canada, 3Department of Medical Microbiology, Tshwane Academic Division, National Health Laboratory Service (NHLS), Pretoria, South Africa, 4Ampath Laboratories, Pretoria, South Africa

Background: Pseudomonas aeruginosa and Acinetobacter baumannii form part of the ESKAPE pathogens that are of global concern due to their ability to acquire multidrug and pandrug resistance. As colistin is used as one of the last resort antibiotics, rapid screening of colistin susceptibility is crucial for infection control and antibiotic stewardship. Recently, the Rapid ResaPolymyxin Acinetobacter/Pseudomonas NP (RPNP) test, a colorimetric assay based on the bacterial metabolism that reduces resazurin (blue) to resorufin (pink), was developed for non-fermenting Gram-negative bacteria. The aim of the study was to evaluate the performance of the RPNP test as compared to the broth microdilution (BMD) assay using a collection of clinical carbapenem-susceptible and -resistant P. aeruginosa and A. baumannii isolates.

Materials/methods: A total of 126 P. aeruginosa (106 colistin-susceptible and 20 colistin-resistant according to BMD) and 52 A. baumannii isolates (31 colistin-susceptible and 21 colistin-resistant according to BMD) with colistin minimum inhibitory concentrations (MICs) in the range of 0.125 to >64 mg·L⁻¹ were included in the study. The reference method was colistin BMD performed and interpreted according to the EUCAST/CLSI joint guidelines. Isolates were considered susceptible when colistin MICs were ≤2 mg·L⁻¹ and resistant when colistin MICs were >2 mg·L⁻¹. The RPNP test was performed and interpreted as previously described. Isolates were considered colistin-susceptible if a blue colour was observed and resistant if a purple or pink colour was observed.

Results: The categorical agreement between the reference method and the RPNP test was 69% for P. aeruginosa and 94% for A. baumannii. Very major error (false susceptibility) was observed in 45% (9/20) of P. aeruginosa isolates and 10% (2/21) of A. baumannii isolates. Major error (false resistance) was more commonly observed in P. aeruginosa isolates (28%: 30/106) than in A. baumannii isolates (3%; 1/31). The sensitivity and specificity of the RPNP test was poor in P. aeruginosa isolates (55% and 72%) but were in an acceptable range for A. baumannii isolates (90% and 97%).

Conclusions: The RPNP test is a rapid, inexpensive screening test that performs better for A. baumannii, but not for P. aeruginosa.

Dual RNase and β-lactamase activity of a single enzyme encoded in most Archaea

Seydina M. Diene1, Lucile Pinault1, Nicholas Armstrong2, Said Azza1, Vivek Keshri1, Khelaifia Saber1, Eric Chabrière1, Gustavo Caetano-Anólles2, Jean-Marc Rolain1, Pierre Pontarotti1, Didier Raoult1,3

1Aix-Marseille University, MEPhI, IHU-Méditerranée Infection, Marseille, France, 2University of Illinois at Urbana-Champaign, Evolutionary Bioinformatics Laboratory, Department of Crop Sciences, Urbana, United States, 3IHU-Méditerranée Infection, Marseille, France

Background: β-lactamases enzymes have been so far identified thanks to their hydrolyzing activities on β-lactam antibiotic family. However, annotation of genomes of multiple living species showed that homologous β-lactamase sequences were present in most living organisms, including those for which there are no known β-lactam targets. This the case in Human but also in Archaea in which two groups of β-lactamases are present in the majority of Archaea which are not, by nature, susceptible to β-lactams, in whom alternative role of these enzymes may be suspected, such as nuclease, ribonuclease, or glyoxalase thanks to the shared motif “HxHxDH” with class B metallo-β-lactamase (MBL) enzymes. Here, we express two archaeal β-lactamases and investigate their different activities.

Materials/methods: The Archaea β-lactamases were identified by blastP analysis using as targets inferred ancestor sequences for bacterial β-lactamases. Selected sequences were synthetized by GenScript (Piscataway, USA) and optimized for protein expression in Escherichia coli in the pET24a(+) expression vector. Purified enzymes were tested for β-lactamase activity on nitrocefin and β-lactams using the Cefinase paper disc test and Liquid Chromatography-Mass Spectrometry (LC-MS). The nuclease activity was evaluated on synthetized single and double-stranded DNA whereas the ribonuclease activity was evaluated using the RNaseAlert QC System kit (Fisher Scientific, France) and on extracted bacterial RNA. Glyoxalase II activity was determined using the Glyoxalase II Activity kit from BioVision (Milpitas, USA).

Results: Class B and C β-lactamases were identified in most Archaeal genomes. Class B sequences appeared highly conserved in several classes of archaea and have been transferred into the single bacterial family, i.e. Flavobacteriaceae (especially Elizabethkingia). The expressed class B β-lactamase from Methanosarcina barkeri digests nitrocefin and penicillin G. While a weak glyoxalase activity was detected, a significant ribonuclease activity was demonstrated. The expressed class C-like β-lactamase, also from Methanosarcina sp., shows β-lactamase activity and was more closely related to DD-peptidase enzymes.

Conclusions: Our findings highlight the requalification needness of annotated enzymes as β-lactamases, either by annotating them a more neutral name or by giving them name containing at least β-lactamase-nuclease, so as not to neglect an aspect probably essential to the life of this group of enzymes.

Infectious disease consultation reduces time to appropriate antimicrobial treatment in Gram-negative bacteraemia: data from an area of high prevalence of antibiotic resistance

Valentina Da Prat1, Laura Galli1, Matteo Moro1, Paola Cichero1, Barbara Castiglioni2, Chiara Oltolini2, Chiara Tassan Din2, Andrea Poli2, Cristina Össi2, Andrea Andolina1, Alberto Ambrosio2, Adriano Lazzarin2, Antonella Castagna1,2, Paolo Scarpellini2, Marco Ripa1,2

1Università Vita-Salute San Raffaele, Milan, Italy, 2IRCCS Ospedale San Raffaele, Milan, Italy

Background: Administration of appropriate antimicrobial treatment can be challenging in areas of high prevalence of antibiotic resistance. This study evaluated the impact of infectious disease consultation (IDC) on time to and risk of appropriate antimicrobial treatment (AAT) for Gram-negative bacteraemia (GNB).

Materials/methods: Retrospective observational study on patients with GNB hospitalized at San Raffaele Hospital (Milan, Italy) between January-December 2017. Patients' demographics, microbiological data and all therapeutic prescriptions for every GNB were collected from clinical records. Only the first episode of GNB was evaluated. IDC was requested at treating physician's discretion. Resistance was defined as non-susceptibility to third-generation cephalosporins, piperacillin-tazobactam and/or carbapenems. Therapy was deemed AAT if the antibiotic had the narrowest spectrum considering infection site, polymicrobial aetiology, allergies and comorbidities. In case of multiple AAT, time to first AAT was calculated. We identified a group of patients with interventional IDC (I-IDC) which included: 1) patients with the first AAT suggested by IDC; 2) patients without AAT with the last therapeutic modification suggested by IDC. Results were described as percentage, median (interquartile range). Time to AAT was evaluated by Kaplan-Meier curves. Factors associated with risk of AAT were assessed by Cox proportional-hazard models; [adjusted] hazard ratios ([a]HR) with 95% confidence intervals (95%CI) were reported.

Results: 471 patients; age 69.8 (61.0-77.4), 63% males; hospital units: Emergency Department (23.6%), Surgery (30.6%), Medicine (31.4%), Intensive Care Unit (ICU, 11.7%). GNB sustained by resistant bacteria in 38.2% of cases. Empiric therapy prescribed during IDC in 12.7% of patients.

Overall, 29.9% of patients received an I-IDC. In subjects without empiric AAT (n=263), patients with and without I-IDC had a median time to AAT of 2 days (95%CI=2-3) vs 7 (95%CI=3-10), respectively (p<0.0001; Figure). At multivariate analysis, I-IDC was associated with AAT in this subset (aHR=2.318 [1.643-3.270]) and confirmed in the whole cohort (aHR=1.339 [1.052-1.705]), after adjusting for age, sex, admission ward, previous surgery, Charlson/Pitt score, infection site, time to bacteremia, previous isolation of multidrug-resistant organisms, previous ICU stay, resistant phenotype, previous IDC.

Conclusions: In an area of high prevalence of antibiotic resistance, infectious disease consultation was associated with earlier prescription of appropriate therapy in Gram-negative bacteremia.
Abstract 5057

Utilising long-read shotgun sequencing to study the lower respiratory tract microbiome from endotracheal aspirate samples

Juan Pablo Rodriguez Ruiz*, Minh Nguyen Ngoc1, Basil Britto Xavier1, Jasmine Coppens2, Christine Lammens1, Veerle Matheeussen2, Herman Goossens1,2, Surbhi Malhotra-Kumar1

1Laboratory of Medical Microbiology, University of Antwerp, Antwerp, Belgium, 2Department of Clinical biology, Antwerp University Hospital, Edegem, Belgium

Background: Long-read sequencing helps to determine high-resolution species composition and the genetic context of resistance genes, although samples such as endotracheal aspirates (ETA) are enriched in host DNA. Here, we evaluate a saponin treatment on ETA samples to reduce host DNA in order to increase the number of microbial reads to answer clinically relevant questions.

Materials/methods: A set of ETA samples (n=4) were obtained from patients (n=4) in UZA (Antwerp University Hospital). The samples were liquefied with lysomucil (acetylcysteine) and subjected to metagenomic DNA extraction using ZymoBiomics DNA/RNA Miniprep Kit (Zymo Research, USA) with and without a saponin (Thermo Fisher, USA) treatment to remove host DNA from the sample. Singleplex and multiplex library preparation was performed using SMRTBell Template Prep Kit 1.0 (Pacific Biosciences, USA) and sequencing in Sequel with SMRTCell v3 (Pacific Biosciences, USA). The same samples were sequenced using short-read shotgun sequencing (MiSeq, Illumina, USA). Host reads were removed by reference mapping using CLC Genomics workbench (Qiagen, Germany). Remaining long-read sequences were analysed using WIMP (What is In My Pot) workflow and assembled with MetaFlye. Similarly, short-read sequences were assembled using metaSPAdes. All assemblies were analysed using BacPipe v.1.2.6 for annotation and resistance gene detection (Figure 1A).

Results: Multiplexing of clinical samples for shotgun metagenomics on Sequel platform was successfully validated and shown to be more cost-effective [1,066€/sample:singleplex vs 561€/sample: multiplex], producing enough coverage for all samples (Figure 1B). Saponin treatment showed 30-99% of host DNA removal in treated samples, without affecting the bacterial DNA, but significantly affecting fungal DNA (Figure 1C). The results entirely correlated with the phenotypic data (species detection, susceptibility profile). Additionally, long-read sequencing was capable of identifying the complete genetic characterisation of the beta-lactamase gene and detection of integrative conjugative elements (ICE), which was incomplete in short-read sequencing (Figure 1D).

Conclusions: We show the importance of saponin treatment to remove host DNA in ETA samples with low bacterial content and the feasibility and cost-effectiveness of multiplexing for long-read shotgun sequencing, deriving in enough coverage for taxonomaical classification and resistance genes detection.

Abstract 5059

**Method comparison: Abbott Alinity m STI (CT, NG, MG, TV) vs Hologic Aptima CT/NG & Aptima MG**

Martin Obermeier*, Stefan Breuer1, Jens Dhein2, Robert Ehret1

1MVZ Medizinisches Infektiologiezentrum Berlin, Berlin, Germany, 2Abbott Molecular, Abbott GmbH & Co. KG, Wiesbaden, Germany

**Background:** High rates of sexual transmitted infections (STI) reported in the MSM population lead to a rise in awareness and in testing. The implementation of pre-exposure prophylaxis in the MSM community to prevent HIV-infections includes regularly STI screening tests leading to higher demands on STI tests. We here compare the results of two random access systems, the newly launched Abbott Alinity m STI and the established Hologic Aptima CT/NG & Aptima MG assays.

**Materials/methods:** 257 Left-over routine samples from requests for Neisseria gonorrhoeae, [NG] Chlamydia trachomatis [CT] and Mycoplasma genitalium [MG] or combinations thereof were analysed with the Aptima assay and retested on the Abbott Alinity m STI. 105 swabs (different locations: pharyngeal, anal and urethral) collected in Aptima swab specimen collection tube, 148 urine in urine specimen collection tubes and 4 urine/swab mixes were tested. Trichomonas vaginalis [TV] results were only available with the Alinity m STI assay.

**Results:** An overall concordance of 98.1% between the Aptima and the Alinity m assays could be reached when equivocal results of the Aptima assay (N=2) were defined as positive. Of 162 tested samples we observed 7 discordant results for MG which were positively detected only in the Aptima assay. NG testing revealed four discordant results with 3 positive detections only in the Alinity m assay and one only detectable in the Aptima assay. 3 discordant results for CT divide into 2 samples only detectable in the Alinity m assay vs. one only in the Aptima assay.

**Conclusions:** The Alinity m STI assay showed high concordance with Aptima CT/NG & Aptima MG assays. With random access, the ability to continuously load samples and detection of 4 STIs simultaneously the Alinity m STI is an excellent alternative to three Aptima STI assays. In addition the Alinity m STI includes a cellular control to assess the quality of the material.

Abstract 5064

Activity of peracetic acid against MDR Enterococcus faecium and non-typhoidal Salmonella from diverse epidemiological and genetic backgrounds

Andreia Rebelo*1,2, Barbara Duarte1, Ana Raquel Freitas1, Ana Callejón3, Luisa Maria Vieira Peixe1, Carla Novais1, Patricia Antunes1,4

1Universidade do Porto, UCiBiO/REQUIMTE. Laboratório de Microbiologia, Faculdade de Farmácia, Porto, Portugal, 2Instituto Politécnico do Porto, Escola Superior de Saúde, Porto, Portugal, 3Universidad de Granada, Facultad de Farmacia, Granada, Spain, 4Universidade do Porto, Faculdade de Ciências da Nutrição e Alimentação, Porto, Portugal

Background: Multidrug-resistant (MDR) bacteria represent one of the greatest challenges worldwide, with antiseptic/disinfectants assuming an increasing relevance to prevent MDR-bacteria transmission in food-chain and hospital contexts. Foodborne pathogenic non-typhoidal Salmonella-NTS from emergent serotypes/clones and particular hospital-adapted clonal lineages of Enterococcus faecium-Efm cause thousands of human infections worldwide. Peracetic acid (PAA) is widely used in food-chain (20-3000mg/mL) and healthcare environments (150-2000mg/mL) to disinfect surfaces/hands, but its activity has not been tested in bacteria from diverse epidemiological and genetic backgrounds. Here we evaluated PAA tolerance of MDR Efm and NTS from diverse origins and clones/serotypes.

Materials/methods: We included 74-Efm and 60-NTS recovered from humans (n=54), food-animal production setting/foods (n=75), and environment (n=5) [1997-2018; 6-countries]. Efm strains included were from hospital [21-clade A1] and community [37-clade A2; 9-clade B] associated clonal lineages and among NTS, 17-serotypes were considered, including the most frequent 5. Typhimurium, 17. 4,[5],12:i:- and 3. Enteritidis. Most of the isolates were MDR [Efm 76%-n=56/74; NTS 73%-n=44/60]. The MICPAA was performed by broth-microdilution (ISO20776-1:2006; 37ºC/24h) followed by MBCPAA (NCCLS:1999; 37ºC/48h) (minimum 2 replicas/isolate), using a concentration range of 40-170mg/L. Induction assays were performed in 6-NTS and 6-Efm (diverse MIC/MBCPAA; genetic backgrounds), exposing bacteria (log-phase: 3-4h) to sub-inhibitory PAA concentrations (up to 10/100 times less the MICPAA) followed by MIC/MBC assay.

Results: Efm presented a MICPAA=70-120mg/L and MBCPAA=100-170mg/L [MIC90=110mg/L; MBC90=170mg/L]. NTS presented a MICPAA=50-70mg/L and MBCPAA=60-100mg/L [MIC90=70mg/L; MBC90=90mg/L]. No differences in MIC/MBCPAA were observed among isolates from diverse sources or MDR/non-MDR bacteria. Efm from clade A1 (62%-n=13/21; 70%-n=9/13 vancomycin-resistant ) showed a MBC equal or higher to the minimal concentrations recommended in ready-to-use products for hand disinfection in hospitals ([150mg/L], and all NTS a MBC higher to the minimal concentrations recommended in food/beverage industry (20mg/L). The induction with PAA did not affected the MIC/MBC in any isolates tested.

Conclusions: We unveil that MDR bacteria with clinical relevance survive to PAA concentrations used in different contexts, including most frequent NTS serotypes and Efm from hospital-adapted clonal lineages. Contrasting with other biocides, exposure to sub-inhibitory PAA concentrations seems not to have an impact on tolerance development in the few strains studied, deserving further studies.

Abstract 5068

**HCV resistance patterns in a large international cohort of DAA-naïve and -experienced patients with GT3a infection**

Slim Fourati, Francesca Ceccherini-Silberstein, Anita Howe, Vella Chiara Di Maio, Adolfo De Salazar, Stephanie Popping, Enoch Tay, Chathuraka Rodrigo, Evan B. Cunningham, Midori Kjellin, Perpetua Gomes, Enoch Taylor, Chathuraka Rodrigo, Evan B. Cunningham, Jochen Kaiser, Vladimir Chulanov, Joaquín Cabezas, Juan Carlos Alados Arboledas, Mark Douglas, Federico García García, Richard Harrigan, Jean-Michel Pawlotsky

**Background:** HCV genotype 3a (GT3a) is highly prevalent worldwide. GT3a is recognized as one of the most difficult-to-cure HCV genotypes. The international SHARED consortium investigated the prevalence and characteristics of resistance patterns in GT3a-infected DAA-naïve and -experienced patients from various regions.

**Materials/methods:** Sequence and clinical data from 735 chronically infected HCV GT3a patients were collected from a database of 2656 HCV-infected patients from 17 countries. Resistance Associated substitutions (RASs) were defined according to 2018 EASL HCV guidelines.

**Results:** In DAA-naïve patients (n = 351), no NS5B RASs were detected, whereas NS3 RASs were found in 3% (e.g. Q80K/R, Q168R) and NS5A RASs in 22% of patients (with A30K and Y93H, at 5% and 7% respectively). In DAA-experienced patients (n = 384) failing NS5A inhibitor-based therapy (SOF/DCV+/-RBV, 65.1%; SOF/LDV+/-RBV, 13.3%; SOF/VEL+/-RBV, 10.7%; SOF/VEL/VOX+/-RBV, 2.3%; G/P, 2.3% and others 6.2%), 78.8% of patients harbored NS5A RASs at failure. NS5A Y93N/H was the most prevalent RAS (66.2%), present after failure of all NS5-inhibitor containing regimen except ledipasvir, followed by NS5A A30K/S (17%). NS5A A30K was more frequently present after SOF/VEL/VOX or G/P failure (33% and 44% respectively) than after SOF/DCV or SOF/VEL failures. The combination of NS5A A30K and Y93H was rarely detected, except in patients failing SOF/VEL/VOX or G/P. In contrast, the majority of NS5A A30S was frequently associated with Y93H after DCV and VEL containing regimen failures. In addition to NS5A RASs, NS3 RASs including Y56H, Q80K, A156G, and Q168R were present in 62.5% of patients failing G/P (≥2 RASs, 50%). The frequency of NS5B S282C/T was low (1.2%) in patients failing SOF-containing regimens. No NS5B polymorphisms (including at positions 150 and 206) were associated with SOF-containing regimen failures.

**Conclusions:** In this large international cohort of GT-3a infected patients, the vast majority of patients who failed to achieve SVR harbored resistant HCV variants carrying one or two NSSA RASs, the most frequent being Y93H. The frequency of the co-occurrence of Y93H with another RAS at position 30 (A30S, A30K) depended on the treatment regimen received (first versus last-generations DAA). Multiple NS3 and NSSA RASs can challenge retreatment with last-generation NSSA inhibitors.

**Presenter email address:** slim.fourati@aphp.fr
Detection of Borrelia burgdorferi cell-free DNA in human plasma samples for improved diagnosis of early Lyme borreliosis

John Branda*1, Jacob Lemieux1, Lily Blair2, Asim Ahmed3, David Hong3, Sivan Bercovici2, Timothy Blauwkamp2, Desiree Hollemon2, Carine Ho1, Klemen Strle4, Nitin Damle1, Timothy Lepore6, Nira Pollock7

1Massachusetts General Hospital, Harvard Medical School, Boston, United States, 2Karius Inc., Redwood City, CA, United States, 3Vir Biotechnology, Inc., Mountain View, CA, United States, 4Wadsworth Institute, Albany, NY, United States, 5South County Internal Medicine, Inc., Wakefield, RI, United States, 6Nantucket Cottage Hospital, Nantucket, MA, United States, 7Boston Children's Hospital, Harvard Medical School, Boston, MA, United States

Background: Erythema migrans (EM), the skin rash of early Lyme borreliosis (LB), is a non-specific physical finding unless a classical targetoid lesion with central clearing is identified. In 80-90% of EM skin lesions, the rash is not classical, and a rash is absent entirely in approximately 20% of early LB cases. Confirmation of suspected cases is challenging, as serology and blood PCR are insensitive in early LB. Here, we demonstrate that detection of Borrelia burgdorferi (B. b.) cell-free DNA (cfDNA) in plasma can improve diagnosis of early LB.

Materials/methods: B. b. cfDNA detection in plasma samples was compared with serology and blood PCR in 40 patients with physician-diagnosed EM, 28 of whom were confirmed to have LB by skin biopsy Borrelia culture (N=18), seroconversion (N=2) or both (N=8). These 28 individuals were classified as having “laboratory-confirmed” EM.

Results: B. b. cfDNA was detected in 18/28 patients (64%) with laboratory-confirmed EM. In comparison, the sensitivity of acute-phase serology using modified two-tiered testing (MTTT), in which two different enzyme immunoassays are applied without the use of immunoblots, was 50% (P=0.45). Sensitivity of blood PCR was 7% (P=0.0002). Combining B. b. cfDNA detection and MTTT increased diagnostic sensitivity to 86%, significantly higher than either approach alone (P≤0.04). B. b. cfDNA sequences matched precisely with strain-specific sequence generated from the same individual’s cultured B. b. isolate. B. b. cfDNA was not detected in plasma from 684 asymptomatic ambulatory individuals. Among 3000 hospitalized patients tested as part of clinical care, B. b. cfDNA was detected in only two individuals, both of whom had clinical presentations consistent with LB.

Conclusions: This study demonstrates the potential clinical utility of B. b. cfDNA detection in the diagnosis of early LB. The combination of B. b. cfDNA and acute-phase MTTT improves sensitivity compared with either method alone.

Abstract 5075

**Characterisation of resistance-increasing determinants of OXA-48-bearing clinical isolates of Klebsiella pneumoniae**

Lisa-Marie Höfken*1, Martina Cremanns1, Sören G. Gatermann1, Niels Pfennigwerth1

1Ruhr-Universität Bochum, Bochum, Germany

**Background:** Nosocomial infections with multidrug-resistant Gram-negative pathogens are an emerging problem in healthcare systems worldwide. Some isolates of *Klebsiella pneumoniae*, that carry an OXA-48 carbapenemase, are carbapenemase resistant and some are not. Here we investigated an additional mutation in the *ompK36* gene, which encodes for a channel protein embedded in the outer membrane, that may increase the resistance of such isolates.

**Materials/methods:** A carbapenem susceptible *K. pneumoniae* with an OXA-48 carbapenemase was placed under selective pressure with meropenem. A mutant could be selected in vitro, which in addition to production of OXA-48 had an amino acid deletion in OmpK36 at positions V320 and G321. To investigate the effect of this deletion, this mutation was introduced into a clinical OXA-48-producing carbapenem-susceptible isolate of *K. pneumoniae* using the λ-Red recombination system. MICs of the wildtype and the porin mutant were determined using broth microdilution and interpreted according to EUCAST. The effect of the porin mutation on bacterial fitness was analysed by growth experiments.

**Results:** Resistance testing of the mutant showed increased MICs of several cephalosporins, mecillinam and carbapenems. In growth experiments, a fitness loss of the OmpK36 mutant compared to the wild type was also observed. The mutated porin also appears to alter the composition of the cell membrane or efflux of the cell, as the mutant showed a different morphology on agar plates than the wild type.

**Conclusions:** The deletion of V320 and G321 in OmpK36 seems to have a significant effect on the resistance of *K. pneumoniae* in combination with production of an OXA-48 carbapenemase. The deletion may cause a structural change of the porin, so that the influx of larger molecules such as carbapenems is decreased. The fitness loss indicates that reduced influx could also affect nutrients.

**Presenter email address:** lisa-marie.hoefken@rub.de
Abstract 5078

**Large variability of unbound active fraction of ceftriaxone in contrast to ciprofloxacin in plasma of critically ill patients**

Tim Ewoldt1, Alan Abdulla*1, Diederik Gommers2, Anouk Edwina Muller1,4, Henrik Endeman2, Birgit Koch1

1Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands, 2Erasmus University Medical Center, Department of Intensive Care, Rotterdam, Netherlands, 3Erasmus University Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands, 4Haaglanden Medical Center, Department of Medical Microbiology, Den Haag, Netherlands

**Abstract third-party references:** Erasmus University Medical Center

**Background:** Traditional antibiotic dosing is not designed for critically ill patients. Severe illness, frequent hypoalbuminemia, and renal failure results in aberrant pharmacokinetics. Protein binding of drugs may vary significantly in critically ill patients, which can lead to high drug clearance and therefore low plasma concentrations and therapeutic failure. Additionally, bound fractions of antibiotics have no therapeutic effect. For ceftriaxone and ciprofloxacin the unbound fractions have been described as 5-15% and 60-70%, respectively. However, data on protein binding of these antibiotics are scarce in critically ill patients. Our objectives were to determine unbound fractions of ceftriaxone and ciprofloxacin in critically ill patients, and to determine predictors affecting the unbound fractions.

**Materials/methods:** Samples were obtained from an ongoing multicentre randomized controlled trail (DOLPHIN) at the intensive care units. Peak and trough samples were collected at 1, 3, and 5 days after initiation of antibiotic therapy. Total and unbound concentrations were determined with a validated mass spectrometry (LC-MS/MS) method. For unbound fractions, we used linear regression to find predictors (p-value <0.10). These predictors were used in a multivariate linear regression (step-down) for each predictor (p-value <0.05).

**Results:** A total of 38 patients (137 samples) receiving ceftriaxone or ciprofloxacin were included. Unbound fractions that exceeded more than 3 standard deviations (outliers) were removed from analysis (N=20). The median [IQR] unbound fractions were 20.2 (15.4-29.4)% and 71.1 (69.4-76.5)% in peak concentrations for ceftriaxone and ciprofloxacin, respectively. For trough concentrations the fractions were 12.3 (8.5-20)% and 69.1 (66.8-73.5)%.

Using multivariate analysis, decreased serum albumin, increased serum creatinine, and septic shock were found to be positive predictors for the percentage of unbound fraction of ceftriaxone trough concentration. Septic shock was the major predictor. No patient characteristics were identified as predictors for unbound fractions of ciprofloxacin.

**Conclusions:** In contrast to the moderately and fairly constant bounded ciprofloxacin, the fraction of unbound concentration was extremely variable in ceftriaxone and especially for trough concentrations, higher than previously reported, resulting in fluctuations in effective exposure. At the moment unbound fraction is not considered when dosing ceftriaxone, but therapeutic drug monitoring unbound trough concentrations might increase the likelihood of therapeutic success.

Abstract 5079

Presence and zoonotic potential of *Escherichia coli* ST131 recovered from wildlife and food-producing animals, with high prevalence of *mcr-1* within porcine isolates

Isidro García-Meníño*1, Alexandra Herrera2, Verónica Gómez3, Susana Viso González1, Vanesa García Menéndez1, Dafne Díaz-Jiménez1, Saskia C Flament-Simon1, Jorge Blanco2, Azucena Mora Gutiérrez1

1University of Santiago de Compostela, Facultade de Veterinaria, Campus Lugo, Lugo, Spain, 2Centro Tecnológico Agroalimentario de Lugo, Unidad Microbiológica LSA-Cetal, Lugo, Spain, 3Laboratorio de Sanidade e Producción Animal de Galicia [LASAPAGA], Lugo, Spain

**Background:** Although the clonal group ST131 is worldwide recognized as a disseminated emerging pathogen that causes extraintestinal infections, few studies have so far analyzed its presence and zoonotic potential within intensive animal food production and wildlife. On the other hand, food production animals have been identified as the main cause of the antimicrobial resistance increase, including to colistin.

**Materials/methods:** A collection of 101 *E. coli* ST131 isolated in Spain (2006-2016) from intensive farming (28 poultry, 18 porcine), meat (29 chicken, 19 pork, two beef) and wildlife (three wild birds and three wild boars), were characterized for their serotypes, phylogroups, clonotypes (CH), sequence types (STs), virotypes, PFGE-macrolactamase profiles, and antibiotic resistances, including extended-spectrum-β-lactamases (ESBLs) and the plasmid-mediated colistin resistance gene (*mcr-1*).

**Results:** Although CH40-22 was the most prevalent clonotype (82.2%) of the 101 ST131 animal isolates, those of porcine origin showed nine different *fimH* allelic variants. Ninety-one isolates satisfied the extraintestinal pathogenic *E. coli* (ExPEC) status. According to their virulence profile, poultry ST131 isolates exhibited the virotype D4 (56 of 57 isolates); porcine isolates conformed mainly to the virotype D5 (17 of 36 isolates), but also virotypes D2 (10) and D4 (four); bovine isolates showed the virotypes D2 (one) and D4 (one), and wildlife isolates the virotypes D1 (two) and D3 (three). Ten ST131 isolates carried ESBL-genes typed as CTX-M-9 (seven poultry isolates), SHV-12 (one poultry) and CTX-M-1 (two porcine). Furthermore, 14 cefoxitin-resistant ST131 (13 poultry and one beef isolates) were carriers of the *bla_CTX-M* gene. The *mcr-1* gene was detected in one beef meat and 12 porcine isolates (seven from pig feces and five from pork meat). We found ≥85% similarity in the PFGE-macrorestriction comparison of porcine virotypes (D2, D5) and poultry virotype D4) meat isolates with ST131 isolates of human origin (Figure 1).

**Conclusions:** Intensive farming and wildlife animals represent significant reservoirs of *E. coli* ST131 potentially pathogenic for humans. Poultry and pork meat could be playing an important role in the transmission of ST131 isolates belonging to the virotypes D4 (chicken), D2 and D5 (pork). Of particular concern is the high prevalence of *mcr-1* within porcine ST131 isolates.

**Figure 1.** PFGE macrorestriction profile of 14 meat *E. coli* ST131 (in blue) compared with 15 human clinical and two avian patholgy isolates of the UREC collection (in black); association between isolation code, virotype, ESBL, year, origin of isolation (PM, pork meat; AM, avian meat; AP, avian patholgy and H, human) and virulence profile is indicated on the right. Highlighted in red clusters of similarity ≥80%.

Abstract 5080

Whole genome sequencing of *Salmonella enterica* from Spanish hospitals with resistance to third generation cephalosporins

Xenia Vázquez1,2*, Vanesa García Menéndez3, María De Toro4, Noemí Rodríguez1, María Margarita Bances5, Miriam Alkorta6, Jesús Rodríguez-Lozano7, Jorge Calvo-Montes8, Javier Fernández2;8, M. Rosario Rodicio2;9

1University of Oviedo, Departamento de Biología Funcional, Área de Microbiología, Oviedo, Spain, 2Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, 3Universidade de Santiago de Compostela, Laboratorio de Referencia de Escherichia coli (LREC), Departamento de Microbiología e Parasitoloxía, Facultade de Veterinaria, Lugo, Spain, 4Centro de Investigación Biomédica, Plataforma de Genómica y Bioinformática, Logroño, Spain, 5Dirección General de Salud Pública, Laboratorio de Salud Pública (LSP) del Principado de Asturias, Oviedo, Spain, 6Hospital Universitario Donostia-IIS Biodonostia, Servicio de Microbiología, San Sebastián, Spain, 7Hospital Universitario Marqués de Valdecilla, Servicio de Microbiología, Santander, Spain, 8Hospital Universitario Central de Asturias (HUCA), Servicio de Microbiología, Oviedo, Spain

**Background:** Resistance to third generation cephalosporins in *Salmonella enterica* is a cause of concern, since these antibiotics are listed by the World Health Organization as critically important with highest priority for human medicine. In the present study, whole genome sequencing (WGS) was used to thoroughly characterize cefotaxime-resistant isolates of *S. enterica* from Spanish hospitals.

**Materials/methods:** Nineteen cefotaxime-resistant isolates of *S. enterica* were recovered from patients attended at three Spanish hospitals between 2012 and 2018. Antimicrobial susceptibility was determined and the obtained results were interpreted according to CLSI guidelines. Genome sequencing was performed with Illumina (2x125 bp paired-end reads). Genome reconstruction, including reads assembly, was done with the PLACNETw pipeline. Serotyping, MLST, identification of resistance genes and plasmid detection/characterization were achieved “in silico” using SeqSero, MLST, ResFinder, CARD, ArgAnot, Plasmid Finder, pMLST and PLACNETw.

**Results:** Of the 19 cefotaxime-resistant isolates, 16 were positive for extended-spectrum \(\beta\)-lactamases (ESBL) and three for AmpC-type \(\beta\)-lactamases. The ESBL-producers carried one of the following genes: \(\text{bla}_{\text{CTX-M}}\) (ten *S. Typhimurium* ST34 isolates, of them one biphasic and nine belonging to its monophasic S. 4,12:i:- variant); \(\text{bla}_{\text{CTX-M-9}}\) (three isolates assigned to *S. Typhimurium* ST19, monophasic S. 4,12:i:- ST34 and *S. Enteritidis* ST11); \(\text{bla}_{\text{CTX-M-14}}\) (two *S. Infantis* ST32); and \(\text{bla}_{\text{CTX-M-1}}\) (one *S. Paratyphi B* ST110). In the three AmpC-producers (one monophasic S. 4,12:i:- ST34 and two *S. Bredeney* ST306), the \(\text{bla}_{\text{CMY-2}}\) gene, was detected. All except the single *S. Typhimurium* ST19 and *S. Enteritidis* ST11 isolates were MDR. Moreover, \(\text{mcr-1}\), \(\text{mcr-9}\) (for plasmid-mediated colistin resistance) or \(\text{qnrA1}\) (for plasmid-mediated quinolone resistance) coexisted with \(\text{bla}_{\text{CTX-M-9}}\) or \(\text{bla}_{\text{CMY-2}}\) in five ST34 isolates. These resistance genes were harbored by IncHI2 (\(\text{bla}_{\text{CTX-M-9}}, \text{mcr-9}, \text{qnrA1}\)), IncF/repB (\(\text{bla}_{\text{CTX-M-9}}\)), IncI (\(\text{bla}_{\text{CTX-M-9}}\) and \(\text{bla}_{\text{CTX-M-1}}\)), IncC (\(\text{bla}_{\text{CMY-2}}\)), IncP (\(\text{bla}_{\text{CTX-M-65}}\)) or IncX4 (\(\text{mcr-1}\)) plasmids, or located on the chromosome (\(\text{bla}_{\text{CMY-2}}\) in a single case).

**Conclusions:** WGS revealed that diverse *S. enterica* serotypes with resistance to third generation cephalosporins, sometimes combined with plasmid-mediated resistance to colistin or fluoroquinolones, are circulating in Spanish hospitals. Most of the detected isolates belong to highly successful clones of *S. enterica*, including the monophasic 4,12:i:- ST34 variant of *S. Typhimurium* and *S. Infantis* ST32.

Abstract 5081

**MiSeq protocol for 16S rDNA community profiling revisited with exact ribosomal sequence variants**

Johannes Matern*, Daniel Hagenfeld1, Karola Prior1, Benjamin Ehmke1, Dag Harmsen1

1University Hospital Münster, Department of Periodontology and Operative Dentistry, Münster, Germany

**Background:** In 2013 Illumina published a 16S rDNA amplicon sequencing protocol. Here the variable region V3 and V4 (V34) is amplified with Kapa HiFi ReadyMix polymerase and sequenced with paired 300-bp reads using standard sequencing-primers (universal tailed-tag dual index design; UTTDI). Recently algorithms using exact ribosomal sequence variants (RSVs) rather than ‘fuzzy’ OTUs have evolved quickly. Therefore, using such a de-noising approach we challenged Illumina’s protocol and compared it against a widely adopted V4 single-step amplification library preparation method using custom sequencing-primers (fusion primer dual index; FPDI).

**Materials/methods:** To assess qualitative and quantitative accuracy an even mock community with 22 bacterial species (with perfect matching amplification-primer sites) was sequenced on a MiSeq. Various libraries were produced in duplicate with paired 250- or 300-bp reads, with V34 or V4, and with UTTDI or FPDI, respectively. Cutadapt was used to remove amplification-primers from UTTDI reads. Then the DADA2 de-noising software was employed run- and library-wise with defaults (most notably zero mismatches between overlapping reads were allowed) except the following: 10-bp from the 5'-end of each FPDI read were trimmed, V4 reads were trimmed if necessary on both ends to achieve fully overlapping merged reads only, and trimmed reads with more than two expected errors were discarded.

**Results:** Each mock community species was detected in all libraries. When comparing 250- vs. 300-bp libraries it was noted that for the latter three times more reads were filtered (22.34 vs. 79.19%, \( p < 0.001 \)). Furthermore, the marginally overlapping V34 libraries had four times more false positive RSVs than V4 libraries (33.83 vs. 8.20%, \( p = 0.026 \)). Finally, the accuracy of mock community quantification expressed as root-mean-square-deviation (RMSD) between observed and expected values was better for UTTDI than FPDI. This effect was even more pronounced when a species with not perfect matching V4 primer annealing sites was added to the mock community (2.97 vs. 3.94 RMSD).

**Conclusions:** Due to possible primer editing quantification of the two-step amplification UTTDI was indeed superior to FPDI. However, for economic and quality reasons it is recommended to update Illumina’s protocol with RSV analysis to 250-bp reads and to fully overlapping V4 libraries, respectively.

**Abstract 5082**

**Evaluation of meningococcal B vaccine antigen variants in Neisseria meningitidis: Italy 2012-2018**

Paola Vacca*, Luigina Ambrosio, Cecila Fazio, Arianna Neri, Annapina Palmieri, Anna Carannante, Paola Stefanelli

1Istituto Superiore di Sanità, Roma, Italy

**Background:** Neisseria meningitidis of serogroup B (MenB) represents currently the leading cause of invasive meningococcal diseases (IMD) in Italy. Two protein-based vaccines are on the Italian market: the four-component vaccine, containing factor H binding protein (FHbp), Neisseria adhesin A (NadA), Neisserial heparin binding antigen (NHBA) and porin A (PorA), and the bivalent vaccine containing two FHbp-subfamily variants. Vaccine antigen variants on MenB strains responsible of IMD in Italy, from 2012 to 2018, were analyzed.

**Materials/methods:** Two-hundred and two isolates and/or clinical samples (blood or cerebrospinal fluid) from IMD were collected and characterized at the National Reference Laboratory of Istituto Superiore di Sanità in Rome. Genotypic characteristics, including serogroup identification, multilocus sequence typing (MLST), and vaccine antigen genes (FHbp, nadA, nhba and porA), were defined using the PubMLST website (http://pubmlst.org/neisseria/).

**Results:** Eighteen clonal complexes (ccs) were identified, of which the cc41/44 (22%) and the cc162 (20%) were the most frequently found. A slightly increase of cc213 was also observed. FHbp variant 1 (subfamily B) was the most commonly detected over time (54%), mostly associated with cc41/44 and cc162. FHbp variants 2 and 3 (subfamily A) were less represented (20% each one) and identified in cc41/44 and cc213, respectively. Full-length NadA peptide was detected in 8% of MenB, mostly belonging to cc32; whereas, the majority has the nadA gene interrupted by the insertion of genetic elements or by deletions. A greatest diversity was observed for NHBA peptide, with NHBA-20 being the prevalent and mainly associated with cc162. PorA VR2 14 was the most frequent, mainly identified in cc162 and cc213.

**Conclusions:** This analysis suggests that the vaccine antigen variants are quite stable over time among the MenB genomes studied. Molecular analysis need to be completed by the antigen expression measure to predict the efficacy of MenB vaccines.

**Colistin-resistant bacteria in Indian raw food samples**
Kulakkattil Abdul Ghafur*, Gnanasoundari Palani, Thirunarayan Ma, Nandini Sethuraman, Prem Kumar, Priethikka Selvakumara, Sheela Nagusah, Roshni Antony

*Apollo Cancer Institute, Chennai, India*

**Background:** Usage of colistin as a growth promoter in livestock farms is a well-known factor contributing to colistin resistance. An earlier single publication from Chennai, India reported the presence of colistin resistant bacteria in raw food samples. Aim of the current study was to analyse the extent of the problem in a larger sample size.

**Materials/methods:** Food samples like chicken, fish, meat and vegetables were collected from multiple sources such as households, supermarkets and outlets in Chennai, between November 2018 and October 2019. Approximately one gram of minced food sample was inoculated in 9ml of Brain heart infusion broth. After overnight incubation, 1ml of suspension was enriched overnight in BHIB containing colistin (10 µg colistin disk/colistin sulfate). 50 µl of sample was inoculated in ChromID Colistin R agar plates and incubated for 24 to 48 hours. Species with intrinsic resistance to polymyxins were discarded. Colonies recovered were identified by MALDI-TOF MS and antimicrobial susceptibility testing was performed using Vitek-2 system. Colistin MIC was determined using broth microdilution method.

**Results:** A total of 381 food samples (251 vegetables, 52 fruits, 69 chicken, 8 mutton and 1 fish) were analysed. 93/381 food samples (39 chicken, 4 mutton, 41 vegetables and 9 fruits) carry colistin resistant isolates. 121 colR isolates were identified including 82 K. pneumoniae, 1 K. aerogenes, 8 E. coli, 7 Enterobacter spp, 2 Cronobacter spp., 2 Salmonella enterica, 19 P. aeruginosa. Klebsiella species showed high colistin MIC ranging from 4 to ≥256µg/ml and 51% of these are sensitive to all the tested antibiotics. E. coli shows colistin MIC of 4 to 16µg/ml with resistance to cotrimoxazole and fluoroquinolone. All Enterobacter isolates had colistin MIC of ≥256µg/ml and were susceptible to other tested antibiotics. Other species (Cronobacter, Salmonella) shows colistin MIC 4 or 8 µg/ml. Colistin MIC of P. aeruginosa ranges from 4 to 16 µg/ml.

**Conclusions:** Presence of colistin resistant bacteria in a large number of community food samples is extremely worrying. The recent Indian ban on growth promotional usage of colistin is encouraging but the implementation must be systematically monitored.

Prevalence and molecular epidemiology of high-risk clones among third-generation cephalosporin-resistant and carbapenem-resistant Klebsiella pneumoniae in Germany

Kyriaki Xanthopoulou*1;2, Julia Wille1;2, A. Sarah Walker1;2, Yvonne Stelzer1;2, Vivien Persy1;2, Can Imirzalioglu3;4, Kai Lucassen2, Harald Seifert1;2, Paul G. Higgins1;2

1University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research (DZIF), Partner site Bonn-Cologne, Cologne, Germany, 3Justus-Liebig University, Institute of Medical Microbiology, Giessen, Germany, 4German Center for Infection Research (DZIF), Partner site Giessen-Marburg-Langen, Giessen, Germany

Abstract third-party references: for the DZIF-R-NET Study Group

Background: The increase of multidrug resistant (MDR) Klebsiella pneumoniae (Kpn) reflects a complex dissemination process including mobile genetic elements and the spread of high-risk (HiR) MDR clones. We aimed to investigate the prevalence of HiR-clones and the molecular epidemiology of third-generation cephalosporin-resistant (3GCR) and carbapenem-resistant (CR) Kpn recovered from patients on hospital admission, and from bloodstream infections (BSI) in Germany.

Materials/methods: Patients were screened upon hospital admission in 2016 and 2017 for rectal colonization of 3GCR and CR Kpn at six German tertiary-care university hospitals. Isolates were selected using chromID ESBL (bioMérieux) and CHROMagar mSuperCARBA (Mast Diagnostica). 3GCR, CR and susceptible Kpn BSI isolates were included. Antimicrobial susceptibility testing for cefotaxime, ceftazidime, ertapenem, imipenem, and meropenem was performed using Vitek2 and Etest (bioMérieux). Sequencing libraries were prepared for 250bp paired-end sequencing on a MiSeq (Illumina). Core-genome MLST (Ridom® SeqSphere+) and 7-loci MLST were determined.

Results: Out of 5846 patients screened on hospital admission, 41 3GCR Kpn isolates were recovered (0.7% prevalence), of which five were additionally CR (carbapenemase negative). The most common STs were ST45 (n=4), ST14 (n=3), ST17 (n=3), ST20 (n=2) and ST307 (n=2). Among the colonizing Kpn, 22% belonged to HiR-clones (ST14, ST17, ST37 and ST307). A total of 47 3GCR Kpn isolates were recovered from BSI, of which two were also CR (OXA-48-encoding). The most prevalent STs among the BSI were ST15 (n=5), ST48 (n=5), ST307 (n=5), ST13 (n=3), and ST101 (n=3), while, 43% belonged to HiR-clones (ST14, ST15, ST17, ST101 and ST147). By cgMLST, an unambiguous separation of isolates was observed with only a few clusters detected among colonizing and infecting isolates. A total of 26 susceptible Kpn from BSI were investigated. Here, ST37 (n=4) was the most prevalent ST followed by ST14 (n=2) while no transmission clusters were detected and 31% belonged to HiR-clones (ST14, ST17, ST37, and ST101).

Conclusions: Our data demonstrate that the prevalence of 3GCR Kpn carriage on hospital admission remains low, and that CR is still rare. Clusters were rarely observed among colonizing and infecting isolates. Finally, our results indicate that international HiR-clones are circulating in Germany forming small clusters.

Background: To date comparative studies on the efficacy of echinocandins compared to azoles in patients with liver cirrhosis are lacking. Patients affected by liver cirrhosis represent a particular setting as they present a higher risk of fungal infections and an altered pharmacokinetic and pharmacodynamics.

Materials/methods: A retrospective multicenter study base on four Italian tertiary hospitals has been conducted including adult patients with liver cirrhosis and candidemia between 2014 and 2018. Patients were followed-up for 30 days after infection onset. Patients receiving antifungal regimen containing or non-containing echinocandins were compared. Factors associated to 30-day mortality were evaluated with a propensity-score adjusted multivariable analysis.

Results: Ninety patients were included. Of these, 63% were male with a median age (interquartile range) of 63 years (52-68). The cirrhosis etiologies were HCV infections (50%) and alcoholic abuse (29%). The main species of Candida spp. found in these patients were Candida albicans (64%), Candida parapsilosis (14%) and Candida glabrata (9%). Of the 90 cases analyzed, 76 had performed adequate targeted therapy, 41 out of 76 had been treated with fluconazole, 32 out of 76 with an echinocandin and 3 out of 76 with liposomal amphotericin-B. Overall, the 30-day mortality rate from candidemia was 42%. Survival analysis using Kaplan-Meier curves showed a significant lower mortality among patients treated with echinocandins (25% vs 50%; p 0.038). In the multivariate analysis the 30-day mortality predictive factors were: MELD calculated at the time of diagnosis of candidemia [HR 1.058 (95% CI 1.004- 1.117); p 0.035], septic shock [HR 3.084 [95% CI 1.422- 6.686]; p 0.004], whereas echinocandin therapy was associated with a better survival rate [HR 0.415 [95% CI 0.165-0.983]; p 0.046]. Echinocandin therapy remained highly associated with a better survival rate also after propensity score adjustments [HR 0.271 [95% CI 0.096-0.772] p = 0.014].

Conclusions: Despite the limitations related to population size and the retrospective study design, we have been able to show a greater clinical efficacy of echinocandins in the treatment of candidiasis in patients affected by liver cirrhosis.

Are large cities at higher risk for tuberculosis drug resistance? A French appraisal

Sheila Chiesi*1, Lorenzo Guglielmetti1,2, Marwa Bachir1, Alexandra Aubry1,2, Nicolas Veziris1,2, Nadine Lemaitre3, Jérôme Robert1,2

1Sorbonne Université (U1135-E113), Centre d'Immunologie et des Maladies Infectieuses, Paris, France, 2Sorbonne Université, Centre National de Référence des Mycobactéries et de la résistance aux antituberculeux, AP-HP, Paris, France, 3Chu De Lille, Laboratoire de Bactériologie-Hygiene, Centre de Biologie-Pathologie, Lille, France

Background: Tuberculosis burden in France is low (<10 cases/100 000), but the national average conceals regional disparities, with some parts of Ile-de-France at higher risk. These differences are mainly linked to immigration from high-burden countries or rates of human immunodeficiency virus (HIV) infection. We sought to investigate if Paris or large French cities had a higher prevalence of drug resistance, and, eventually, reasons for epidemiological disparities.

Materials/methods: Socio-demographic and microbiological data were routinely collected from 1998 to 2017 via a sentinel network of 36 laboratories of University Hospitals (AZAY-Mycobacteria network) that complied with the international recommendations for the surveillance of drug resistance and performed drug susceptibility testing. Participating laboratories were divided into 4 groups according to the region or the size of the city: Paris, Ile-de-France except Paris [sub-urban Paris], and cities larger or smaller than 200 000 inhabitants. Paris was considered the reference for comparisons.

Results: Overall, the network collected data on 30 727 patients; globally, 34% were diagnosed in Paris. Compared to the 3 other regional groups, patients from Paris were younger, more likely to be male, HIV-positive and foreign-born. Resistance to at least one first-line anti-tuberculosis drug (14% in Paris vs 11% in Ile-de-France, 11.4% in big cities, 10% in small cities), and multidrug-resistant tuberculosis (MDR-TB) (3% vs 1.5%, 2%, 2%, respectively) were significantly higher in Paris. In multivariable analysis, being diagnosed in Paris was independently associated with primary and secondary resistance to at least one first-line drug. Being diagnosed in large cities was associated with secondary resistance. Other factors independently linked to resistance were age <41 years, sputum smear positivity and being foreign-born (Table 1).

Conclusions: Resistance rates to anti-tuberculosis drugs are higher in Paris than in other large or small French cities. Moreover, Paris was independently linked to a higher risk of primary and secondary drug resistance. This risk is not explained by traditional risk factors such as treatment history and country of birth. Specific socio-demographic features should hence be sought to explain the higher burden of resistant tuberculosis in Paris compared to other districts in France.

Abstract 5088

Trends in Gram-negative bacteraemia in adult febrile neutropaenic cancer patients in a high-resistance setting during the last decade

Caglayan Merve Ayaz¹, Emre Bilgin², Gülşen Hazırolan³, Banu Sancak³, Murat Akova*¹

¹Hacettepe University Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Ankara, Turkey, ²Hacettepe University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey, ³Hacettepe University Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey

Background: We analyzed the trends in gram-negative (GN) bacteremia and changes in antimicrobial resistance patterns in febrile neutropenic (FEN) patients with hematological malignancies (HMs) and/or hematopoietic stem cell transplantation (HSCT). Antibiotic resistance profile was determined for extended spectrum beta lactamase (ESBL) production, carbapenem resistance (CR), multidrug-resistant phenotype (MDR) and colistin resistance.

Materials/methods: 296 blood isolates from 286 patients hospitalized between 1.1.2010 and 31.5.2019 at Hacettepe University were evaluated. Only the first bacteremic episode for each patient was included in analysis. BD Phoenix™, VITEK-MS (BioMérieux) and Bruker Biotyper Matrix-Assisted Laser Desorption/Ionization-Time of Flight automated identification systems were used to identify bacteria over the years. VITEK® 2 Compact System and BD Phoenix was used for antibiotic susceptibility, if necessary conventional methods were also employed. ESBL detection was performed by E-test until 2017 and double disk synergy test+combine disk test were used after 2017. MDR phenotype was as described previously (Magiorakos et al. Clin Microbiol Infect 2012;18:268). Kruskal-Wallis test was used to calculate the ratios between resistance mechanisms that changed between years and Jonckheere-Terpstra test was used to evaluate the changing trends between these ratios.

Results: 153 E. coli, 52 K. pneumoniae, 36 P. aeruginosa, 31 A. baumannii and 26 other GN bacteria were isolated during study period. A significant increase was detected in ESBL-production (p=0.05) and MDR phenotype [p<0.001] in E. coli related bacteremia. ESBLs production [p<0.001], MDR phenotype [p<0.001] and CR [p<0.001] have also increased in K. pneumoniae isolates. The variation of antimicrobial resistance over the years in all bacteria is shown in the Figure. Colistin resistance was rare and detected in one each E. coli (0.6%), P. aeruginosa (2.7%), A. baumannii (3.2%) and, 2 K. pneumonia (3.8%) strains. No significant difference was found in other bacteria.

Conclusions: In our center, high-risk HM and HSCT patients have exposed to an increased rate of resistant enteric and non-fermentative GN bacterial pathogens. Since standard empirical regimens may not work in such a high-resistance setting, strategies should be regularly updated according to current epidemiological data.

Presenter email address: counsellor@escmid.org
Sequential time-kill curve to distinguish polymyxin-induced resistance and hetero-resistance in Acinetobacter baumannii

Hariyanto Ih*1,2, Nicolas Gregoire1,3, William Couet1,3, Sandrine Marchand1,3, Julien Buyck1

1Université de Poitiers, INSERM U1070 - Faculté de Médecine et de Pharmacie, Poitiers, France, 2Universitas Tanjungpura, Pharmacy Department - Faculty of Medicine, Pontianak, Indonesia, 3Centre Hospitalier Universitaire (CHU) de Poitiers, Service de Toxicologie et de Pharmacocinétique, Poitiers, France

**Background:** Resistance to polymyxins, the last therapeutic option for multidrug-resistant A. baumannii, is increasingly reported. In this study, sequential time-kill experiments were used to describe the adaptive resistance to colistin and polymyxin B in A. baumannii and modifications of genes involved in polymyxin resistance were characterized by sequencing and RT-qPCR.

**Materials/methods:** Two A. baumannii clinical isolates from the same patient were used in this study: a colistin-susceptible (ColS) and a colistin-resistant after colistin treatment (ColR). Two sequential time-kill curve (TKC) were performed using colistin (CST) and polymyxin B (PMB) at concentration from 0.25x to 64x MIC. The bacteria that regrowth in presence of polymyxins from 1st TKC were directly used for the next 2nd TKC inoculum. In parallel, heteroresistance was quantified by population analysis profiles (PAPs). Alongside, bacteria were analyzed by sequencing and RT-qPCR to determine the change of genes involved in lipopolysaccharide (LPS) modifications (pmrA, pmrB, pmrC, lpxM) and LPS biosynthesis (lpxA, lpxC, lpxD).

**Results:** Sequential TKC have shown that after 2nd TKC, ColS could growth up to 8-fold MIC to CST, but not with PMB. Also, high-level colistin resistant population was shown by ColR after 2nd TKC with the highest regrowth up to 16-fold MIC for CST but only 4-fold for PMB observed from their respective MICs value. Before the contact with polymyxins, genes sequences of pmrA, pmrC, lpxM, lpxA, lpxC, and lpxD for both isolates were identical except for pmrB that shown the addition of 10-amino acid followed by an overexpression of pmrA (5-fold), pmrB (8-fold) and pmrC (3.9-fold) for ColR. PAPs confirmed the presence of resistant subpopulation with dissimilarity genetic expression in ColR but not in ColS. No other mutations were found in ColS and ColR after 2nd TKC. However, after 2nd TKC, a significant overexpression of lpxC was shown by ColR regrowth isolates only with CST (5-fold) but not with PMB.

**Conclusions:** The colistin-susceptible A. baumannii was able to develop resistance under colistin pressure while it remains susceptible to polymyxin B. We also showed that the high-level colistin resistant in ColR was presumably caused by heteroresistance population associated to loss of LPS production.

Abstract 5090

Rapid detection of bacteria resistant to the last resort antibiotics using MALDI Biotyper Sirius: the MALDIxin test

Christopher Furniss1, Laurent Dortet1, Remy Bonnin2, Simon Le Hello3, Katrin Sparbier4, Oliver Drews4, Alain Filloux4, Markus Kostrzewa4, Despoina Mavridou1, Gerald Larrouy-Maumus*1

1Imperial College, London, United Kingdom, 2Bicêtre Hospital, Assistance Publique - Hôpitaux de Paris, Paris, France, 3French National Reference Centre for Salmonella, Paris, France, 4Bruker Daltonik GmbH, Bremen, Germany

Background: Resistance to polymyxins in most Gram-negative bacteria arises from chemical modifications to the lipid A portion of their lipopolysaccharide [LPS] mediated by chromosomally-encoded mutations or the recently discovered plasmid-encoded mcr genes that have further complicated the landscape of colistin resistance. MIC determination by broth microdilution, the gold standard for the detection of polymyxin resistance, is time consuming (24 hours). This is why there is a need for fast, robust, accurate, easy to use and affordable diagnostics solutions to detect polymyxin-resistant bacteria, providing a same-day-result after species identification.

Materials/methods: 40 E. coli clinical isolates and a collection of 23 Salmonella enterica clinical strains were used in this study. Briefly, bacteria grown on Mueller-Hinton agar were submitted to mild-acid hydrolysis (1 % acetic acid, 98°C for 10 min). Washed hydrolyzed cells were loaded onto the MALDI target plate and immediately overlaid with 1.2 μL of matrix (super-DHB matrix, dissolved in chloroform/methanol 90:10 v/v to a final concentration of 10 mg/mL). The bacterial suspension and matrix were mixed directly on the target by pipetting and the mix dried gently under a stream of air. MALDI-TOF mass spectrometry analysis were performed with a MALDI Biotyper Sirius (Bruker Daltonics) using the linear negative-ion mode.

Results: We calculated Polymyxin resistance ratio (PRR) values from the acquired spectra. The percentage of modified lipid A was calculated by dividing the sum of the intensities of the lipid A peaks attributed to addition of pETN (m/z 1919.2 and m/z 2157.2) and L-Ara4N (m/z 1927.2 and m/z 2165.2) by the intensity of the peaks corresponding to native lipid A (m/z 1796.2 and m/z 2034.2); a PRR value of zero, indicating polymyxin susceptibility, was obtained for all colistin-susceptible isolates, whereas positive PRR values, indicating resistance to polymyxins, were obtained for all resistant strains. In Salmonella the average percentage of modified lipid A remained significantly lower in chromosome-encoded colistin resistant isolates (18.25% ± 3.23%) compared to MCR-producers (51.12% ± 3.38%).

Conclusions: Thanks to its speed of execution, affordability and ease to use, the MALDIxin test using MALDI Biotyper Sirius might be a game changer in antimicrobial susceptibility testing and patient management.

Abstract 5091

**Design of a varicella zoster virus PCR combined with a herpes simplex virus PCR in a multiplex assay: a diagnostic evaluation study**

Bettina Schmid*1;2, Marianne Affolter1, Antonio Buttafuoco1, Martin Glatz1;2, Philipp Bosshard1;2

1University Hospital Zürich, Zürich, Switzerland, 2University of Zürich, Zürich, Switzerland, 3MCL Medizinische Laboratorien AG, Niederwangen, Switzerland

**Background:** Herpes simplex virus 1 and 2 (HSV-1/-2) and varicella zoster virus (VZV) typically infect the skin and mucosa. They can also affect the nervous system and lead to serious neurological complications. These infections have a wide spectrum of differential diagnoses. Thus, a fast and reliable detection is crucial. For this purpose, we evaluated a new VZV PCR and its combination in a multiplex format with an existing HSV-1/-2 assay to form a vesicular rash PCR.

**Materials/methods:** We designed primers and probes for VZV and an internal control and combined them with existing primers and probes for HSV-1/2 [Corey et. al. J Med Virol; 2005; 76. 350-355]. DNA extracts from 276 skin and mucosal swabs were tested with the new multiplex PCR and the commercial Artus VZV and HSV-1/-2 PCR kits, which were considered as gold standard.

**Results:** None of the samples was inhibited. Results of the new PCR and the commercial kits are compared in the 2x2 contingency table [table 1]. The overall concordance was >99%. Sensitivity, specificity, PPV and NPV of the new PCR were perfect for VZV and HSV-2 (100% each), and 100%, 99.4%, 97.0% and 100% for HSV-1, respectively.

**Conclusions:** The new VZV-HSV-1/-2 vesicular rash multiplex PCR has excellent sensitivities, specificities, PPVs and NPVs for diagnosing the three herpesviruses and is suitable for usage in routine clinical practice.

Abstract 5096

**The REAnimation Low Immune Status Markers study: phenotypic and functional alterations of innate immune response in critically ill patients**

Virginie Moucadel*, Fabienne Venet1, Julien Textoris1, Sophie Blein1, Mary Luz Rol1, Bertrand Canard2, Pierre Cortez3, Lionel Tan4, Laurence Quemeneur5, Andrew Griffiths6, Estelle Peronnet1, Alexandre Pachot1, Guillaume Monneret1, Thomas Rimmelé1

1EA 7426 « Pathophysiology of Injury-Induced Immunosuppression » (Université Claude Bernard Lyon 1 - Hospices Civils de Lyon - bioMérieux), Joint Research Unit HCL-bioMérieux, Immunology Laboratory & Anesthesia and Critical Care Medicine Department, Edouard Herriot Hospital, Lyon, France, 2Bioaster Technology Research Institute, Lyon, France, 3Sanofi Aventis, Chilly-Mazarin, France, 4GladSmithKline, Cambridge, United Kingdom, 5Sanofi Pasteur, Marcy-l’Étoile, France, 6ESPCI Paris, PSL Research University, Paris, France

**Background:** Immune response to sepsis is complex. Several alterations of the innate response have been described and some even observed in other severe injuries. However, the comprehensive description of immune alterations development overtime in a large cohort of patients has never been done so far. In addition, it is not known whether these alterations depend on the type of injury (infectious vs sterile) and if they are associated with an increased risk of deleterious outcomes.

**Materials/methods:** A prospective longitudinal observational study was set up in Edouard Herriot Hospital (Lyon-France, December 2015 - March 2018). A total of 354 ICU patients suffering from sepsis, severe trauma or after major surgery, and 175 healthy volunteers were enrolled. Blood specimens were collected once for volunteers and three times for patients during the first week of ICU stay. Systemic inflammation was monitored by measuring IL-6 and IL-10 plasma concentrations. The innate response was measured by assessing cell numbers, phenotypes (immature neutrophils, MHC class II expression on monocytes), functions (cytokine production), and mRNA levels (S100A9, CD74, CX3CR1) with standardized tests.

**Results:** Injury-induced innate immune profile was similar in the 3 groups of patients and characterized by a major rise of circulating immature neutrophils number and proportion whereas the number of circulating monocytes was not modified. However, starting from D1 after injury, monocytes were characterized by a major decrease in MHC class II expression correlated with altered TNFalpha production to LPS ex vivo. Intensity of these injury-induced alterations was maximal at D1, inversely correlated with systemic pro and anti-inflammatory responses and decreased overtime. The persistence at the end of the first week after injury of profound monocyte alterations was associated with an increased risk of death and secondary infections.

**Conclusions:** Our results show the complexity and overtime evolution of the innate immune response after injury. This response combines an initial physiologic stress immune response with the concomitant development of monocyte alterations. When persisting, these alterations are associated with deleterious outcomes in accordance with the development of delayed injury-acquired immunodeficiency. Our data support the rational for an immune intervention to restore functional immune response in these patients.

**Abstract 5097**

**Human polyomaviruses in the cerebrospinal fluid of neurological patients**

Serena Delbue1, Diego Franciotta2, Maria Dolci1, Signorini Lucia1, Rosalia Ticozzi1, Sarah D’alessandro1, Giuseppina Campisciano1, Manola Comar3, Pasquale Ferrante1, Marco Ciotti4

1University of Milan, Milan, Italy, 2IRCCS Mondino Foundation, Pavia, Italy, 3IRCCS “Burlo Garofolo”, Trieste, Italy, 4Polyclinic Tor Vergata Foundation, Rome, Italy

**Background:** Human Polyomavirus (HPyVs) infections are common, ranging from 60% to 100% of the general population, depending on the virus. After primary infection, which occurs asymptptomatically during childhood, HPyVs can establish a life-long latency in different body compartments. A profound immunological impairment is a risk factor for their reactivation that may lead to clinically severe polyomaviruses-induced diseases. Central nervous system (CNS) tropism is well defined for JC Polyomavirus (JCPyV) while data regarding other HPyVs, such as BK Polyomavirus (BKPyV), Merkel Cell Polyomavirus (MCPyV) and Polyomaviruses 6, 7 and 9 (HPyV6-7-9) are only sporadic in the literature.

**Materials/methods:** A total of 234 cerebrospinal fluid (CSF) samples were collected from patients affected or with suspected different neurological disorders. DNA was isolated and subjected to real-time PCR for the detection of six HPyVs: JCPyV, BKPyV, MCPyV, HPyV6, HPyV7 and HPyV9. When possible, viral strains molecular characterization of JCPyV, BKPyV and MCPyV positive samples was carried out by nested PCR and automated sequencing.

**Results:** Overall, HPyV genomes were detected in 41/234 (17.5%) CSF samples. JCPyV was detected in 3/234 (1.3%), BKPyV in 15/234 (6.4%), MCPyV in 22/234 (9.4%), and HPyV6 in 1/234 (0.4%) CSF samples. BKPyV and MCPyV were significantly more frequently detected than JCPyV (p<0.05). JCPyV was detected at the highest (p<0.05) mean load (3.7 x 10^7 copies/mL), followed by BKPyV (1.9 x 10^6 copies/mL), MCPyV (1.9 x 10^5 copies/mL), and HPyV6 (3.3 x 10^4 copies/mL). Viral protein 1 gene (VP1) gene sequence analysis showed one 1b strain for JCPyV, four Ia strains and three Ib-I strains for BKPyV. Noncoding control regions (NCCRs) gene sequence analysis showed two rearranged strains for JCPyV, four rearranged strains for BKPyV, four rearranged strains for BKPyV and five IIC strains for MCPyV.

**Conclusions:** HPyVs other than JCPyV were found in the CSF of patients affected with different neurological diseases suggesting that HPyVs are latent in the CNS of immunosuppressed patients probably as bystanders, rather than etiological agents of the disease. Furthermore, the description of CNS-infecting viral strains represent an additional benefit allowing the definition of the genotype and/or the rearrangements of HPyVs, other than JCPyV, circulating in the CSF.

Haemophilus influenzae as the causing pathogen of epididymo-orchitis: a case report

Thomas Demuyser1, Kristof Vandoorslaer1, Steve Jacobs1, Luc Van Dijck1, Denis Pierard1

1UZ Brussels, Vrije Universiteit Brussel, Brussels, Belgium

**Background:** Haemophilus influenzae is a Gram-negative opportunistic coccobacillary pathogen of the respiratory tract. This case study reports the rare finding of *Haemophilus influenzae* in the urine of a patient suffering from scrotal pains and mictalgia. At the emergency department of a tertiary hospital in Belgium, the 44 years old patient presents afebrile with inguinal bilateral pain and pus secretion at the start of micturition. The diagnosis of epididymo-orchitis was based on clinical findings; a urine sample was collected for molecular detection of sexual-transmitted disease and bacterial culture. He was released from the ward with anti-inflammatory medication and ciprofloxacin.

**Materials/methods:** Urine sediment analysis was conducted on the Sedimax [Menarini] automated microscope. Next, the urine sample was cultured on a cysteine lactose electrolyte deficient agar. After overnight aerobic incubation at 35°C, primary detection of suspicious colonies from the axenic culture was performed and a subculture was incubated overnight at 5% CO2 at 35°C on a haemophilus agar. Identification of the species was conducted, applying the Biotyper matrix assisted laser desorption/ionisation time-of-flight analyzer [Bruker] together with hemin and nicotinamide-adenine-dinucleotide growth factors verification. Susceptibility testing was subsequently performed.

**Results:** The microscopic urine analysis depicted a pyuria with 2761 leucocytes / µL, with a negative molecular assay for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. After overnight incubation the cysteine lactose electrolyte deficient agar revealed a massive (> 100,000 colony-forming units / mL) growth of small, opaque colonies. Identification of *Haemophilus influenzae* with the Biotyper device was achieved with a matching score >2. Next, confirmation of the species *Haemophilus influenzae* was achieved applying both hemin and nicotinamide-adenine-dinucleotide growth factors on the haemophilus agar. The strain of *Haemophilus influenzae* tested susceptible for ampicillin (MIC = 0.75 mg/L) and resistant for trimethoprim/sulfamethoxazole (MIC = 3 mg/L). The patient’s antibiotic treatment was adapted.

**Conclusions:** Routine urine culture at our laboratory does not include a haemophilus agar, although it provides the necessary nutrients to support growth of *Haemophilus* spp. As such the incidence of the species in urinary samples could be underestimated, yet a literature search does not support the incidence of Haemophilus-associated urinary tract infection to be greater than 1%.

Abstract 5105

**Immunochromatographic detection of quorum-sensing autoinducers, an innovative strategy to diagnose infections by identifying Staphylococcus aureus strains**

Enrique Jose Montagut Cañete1,2, Gerard Godoy3,4, Juan Pablo Salvador1,2, Alicia Lacoma2,3,4, Cristina Prat2,3,4, M.-Pilar Marco1,2

1Instituto de Química Avanzada de Cataluña (IQAC-CSIC), Barcelona, Spain, 2CIBER - Center for Biomedical Research Network, Madrid, Spain, 3Hospital Universitari Germans Trias i Pujol, Badalona, Spain, 4IGTP, Badalona, Spain

**Background:** Staphylococcus aureus is one of the most commonly isolated microorganisms in both healthcare-associated and community-acquired infections. Most common routine diagnostic methods rely on culture-based techniques which can take up to 72h in order to obtain conclusive results. Many bacterial identification alternatives have emerged as potential alternatives of the gold standard culture plate techniques. Particularly, bacterial Quorum Sensing (QS) has attracted the attention as potential diagnostic and therapeutic target. This communication system is based on the release and sensing of low molecular weight chemical signals, called autoinducers (AIs). They control its own biosynthesis and the genetic expression of virulence factors and survival mechanisms. In S. aureus these molecules correspond to cyclic thiolactone peptides (AIPs), encoded by a specific locus, responsible of the phenotypic variability between the different strains.

**Materials/methods:** Monoclonal antibodies against the AIP-4 of S. aureus have been produced after appropriate hapten design and synthesis followed by preparation of the immunogen. A competitive indirect microplate-based ELISA has been developed and implemented to the analysis of biological samples. Clinical isolates from patients proven to be infected by agr-IV strains of S. aureus have been cultured and the profile of AIP-4 secreted to the media has been investigated.

**Results:** The microplate-based ELISA developed with the antibodies produced has shown a limit of detection below the AIP-4 concentration levels in culture broth samples. Quantifiable AIP-4 levels can be detected only after two hours of culture of clinical isolates obtained from patients infected with this pathogen. Culture samples from different agr strains did not show significant immunoreactivity, indicating the potential of the technology to discriminate between the different agr strains.

**Conclusions:** The specific quantification of this QS molecule could provide valuable information regarding the strain type and disease status. The diagnostic tool here presented may significantly contribute to improve diagnostic efficiency and current therapeutic strategies. Immunochemical techniques might be able to fulfill the requirements and demanding challenges of the infectious diseases diagnostic field through the study of QS.

![Figure 1: AIP-IV concentration in culture growth samples from a clinical isolate of S. aureus.](image)

Polyethylene glycol (15)-hydroxystearate enhances amphotericin B activity against Mucorales

Kevin Brunet*1,2,3, Alexia Chauzy1,2, Nicolas Gregoire1,2,3, Frederic Tewes1,2, William Couet1,2,3, Sandrine Marchand1,2,3, Blandine Rammaert1,2,3

1INSERM U1070, Poitiers, France, 2University of Poitiers, Poitiers, France, 3Poitiers University Hospital, Poitiers, France

Background: Amphotericin B (AmB) is the first line therapy recommended to treat mucormycosis. Despite treatment, mortality reaches 40 to 60%. Increasing the efficacy of AmB by using it in combination with an adjuvant could help address this issue. Polyethylene glycol (15)-hydroxystearate (PEG15HS), an FDA-approved surfactant for parenteral use, could destabilize fungal membrane by surfactant activity and thus promote AmB activity which acts through pore formation at the fungal membrane. The aim of our study was to evaluate in vitro the combination of AmB and PEG15HS on several Mucorales strains using this model.

Materials/methods: Chequerboard in RPMI following EUCAST guidelines were used to test interaction between PEG15HS and AmB. AmB diluted in RPMI (4 to 0.002 mg/L) and PEG15HS diluted in sterile water (2752 to 0.042 mg/L) were used. Twelve clinical strains of Mucorales were used: Rhizopus arrhizus (5), Lichtheimia corymbifera (3), Lichtheimia ramosa (1), Rhizopus microsporus (1), Mucor circinelloides (1), Rhizomucor pusillus (1). MIC of AmB were read after 24H at 37°C. The modeling of the effect of PEG15HS on the antifungal efficacy of AmB was performed using an inhibitory Emax model with WinNonlin software.

Results: All strains presented MIC ≤ 1 mg/L for AmB and MIC > 1024 mg/L for PEG15HS. PEG15HS enhanced efficacy of AmB against all strains with 2.5 to 38-fold MIC decrease depending on strain. Potency of PEG15HS was high, with EC50 varying from 0.13 to 1.54 mg/L for 10 strains but was lower for the two others (8.57 and 53.45 mg/L).

Conclusions: PEG15HS highly enhanced AmB activity against Mucorales with high efficacy and potency. Due to PEG15HS low toxicity, high potency, and the need of low concentrations, AmB - PEG15HS combination could improve mucormycosis treatment. Further studies are needed to evaluate pharmacokinetics of PEG15HS and its efficacy in vivo.

Presenter email address: kevin.brunet@univ-poitiers.fr
Abstract 5107

**Distribution of mecA in Staphylococcus aureus isolates in a multi-centre clinical study**

Adam Thornberg*, Natalie Whitfield¹, Deirdre Trainor¹, Jennifer Reid¹

¹GenMark Diagnostics, Carlsbad, United States

**Background:** The mecA gene encodes the penicillin-binding protein 2a (PBP2a) that confers resistance to methicillin and other penicillinase resistant beta-lactams.¹ Most molecular diagnostic tests which detect Staphylococcus spp. and S. aureus, include detection of mecA to alert the laboratory to the presence of resistant Staphylococcus. In the instance of multiple Staphylococci present in a sample, some nucleic acid tests cannot delineate which species carries the mecA. In this study, we evaluate the distribution of mecA among isolates identified as S. aureus by standard of care laboratory methods (SOC) in samples collected from 10 sites to determine how often MRSA was associated with the detection of mecA and how often another Staphylococcus spp. was present using the ePlex® Blood Culture Identification Gram-Positive (BCID-GP) Panel.

**Materials/methods:** There were 1,195 evaluable samples for S. aureus in the clinical study. Each organism was identified by MALDI-TOF MS, automated identification systems, or manual methods and tested by phenotypic antimicrobial susceptibility testing (AST). Samples were tested with qPCR and bidirectional sequencing to determine presence of the mecA. There were 160 prospective and 122 retrospective samples determined to be true positive for S. aureus.

**Results:** The BCID-GP Panel detected S. aureus with mecA in 78 prospective samples. SOC AST results confirmed 90% were MRSA. 98% of S. aureus with no mecA detected were confirmed as MSSA by corresponding AST. No additional Staphylococci were present in prospective samples. In the retrospective samples, S. aureus with mecA was detected in 103 samples and confirmed by AST as MRSA in 99% of samples. One S. aureus and S. epidermidis co-infection with mecA was confirmed as MSSA. In 15 samples with S. aureus with no mecA detected, 14 were confirmed as MSSA including one co-infection with S. capitis.

**Conclusions:** The ePlex BCID-GP Panel exhibits high correlation for the detection of S. aureus and mecA for MRSA and MSSA. Amongst prospective samples collected across 7 major laboratories, no instances of S. aureus with another Staphylococci were found by SOC, whereas only 2 instances were found in retrospective samples from 8 major laboratories. This suggests that prevalence of co-infections may be low.

Evaluation of 16S rRNA metagenomics workflow performance by spike-in and in silico experiments

Valentin Scherz1*, Sebastien Aeby1, Gilbert Greub1, Claire Bertelli1

1Lausanne University Hospital and Lausanne University, Institute of Microbiology, Lausanne, Switzerland

Background: Microbiota profiling by metagenomics is establishing as a standard analysis in clinical microbiology. Despite wide and rapid developments, there is still a great heterogeneity in applied methods. Laboratories must carefully set their workflow since variations in protocols significantly impact results. We present a 16S rRNA metagenomics workflow validation study focusing on DNA extraction methods and taxonomic classification.

Materials/methods: Our workflow was evaluated on the ATCC-2002 mock-community, a commercial control composed of 20 bacteria in even proportions. Samples were prepared in triplicates by spiking serial 10-fold dilutions of this community (5x10^6 to 10^3 bact/ml) into A549 pneumocytes (10^4 cells/ml). DNA was extracted with Ultra-Deep Microbiome (Molzym), QIAamp DNA Microbiome (Qiagen) and NucleoSpin Soil (Macherey-Nagel) kits. V3V4 16S rRNA libraries were sequenced on Illumina MiSeq. Paired-end 300bp reads were processed into Amplicon Sequence Variants (ASVs) by an in-house pipeline based on DADA2. Sequences were classified by RDP against the EzBioCloud database. Moreover, simulated V3V4 amplicons were extracted from reference genomes by in silico PCRs and classified with the same pipeline.

Results: DNA extraction kits induced systematic but distinct biases [Figure]. Best analytical sensitivity was obtained with the NucleoSpin Soil kit, with 18/20 (90%, in green) bacteria of the mock-community and no contaminants representing more than 1% of the reads. Conversely, less expected bacteria and more contaminants [in red] were recovered by the two host-DNA depleting kits, especially in dilutions below 10^4 bacteria/ml. Six bacteria [30 %] were erroneously classified at the species level, even in absence of wet-lab artifacts, in the in silico simulation. For example, Bacillus cereus was classified as B. anthracis and E. coli as Shigella sonnei. Taxonomic classification improved in 4/6 cases by concatenation of the taxonomic annotation for taxa with identical V3V4 sequences in the EzBioCloud database. Wide range of 16S rRNA copies per genome (2 - 14) and a 3'-end mismatch with Cutibacterium acnes contribute to explain with extraction biases the discrepancies between the observed and expected relative taxa abundances.

Conclusions: These spike-in and in silico experiments based on the ATCC-2002 mock community exemplify the potential impact of DNA extraction and reference databases pre-processing for 16S rRNA metagenomics.

Abstract 5110

**MYCO-TB kit: rapid and efficient digestion and decontamination method for the detection of mycobacteria in extrapulmonary specimens**

Francesco Bisognin*1, Silvia Felici1, Giulia Lombardi1, Caterina Vocale1, Giampaolo Biundo1, Maria Carla Re1, Paola Dal Monte1

1S. Orsola-Malpighi University Hospital, Microbiology Unit - Department of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy

**Background:** Mycobacteria require long incubation time allowing contaminating organisms to overgrow in cultures and preventing their detection. Therefore, processing specimens by digestion and decontamination is necessary before culture.

MYCO-TB is a ready to use sample digesting and decontaminating kit developed by Copan, that requires shorter time for sample processing than other commercial kit. The aim of this study was to compare performance of MYCO-TB with MycoPrep (Becton Dickinson, BD), the latter actually used in our routine flowchart, in terms of detection of mycobacteria and culture contamination on extra-pulmonary samples.

**Materials/methods:** In this prospective study extra-pulmonary samples of a volume greater than 10 ml sent to the microbiology laboratory of the S. Orsola-Malpighi University Hospital (Bologna, Italy) for the detection of mycobacteria have been included. Specimens have been processed both with MYCO-TB and MycoPrep for digestion and decontamination, before culture on solid (Lowenstein-Jensen, with and without PACT antibiotic mix; Biolife) and liquid media (MGIT Bactec 960, BD).

**Results:** Up to date 130 extra-pulmonary samples have been processed: 28.5% cavitary fluid, 22.3% swab, 21.5% urine, 15.4% biopsy, 5.4% purulent exudates, 4.6% lymph-node and 2.3% gastric aspirate. *Mycobacterium tuberculosis* complex (MTBC) was detected in 2 liquid cultures after decontamination with both systems with an average detection time of 23.0±8.0 days for MYCO-TB and 22.2±6.9 days for MycoPrep.

Proportion of contaminated liquid cultures was 3.9% for MYCO-TB and 10.0% for MycoPrep. Contamination of solid media without PACT was 10.8% for MYCO-TB and 6.9% for MycoPrep, while proportion of contaminated LJ PACT was 5.4% with both systems.

**Conclusions:** The MYCO-TB kit has been shown to have a stronger activity than MycoPrep in the digestion and decontamination of extra-pulmonary specimens for the detection of mycobacteria. In addiction ready to use reagents made it possible to reduce and optimize required manual skills and avoid errors during processing. The rapid protocol (5 vs 23 minutes of MycoPrep) and the formulation for single sample of MYCO-TB allow to reduce the time and the risk of contamination of samples, supporting the mycobacteriology laboratory activity.

**Background:** Multidrug-resistant *Escherichia coli* and *Klebsiella pneumoniae* emerged as a relevant cause of bloodstream infections (BSIs) in several countries, including Italy. Prompt initiation of targeted antimicrobial therapy depends on availability of antibiotic susceptibility testing (AST) results. At the end of 2018, EUCAST has validated a method for performing a Rapid AST (RAST) directly from positive blood culture (BC) bottles. The aim of this study was to evaluate the EUCAST RAST method for testing susceptibility to β-lactams, aminoglycosides and ciprofloxacin of *E. coli* and *K. pneumoniae*.

**Materials/methods:** Analysis was prospectively carried out on 101 consecutively positive BCs from nonduplicate patients, in which the presence of *K. pneumonia* or *E. coli* was detected by direct MALDI-TOF mass spectrometry analysis from positive BC broths. RAST was performed as indicated by EUCAST guidelines. Disk diffusion results were compared to reference broth microdilution method. AST results were interpreted according to EUCAST clinical breakpoints. The category agreement (CA) and error rates were calculated as described by the International Organization for Standardization (ISO) guidelines and also considering the new EUCAST definition.

**Results:** The CA values at 4 h, 6 h and 8 h of incubation were 77.2%, 87.7%, 93.5%, respectively using the ISO criteria and 77.5%, 88.0% and 93.8%, respectively according to the modified EUCAST criteria. No very major error was observed, and major error rates were 4.3%, 0.4%, and 0.4% at 4 h, 6 h and 8 h, respectively, using the ISO criteria and 5.1%, 0.9% and 0.9%, respectively, according to the modified EUCAST criteria. Rates of ATU (area of technical uncertainty) were 18.4%, 11.3% and 5.5% at 4 h, 6 h and 8 h, respectively. High ATU rates were observed for gentamicin and amikacin. With the EUCAST RAST method, ESBL and carbapenemase production was correctly detected in all CTX-M (*n*=18), KPC (*n*=7) and OXA-48 (*n*=1) producers, with reading at 4 h and 6 h, respectively.

**Conclusions:** These preliminary data demonstrate the potential feasibility of using RAST to guide antibiotic treatment decisions for patients with life-threatening infections.

Background: Carbapenem-resistant Enterobacteriaceae (CRE) is an urgent challenge in the treatment of bloodstream infections (BSIs). The objective of this study was to investigate the effect of carbapenem resistance on outcomes of bloodstream infections caused by Enterobacteriaceae in China.

Materials/methods: Ten tertiary hospitals located in Guangdong province, China were involved in this study, with a median of 2,040 beds (IQR 1,375-2,850). We performed a retrospective cohort study of 117 patients to explore the association of carbapenem resistance with outcomes of BSI patients. A total of 1,391 Enterobacteriaceae were isolated from the blood of BSI patients. Preliminary species identification was achieved by MALDI-TOF MS and 16s rRNA sequencing. The underlying diseases or comorbid conditions, location before admission, health-care exposures before BSI onset and risk factors source were compared between patients with BSIs due to CRE or carbapenem-susceptible Enterobacteriaceae (CSE). MICs were detected by the broth microdilution method for 16 antimicrobial agents.

Results: Out of the 1,391 isolates, 81 (5.8%) were carbapenem-resistant. Predominant pathogens included K. pneumoniae (n=425; 72 carbapenem-resistant K. pneumoniae [CRKP], 16.9%), and Escherichia coli (n=925; 3 carbapenem-resistant E. coli [CREC], 0.3%). CRE isolates had a more extensive antimicrobial resistance profile than in CSE isolates. All CRE isolates were non-susceptible to cephalosporins. And CRE isolates were most frequently susceptible to colistin (80/81, 99%), followed by tigecycline (67/81, 83%), amikacin (39/81, 48%). A retrospective cohort study of 117 patients found that in-hospital mortality was 35% (22 of 62 patients) for patients with CRE BSI and 16% (9 of 55 patients) for patients with CSE BSI. Exposure to health-care before BSI onset was more frequent among CRE patients than CSE patients. ICU admission within 30 days, transfer from another hospital, central vein catheterisation, and change in antibiotic treatment after the positive culture were independent risk factors determined to be significantly associated with CRE BSI.

Conclusions: Our data demonstrated that the carbapenem resistance was associated with higher mortality of patients with BSI in Guangdong province, China.

Background: Patients in whom blood cultures (BC) are performed are heterogeneous group; while those with positive BC have been extensively studied, data from patients with negative BC are scarce. However, this group of patients might be a suitable population for antimicrobial stewardship (AS) purposes. The NOBACT study aims to characterize this population. The objective of this analysis is to identify the mortality predictors in patients in whom blood cultures are obtained, and specifically in those with negative results.

Materials/methods: The first phase of the NOBACT study is a prospective cohort of randomly selected patients from whom BC were obtained from October 2018 to July 2019 in 3 Spanish University Hospitals. Demographic data, clinical and therapeutic characteristics were studied. The dependent variable was the 30-day mortality after BC. Bivariate and multivariate analysis of factors related to mortality were performed. The adequacy of antimicrobial treatment was defined according to local guideline, considering demographic data, source and severity.

Results: Overall, 622 patients with obtained BC were included; in 123 (19.7%), BC were positive. Mortality was 12% (76 patients). The variables associated with mortality in bivariate analysis are shown in figure 1. By logistic regression, positive blood culture (OR 3.87; 95% CI 1.68-8.95) and inadequate treatment due to lack of appropriate coverage according to local guidelines at day 2 after the blood culture obtainment (OR 3.59; 95% CI 1.49-8.66) were independently associated with mortality. No interactions were relevant. When only patients with negative blood cultures were included, the independent predictors of death were age (OR 1.04; 95% CI 1.01 - 1.07) and inadequate treatment due to lack of appropriate coverage (OR 4.65; 95% CI 1.74-12.40).

Conclusions: These results reinforce the importance of bacteraemia programmes to guarantee adequate treatment in patients with positive blood cultures, and provide novel data suggesting the idea that AS interventions in certain subgroup of patients with negative blood may be considered.

Abstract 5117

Colistin resistance in human Salmonella spp. isolates collected from Italian Enter-Net surveillance during the period 2016-2018

Daniela Fortini¹, Slawomir Owczarek¹, Anna Maria Dionisi¹, Ildo Benedetti¹, Luca Busani¹, Claudia Lucarelli², Laura Villa*¹, Aurora Garcia-Fernandez¹

¹Istituto Superiore di Sanità, Rome, Italy

Abstract third-party references: Istituto Superiore di Sanità

Background: Colistin is used in human to treat multidrug-resistant bacteria infections and in veterinary medicine for therapy and growth promotion in farming animals. Reports of plasmid-mediated colistin resistance mcr genes are increasing worldwide in different bacterial species, including Salmonella. ECDC-EFSA reported a 4.7% colistin resistance in human Salmonella isolates in 2017 in Europe. In this study colistin susceptibility and its molecular mechanisms were investigated in a collection of human Salmonella spp. isolates, provided by the Enter-Net laboratory surveillance network for enteric pathogens in Italy.

Materials/methods: From 2016 to 2018, 330 Salmonella spp isolates were tested for colistin susceptibility by broth microdilution method. Four previously (2009-2015) colistin-resistant Salmonella isolates were included for comparison. Multiplex PCR for detection of mcr-1 to mcr-5 genes was performed. WGS was carried out on 4 susceptible and 8 colistin resistant strains. In silico analysis of MLST, cgMLST, resistant genes, plasmid typing and pMLST were performed. mcr carrying plasmids were completely assembled. Known and unknown hypothetical chromosomal colistin resistance mechanisms were searched.

Results: Colistin resistance (MIC≥4 µg/ml) was reported in 26 out of 330 (7.9%) strains: 23 S. Enteritidis (24.1%), 1 S. Typhimurium (5.5%), 2 S. Typhimurium monophasic variant (3.3%). mcr genes were found in only 3 strains. WGS analysis revealed mcr-1 and mcr-5 in a ST-4 IncHI2 plasmid harbored by a S. Typhimurium monophasic variant strain (2016) and a mcr-1-IncX4 plasmid in a S. Enteritidis and in a S. Typhimurium monophasic variant isolated in 2009 and 2015, respectively. In one S. Napoli isolate a new amino acidic mutation was identified in sapC gene (S241A), involved in colistin resistance.

Conclusions: Salmonella isolates from humans revealed a low proportion of colistin resistance in Italy. S. Enteritidis showed the highest proportion of resistant isolates, probably due to chromosomal gene mutations. The mcr-1 gene was present in our country at least since 2009. A novel IncHI2 plasmid presenting both mcr-1 and mcr-5 genes was detected in this study in a S. Typhimurium monophasic variant. A possible chromosomal colistin resistance mechanism was identified in a S. Napoli isolate.

Abstract 5122

The impact of shortening antibiotic treatment duration on antimicrobial resistance carriage: a modelling study

Yin Mo*1,2,3,4, Mathupane Oonsivilai2,3,4, Cherry Lim2,4, Anastasia Hernandez-Koutoucheva4, Ricardo Leon-Sampredo5, Jiraboon Tosanguan2,4, Rene Niehus6, Ben Cooper2,4

Background: Shortening treatment duration is a key component of antibiotic stewardship interventions. However, the effectiveness of this approach in reducing antimicrobial resistance is uncertain and a clear theoretical rationale for the approach is lacking. We performed a modelling study in order to better understand the circumstances under which reducing antibiotic duration would represent a high impact intervention.

Materials/methods: We constructed three increasingly complex stochastic models to simulate nosocomial transmission and within-host selection of antibiotic-resistant and sensitive bacteria. Antibiotic exposure was assumed to act on within-host processes by modifying bacterial growth and death rates and to act on between-host processes by modifying susceptibility to carriage acquisition and transmission. The primary outcome was the difference in the proportion of carriers of resistant bacteria between the wards receiving long and short antibiotic treatment durations. We performed sensitivity analysis to understand under which circumstances shortening antibiotic duration would reduce the prevalence of resistance carriage. Using parameters appropriate for multidrug-resistant Enterobacteriaceae, we quantified the expected magnitude of the reductions in resistance with shortened antibiotic duration under different scenarios.

Results: The three models reached broadly similar conclusions. Shortening antibiotic duration is most effective at reducing resistance carriage when two conditions hold: individuals not exposed to antibiotics have a minimal probability of acquiring resistant bacteria; and decolonization of resistant bacteria is rapid without antibiotic selective pressure. In addition, longer antibiotic treatment may decrease or increase prevalence of resistance carriers depending on the availability of effective antibiotics targeting particular resistance mechanisms. In low resistance prevalence settings, antibiotic duration has a substantial impact on the prevalence of resistance only when the number of antibiotic prescriptions is already low. In high resistance prevalence and transmission settings, shortening duration rather than the number of prescriptions and narrowing the spectrum of antibiotics contributes more to the reduction of resistance carriage.

Conclusions: Our models suggest that shortening duration is effective at reducing prevalence of resistance carriage only when antibiotics are the key drivers for acquisition and persistent carriage of resistance. The magnitude of reduction in resistance carriage depends on the baseline resistance prevalence, rate of transmission, and the number of antibiotic prescriptions.

Abstract 5123

Characterisation of carbapenemase-producing Enterobacter spp. isolates recovered in a tertiary hospital in Madrid, Spain between 2005 and 2018

Miriam Mateos1, Marta Hernández Garcia*, Rosa Del Campo2, Laura Martínez García1, Desirèe Gijón1, Patricia Ruiz-Garbajosa1, Maria Isabel Morosini Reilly1, Rafael Canton Moreno1
1Servicio de Microbiología. Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Carbapenemase production is constantly increasing in Enterobacterales species. We analyzed the microbiological characteristics and population structure of carbapenemase-producing Enterobacter spp. (Ent-CP) isolates recovered at the Ramón y Cajal University Hospital, Madrid, Spain (2005-2018).

Materials/methods: Bacterial identification was performed (MALDI-TOF MS, Bruker; hsp60 amplification/sequencing). A maximum-likelihood tree was constructed with hsp60 genes (MEGA-6). Antimicrobial susceptibility (microdilution, Microscan, Beckman-Coulter; MIC-strips, Liofilchem) was interpreted using EUCAST 2019 criteria. Carbapenemase production was phenotypically confirmed (KPC/MBL/OXA-48 Confirm kit, Rosco Diagnostica and Hodge modified test). Carbapenemase and ESBL genes were detected (PCR, sequencing). Population structure (PFGE, Bionumerics) and clonal diversity (SDI) were determined. Patient’s clinical charts were reviewed.

Results: Overall, 181 Ent-CP were detected (59.1% colonizations; 39.2% clinical; 1.7% environmental) in medical (61.3%), surgical (20.8%) and ICU (17.3%) areas. Clinical samples were mainly from urinary (n=26) and respiratory tracts (n=12). Median LOS (length of stay) was 31 days (IQR=16-64). 59 cases were considered as hospital acquired and median LOS until Ent-CP detection was 34 days (IQR=13-47), being longer in infected than colonized patients (45 days vs 19 days, p<0.001). Most frequent MALDI-TOF identified species were E. cloacae (n=85) and E. asburiae (n=49). hsp60 gene-sequencing showed a higher diversity: 70 E. hormaechei-clusters III,VI, VII, VIII, 69 E. roggenkampii-IV, 15 E. kobei-II, 9 E. asburiae-I, 3 E. ludwigii-V, 1 E. cloacae subsp. dissolvens-XII. 9 K. aerogenes were also identified. A high clonal diversity (SDI>0.90) was determined except in cluster III (SDI=0.73). VIM-1 (n=133) and OXA-48 (n=34) were the most frequent carbapenemases. KPC-2 (n=9), KPC-3 [n=2], VIM-2 (n=1) and two co-producers (VIM-1+KPC-2, VIM-1+KPC-3) were also present. A fecal carriage increase was observed between 2011-2018 (p<0.001), mainly due to VIM-1 and OXA-48-Ent-CP (p<0.001). OXA-48-E. ludwigii (p=0.006) and KPC-E. kobei (p=0.001) associations were established. ESBL co-production (14.2%) was detected, frequently associated with blaTEM122 (p<0.001), E. roggenkampfi (p<0.001), colonization (p=0.03) and medical areas (p=0.02). Resistance to ertapenem (96.1%), imipenem (37.0%), meropenem (35.0%) and co-resistance to other antimicrobials were observed.

Conclusions: Ent-CP incidence is increasing in our hospital, mainly due to VIM-1 and OXA-48-Ent-CP fecal carriage. Interestingly, hsp60 gene-sequencing showed a higher discriminatory power for Enterobacter spp. identification than MALDI-TOF.

Abstract 5125

**Association between susceptibility to quinolones in Escherichia coli and tetracycline use in the community: analysis with community-specific ARIMA models**

Marie-Anne Vibet¹, Quentin Le Bastard¹, Marcelo Low², Batsheva Gottesman³, José-Maria López-Lozano⁴, Emmanuel Montassier¹, Eric Batard*¹

¹Nantes University, Microbiotas Hosts Antibiotics bacterial Resistances (MiHAR), Nantes, France, ²Clalit Health Services, Health Policy Department, Tel Aviv, Israel, ³Clalit Antibiotic stewardship community program, Tel Aviv, Israel, ⁴Universidad de Murcia, Murcia, Spain

**Background:** Tetracyclines are extensively used in the community. We previously found that tetracycline use was associated with resistance to quinolones in E. coli in a French community (FC), but this association was not described in other communities. Our aim was to assess the association between tetracycline use and E. coli susceptibility to quinolones in 3 distinct communities, by using community-specific models.

**Materials/methods:** Monthly time series of proportions of quinolone susceptible E. coli and uses of quinolones and tetracyclines were obtained from a FC, a Spanish community (SC) and an Israeli community (IC). The study period ranged from 2009 to 2018. The association between antimicrobial use and resistance was tested in each community using multivariate auto-regressive integrated moving average models including time, tetracycline and quinolones uses as explanatory variables, and proportion of susceptible isolates as outcome.

**Results:** Proportions of susceptible isolates in FC, SC and IC were 86%, 60% and 78%, respectively. Median (range) quinolone use in FC, SC and IC were 37 (22 to 54), 74 (43 to 172) and 51 (41 to 60) DDD/1000 inhabitants/month, respectively. Median (range) tetracycline use in FC, SC and IC were 77 (36 to 104), 22 (10 to 36) and 40 (31 to 59) DDD/1000 inhabitants/month, respectively. In the FC, use of quinolones 2 months earlier (estimate [SD], -0.099 [0.031]) and tetracyclines 12 months earlier (estimate [SD], -0.014 [0.005]) were significantly associated with quinolone susceptibility. In the SC, use of quinolones 7 months earlier (estimate [SD], -0.076 [0.022]) and tetracyclines 4 months earlier (estimate [SD], -0.252 [0.093]) were significantly associated with quinolone susceptibility. In the IC, tetracycline use 7 months earlier was significantly associated with quinolone susceptibility (estimate [SD], -0.100 [0.028]) whereas quinolone use was not.

**Conclusions:** In 3 communities that differed greatly by susceptibility to quinolones and antimicrobial use, community-specific ARIMA models showed that there was a significant association between tetracycline use and quinolone susceptibility in E. coli. These results suggest that decreasing tetracycline use in the community may decrease quinolone resistance in community isolates of E. coli.

Preclinical efficacy, pharmacokinetics and safety of CD377, a novel antiviral Fc-conjugate against influenza

Voon Ong1, James Levin1, Allen Borchardt1, Thanh Lam1, Wantong Jiang1, Zhi-Yang Chen1, Quyen-Quyen Do1, Tom Brady1, Alain Nencovich1, Joanne Fortier1, Makia Nakamura1, Karin Amundson1, Jeffrey Locke1, Amanda Almaguer1, Nicholas Dedeic1, Grayson Hough1, Jason N. Cole1, Simon Döhrmann1, Rajvir Grewal1, Elizabeth Abelovski1, James M. Balkovec1, Michael Schlosser1, Ken Bartizal1, Leslie W. Tari*1

1Cidara Therapeutics, San Diego, United States

**Background:** CD377 is a novel antiviral Fc-conjugate (AVC) comprising a potent small-molecule antiviral and the Fc domain of human IgG1. CD377 is long-acting and demonstrates robust efficacy in lethal mouse models of influenza. Studies were conducted to confirm its stability and characterize CD377 pharmacokinetics, safety/tolerability, and efficacy in a mouse influenza prevention model.

**Materials/methods:** CD377 stability was assessed after 0-24 h incubations at 37°C in mouse/human plasma and human liver hepatocytes using MALDI-TOF mass spectrometry. Single-dose pharmacokinetics/tolerability were studied in the mouse (1-100 mg/kg), rat (5-50 mg/kg), and monkey (5-20 mg/kg). Plasma concentrations were measured by a neuraminidase (NA)-capture or Fc-capture with Fc-detection ELISA. In this case, Fc-capture/Fc-detection measured the total concentration of Fc-related species while NA-capture/Fc-detection measured the concentration of intact NA-linked–Fc species. Two-week safety/toxicology was evaluated in monkeys (5-20 mg/kg SC) on days 1 and 8 with necropsy on day 15; clinical signs, chemistries, hematology, cytokines, and histopathology were evaluated. Preventative efficacy was studied in a lethal influenza mouse model using a single dose of CD377 [0.3–3 mg/kg] 28 days prior to intranasal challenge with 3x the LD95 of A/California/07/2009 (H1N1) [3E4 pfu], A/Hong Kong/1/68 (H3N2) [3.6E4 pfu], or B/Malaysia (Victoria lineage) [1E4].

**Results:** CD377 was stable after incubations in plasma and liver hepatocytes. Further, plasma exposures from both Fc-capture/Fc-detection and NA-capture/Fc-detection were comparable, indicating that the molecule remained intact in vivo. In the mouse, rat, and monkey, CD377 t1/2 was 5–10 days. Dose-proportional increases in exposure were observed in each species, notably from 1–100 mg/kg in mouse. High bioavailability (77%) was observed after subcutaneous or intramuscular administration. A single SC dose of 1 mg/kg administered 28 days prior to infection provided 100% protection from death against H1N1 \( P=0.0020 \) (Figure 1) and B \( P=0.0031 \) subtypes. H3N2 required only a 0.3 mg/kg dose for 100% protection \( P=0.0007 \). The 2-week monkey toxicology study showed no adverse effect on bodyweight, clinical chemistry, hematology, coagulation, cytokines, or urinalysis.

**Conclusions:** CD377 was well-tolerated and stable in vitro and in vivo; its extended half-life support its potential as a long-acting, novel AVC for prevention of influenza.

**Figure 1.** Efficacy of CD377 in a 28 Day Prevention Model. A, survival; B, body weight

Abstract 5127

**Automated rapid antimicrobial susceptibility testing from positive blood cultures using Copan WASPLab**

Cees Verduin¹, Sebastiaan Derksen², Jitske Stalpers*¹, Theo Liebregts³, Martijn Nijs¹, Arjan Jansz¹

¹PAMM laboratories, laboratory for medical microbiology, Veldhoven, Netherlands

**Background:** In 2018, EUCAST published recommendations for Rapid AST (RAST) from positive blood culture bottles (BCb) for several species, with direct plating for disk diffusion. Reading of inhibition zones is performed after 4, 6 and 8 hours of incubation with only ±5 minutes of tolerance (*Pseudomonas aeruginosa* only after 6 or 8 hours).

The Copan lab automation can support this workflow: WASP® streaks the plate and dispense the antibiotic disks; WASPLab takes a very high-resolution picture (48Mp) autonomously at stated reading time and an algorithm for the automatic measurement of the inhibition zone supports the plate evaluation.

**Aim of this study is to describe the implementation and validation of the Rapid AST directly from positive BCb manually processed and with the use of automation.**

**Materials/methods:** *Escherichia coli* ATCC25922 and *Staphylococcus aureus* ATCC29213 were used to standardize disk diffusion AST procedure as per EUCAST guideline.

Quality control strains (QC), following EUCAST protocol, and clinical blood culture samples (CBCS) were incubated in bioMérieux BACT/ALERT®. Samples from positive bcbb were inoculated on Mueller Hinton plates using both the manual method and with WASP®. After 4, 6 and 8 hours of incubation, inhibition zones were measured manually with a ruler and automatically read using WASPLab software.

**Results:** All QC was within the ranges for both methods suggesting a good implementation of the RAST as per EUCAST indication.

CBCS for Gram negative bacteria (N=140; not for *P. Aeruginosa*) were 100% readable at 4h, the majority of Gram-positive bacteria (N=60) were readable at 6h or 8 hours. No major/very major errors (S instead of R and vice versa) were found for both methods.

Complete results will be shown at ECCMID.

**Conclusions:** The data collected show an excellent correlation between the manual method and automatic method on WASP and WASPLab. The RAST directly from positive BCb can be easily implemented on the automated platform and has important advantages. These advantages are: 1) standardized reading time points, 2) fully automated workflow, e.g. not hands-on time for technicians 3) High Resolution Images, with automated reading and interpretation 4) Images are always available for evaluation at a later time.

Abstract 5128

**A radiologic score for pulmonary non-tuberculous mycobacterial infection: preliminary results**

Marta Colaneri*1, Andrea Lombardi2, Angela Maria Di Matteo3, Massimiliano Fabbiani3, Sergio Vancheri4, Adele Valentini4, Vincenzina Monzillo5, Raffaele Bruno1

1Fondazione I.R.C.C.S. Policlinico San Matteo, Unit of Infectious Diseases, Pavia, Italy, 2Fondazione I.R.C.C.S. Policlinico San Matteo, Viale Camillo Golgi, Pavia, Province of Pavia, Italy, Unit of Infectious Diseases, Pavia, Italy, 3Azienda Ospedaliera Universitaria Senese, Siena, Italy, 4Fondazione I.R.C.C.S. Policlinico San Matteo, Radiologic Unit, Pavia, Italy, 5Fondazione I.R.C.C.S. Policlinico San Matteo, Microbiologic Unit, Pavia, Italy

**Background:** Nontuberculous mycobacteria (NTM) can cause hard to treat pulmonary infections. These bacteria are ubiquitous in the environment, and it is difficult to differentiate between colonization and infection. Moreover, a tool to assess the lung damage objectively and measure the consequences of treatment is lacking. We aim to develop and validate a reproducible and objective radiologic score and to assess how this score is influenced by treatment.

**Materials/methods:** The score was developed modifying previously published scoring systems on the same pathology. It evaluated: consolidation, solid nodules, ground-glass opacities, bronchiectasis, bronchial wall thickening, atelectasis, bronchial filling and distal bronchiolar filling, pleural alterations and thoracic lymphadenopathies. As preliminary study we retrospectively identified five treated and five untreated adult patients affected by pulmonary NTM infection in our hospital. Their HRCT scans at baseline [time of diagnosis] and follow-up (6-12 months later) were collected and reviewed by four radiologists unaware of patient treatment. The overall scores at baseline and follow-up were matched in order to objectively compare the progress of lung involvement in treated and untreated patients over time.

**Results:** Mean radiological score values at baseline and follow-up were 28.5 (SD 24.5) and 26.1 (SD 25.1), respectively. Overall, the radiological score values did not vary significantly between baseline and follow-up (P=0.6). When stratified according to treatment, the radiological score variation between baseline and follow-up was not different between those treated compared to those who did not receive treatment (p=0.35). Interestingly, when stratified according to the NTM species a difference in the mean of the radiological score values was noted both at baseline and follow-up, although it did not reach significance.

**Conclusions:** The preliminary results show a trend in the difference in the mean of the radiological score values. Further analysis on a larger cohort of patients are needed to validate its capacity to assess changes due to treatment and eventually the presence of a correlation with the species of NTM involved.

![Figure 1](image-url) (A) Differences in radiological score between baseline and follow-up in treated vs untreated patients. (B) Radiological score results according to mycobacterial species at baseline and follow-up. [MAC: *Mycobacterium avium* complex]

Abstract 5129

Optimising pharmacokinetics/pharmacodynamics of β-lactam/β-lactamase inhibitor combinations against high inocula of extended-spectrum β-lactamase-producing bacteria

Vincent Tam*1, Henrietta Abodakpi1, Weiqun Wang1, Kimberly Ledesma1, Paul Merlau1, Katrina Chan1, Rachel Altman1, Amelia Sofjan1, Truc T. Tran2, Michael Nikolaou1

1University of Houston, Houston, United States, 2UTHealth, Houston, United States

Background: Reduced in vitro β-lactam activity against a dense bacterial population is well recognized. It is commonly attributed to the presence of β-lactamase(s) and it is unknown whether the inoculum effect could be diminished by a β-lactamase inhibitor. We evaluated different β-lactam (BL) / β-lactamase inhibitor (BLI) combinations in suppressing a high inoculum of extended-spectrum β-lactamase (ESBL)-producing bacteria.

Materials/methods: Three clinical isolates (2 K. pneumoniae and 1 E. coli) expressing representative ESBL (CTX-M-15 and SHV-12) were examined. The impact of escalating BLI (tazobactam or avibactam) concentrations on BL (piperacillin or ceftazidime) MIC reduction was characterized by an inhibitory sigmoid E_{max} model. The effect of various dosing regimens of BL/BLI combinations was predicted using a novel PK/PD index (%T>MICi), and selected dosing exposures (n=10) were experimentally validated in a hollowfibre infection model over 120 hours. The threshold exposure necessary to suppress a high inoculum of bacteria (approximately 10^8 CFU/ml at baseline) and to prevent regrowth was identified using classification and tree regression analysis.

Results: With escalating BLI concentrations, a reduction in BL MIC was observed and well characterized in all isolates (r² >= 0.93). Regardless of the BL/BLI pairings, regrowth over time could be suppressed using T>MICi >= 73.6%. The exposures to suppress bacterial regrowth were higher than that (55.5%) we reported previously for 10^6 CFU/ml at baseline. These exposures might be attained using the clinical dose of avibactam (0.5 g), but a much higher than the standard dose would be needed for tazobactam (>= 2g).

Conclusions: A dense population of ESBL producing bacteria could be suppressed by an optimized dosing regimen of selected BL/BLI combinations. The reversibility of enzyme inhibition could play an important role in diminishing the inoculum effect. In vivo investigations to validate these findings are warranted.

Presenter email address: vtam@uh.edu
Background: In 2006 the UK introduced 7-valent pneumococcal conjugate vaccine (PCV-7) into the routine childhood immunisation programme which was replaced with the 13-valent pneumococcal conjugate vaccine (PCV-13) in 2010. Since 2003 adults aged 65+ years and all adults at increased risk of pneumococcal infection have been recommended to receive a single dose of the 23-valent pneumococcal polysaccharide vaccine (PPV23). Next generation higher valent PCVs (PCV-15 and PCV-20) are now in advance development and could shortly become available for use in adults.

Materials/methods: Peer reviewed publications (published post 2017) containing data describing the contemporary IPD and pneumococcal pneumonia disease burden in UK adults with insight into epidemiological trends and the individual pneumococcal serotype distribution were identified. The proportion of IPD and pneumococcal pneumonia in adults covered by the serotypes included in PCV-13, PCV-15 and PCV-20 was determined.

Results: Three articles were identified. Overall the incidence of both IPD and pneumococcal pneumonia in UK adults has been rising post 2013/14 though trends vary by individual serotype. Despite herd effects induced by the infant PCV programme the burden of both IPD and pneumococcal pneumonia in adults living in the UK continues to be substantial with no discernible impact of PPV23 at the population level. In 2016/17 the proportion of PCV-13, PCV-15 and PCV-20 type IPD in adults in England and Wales aged 65+ years was 21%, 32% and 63% respectively. Between 2013/14 and 2017/18 the average proportion of PCV-13, PCV-15 and PCV-20 pneumococcal pneumonia identified in English adults aged 16+ years was 35%, 40% and 66% respectively (36%, 39% and 64% in 2017/18).

Conclusions: Vaccinating older UK adults with PCV-13 could address a significant proportion of the current pneumococcal disease burden affecting this population. However, PCV-15 and PCV-20 could provide progressively increased coverage of those pneumococcal serotypes currently causing both IPD and pneumococcal pneumonia in UK adults, with PCV-20 potentially addressing ~65% of the pneumococcal disease burden.

Abstract 5134

Clinical outcomes with the use of telavancin for methicillin-resistant Staphylococcus aureus bacteraemia with minimum inhibitory concentration >1 mcg/mL for vancomycin

Brandon Garcia¹, Jimmy Gonzalez*¹², Yen-Hong Kuo², Saira Chaudhry¹²

¹Ernest Mario School of Pharmacy, Piscataway, United States, ²Hackensack Meridian Health Jersey Shore University Medical Center, Neptune City, United States

Background: The management of methicillin-resistant Staphylococcus aureus (MRSA) bacteraemia is becoming increasingly challenging, as minimum inhibitory concentrations (MICs) to vancomycin and daptomycin are consistently rising. This study aims to evaluate the efficacy and safety of telavancin in the treatment of MRSA bacteraemia with an MIC >1 mcg/mL to vancomycin.

Materials/methods: This study was an Institutional Review Board approved retrospective chart review of patients who received telavancin at an academic, tertiary care medical centre between 2015 January 1 and 2019 May 31. Electronic medical charts were reviewed for: clinical cure; 30- and 60-day relapse; criteria for the Acute Physiology and Chronic Health Evaluation (APACHE) II, the updated Charlson Comorbidity Index (uCCI), and the Pitt Bacteremia scores (PBS); prior antibiotic use; bacteraemia and endocarditis diagnostic criteria; source of infection; microbiological culture clearance; time to discharge; patient mortality; and adverse effects. The primary outcome was clinical cure at discharge, which was defined as the resolution of clinically significant signs and symptoms and clearance of blood cultures.

Results: Thirty-eight charts were identified and eleven met inclusion criteria for this analysis. The average BPS and uCCI scores for included patients were 1.7 and 3, respectively. APACHE II scores were calculated for five patients with an average score of 9.2. Vancomycin or daptomycin were given for an average of 5.4 and 2.6 days, respectively, prior to the initiation of telavancin. The average telavancin dose used for all patients was 7.5 mg/kg. All patients achieved clinical cure at discharge. The average duration of the bacteraemia before and after telavancin therapy was 6.2 and 2.1 days, respectively, with an average treatment length of 37 days; there were no instances of 60-day mortality. Two patients relapsed: one patient after 268 days and another after 467 days. Four patients experienced either significant QTc prolongation or acute renal failure.

Conclusions: The use of telavancin in MRSA bacteraemia demonstrated clinical cure and minimal relapse in our patient population. Telavancin may be a potential treatment option for patients with a vancomycin MIC >1 mcg/mL for MRSA bacteraemia. Large prospective randomised controlled trials are warranted to confirm these observations.

Abstract 5135

**In vitro activity of novel biofilm-disrupting agents against Candida auris and other Candida species**

Jose Vazquez*1, Sushama Wakade2, Elias Manavathu2, Marek Bogacz1, Matthew Myntti3, Stuart Thompson1

1Medical College of Georgia/Augusta University, Augusta, Georgia, United States, 2Medical College of Georgia, Augusta, GA, United States, 3NA, Next Science, Jacksonville Fl, United States

**Background:** *C. auris* is a multi-drug resistant, globally emerging fungal pathogen. In fact, it has been recovered from environmental surfaces and is linked to recalcitrant candidal infections. Chlorhexidine (CHD) appears to be an effective surface disinfectant. Biofilm disrupting agents (BDAs) are novel molecules with a broad spectrum of antibacterial and antifungal activity. BDAs have been used in the treatment of chronic wounds and to sterilize environmental surfaces. The goal of this study was to evaluate BDA technology against *C. auris* and other *Candida* spp.

**Materials/methods:** We evaluated the in vitro efficacy of several BDA agents [topical gel, wound wash solution, and surface disinfectants] vs. CHD against *C. auris* isolates 0381 and 0386, *C. albicans* 90028 and *C. glabrata* 200918 by both agar plate zone inhibition and time kill assays. The efficacy was evaluated based on the magnitude of the inhibition zone and the quantitative reduction of CFU when compared to the control.

**Results:** All 3 BDAs and CHD inhibited *C. auris* growth effectively in a concentration dependent manner. A comparative analysis of the BD agents and CHD against *C. glabrata* and *C. albicans* using time-kill curves not only demonstrated a 99.99% killing at conventional concentrations at 30 minutes, but they also revealed early efficacy with a > 1 log decrease in just 10 min. Regarding *C. auris*, the BDAs demonstrated a 99.99% bactericidal effect within 60 seconds of contact. Furthermore, both CHD and the BD agents showed excellent activity against pregrown *C. auris* cells. BDAs were highly effective against both *C. auris* isolates, whereas CHD was only moderately effective against one of the *C. auris* 0386, suggesting the possible emergence of resistance/tolerance to CHD among different *C. auris* species.

**Conclusions:** All three BD agents and CHD have excellent activity against different *Candida* species, including *C. auris*. In addition, certain isolates of *C. auris* showed increased resistance/tolerance to chlorhexidine, but not to the BD agents. The rapid fungicidal activity of the BD novel agents are extremely valuable in eradicating surface colonization of *Candida* spp, especially *C. auris*. This should be able to decrease the spread of this multi-drug resistant *Candida* spp.

Abstract third-party references: for the DZIF-R-NET Study Group

Background: The emergence of vancomycin-resistant Enterococcus faecium (VREfm) is an important public health problem, creating an urgent need to gather detailed surveillance data. We aimed to investigate the molecular epidemiology of colonizing and infecting VREfm and compare them to vancomycin-susceptible Enterococcus faecium (VSEfm).

Materials/methods: Patients were screened upon hospital admission in 2016 and 2017 for rectal colonization of VREfm at six German tertiary-care university hospitals using chromID VRE (bioMérieux). Isolates were also collected from patients with bloodstream infections (BSI) caused by VREfm and VSEfm. Antimicrobial susceptibility testing for linezolid, teicoplanin and vancomycin was conducted using Vitek2 and Etest. Sequencing libraries were prepared using Nextera XT kit (250bp paired-end) and whole genome sequencing was performed on a MiSeq (Illumina). cgMLST (Ridom® SeqSphere+), 7-loci MLST, and Van-type were determined.

Results: Out of 5846 patients screened, 101 VREfm colonizing isolates were identified (1.7% prevalence), of which 77 harboured the vanB and 22 isolates the vanA operon. Two isolates harboured both vanA and vanB. Sequence type (ST) 117 (n=61) was the predominant clone, forming a large multi-centre complex of closely related isolates dispersed across all study centers. In contrast, ST80 (n=22) formed individual study-center clusters, with no overlapping between centers, and similar clustering patterns were observed for ST78 (n=10) and ST17 (n=3). Examination of the VREfm bloodstream isolates (n=79) revealed a similar pattern; the most prevalent ST was ST117 (n=50), forming a large multi-center complex, followed by ST203 (n=11) and ST80 (n=9) forming smaller clusters. In total, 49 VREfm BSI isolates harboured the vanB, 29 the vanA, and one had both the vanA and vanB operon. Additionally, two colonizing and three BSI isolates were linezolid-non-susceptible. No predominant clone was identified among the 27 VSEfm BSI isolates. The most prevalent STs were ST78 (n=6), ST117 (n=5), ST17 (n=4) and ST80 (n=3) forming small clusters.

Conclusions: These data demonstrate that ST117 was the predominant VREfm clone colonizing patients on admission and among patients with VREfm BSI. ST117 isolates form a large VREfm multi-center cluster expanding in the six study centers. This study provides epidemiological data about VREfm and may contribute to more effective infection control interventions.

**Comparison of methods to evaluate the activity of ceftolozane/tazobactam against clinical isolates of carbapenem-resistant *Pseudomonas aeruginosa* from Chile**

Rodrigo Martinez1,2; Lina María Rivas1,2; Javiera Fuentes1,2; Maria De Los Angeles Spencer1,2; Marusella Lam3; Pamela Rojas4; Victoria Moreno5; Luz María Fuenzalida5; Lorena Porte5; Francisco Silva5; Marcela Cifuentes5; Belgica Barraza5; Béatrice Hervé6; Maria Paz Acuña5; Daniela Ramírez5; Patricia García6,7; Jose Munita*1,2

1Genomics & Resistant Microbes [GeRM], Instituto de Ciencias e Innovación en Medicina, Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Chile, Santiago, Chile, 2Millennium Initiative for Collaborative Research On Bacterial Resistance [MICOBR-R], Iniciativa Científica Milenio, Chile, Santiago, Chile, 3Catholic University Clinical Hospital, Santiago, Chile, 4Hospital Padre Hurtado, San Ramón, Chile, 5Hospital El Salvador, San Miguel, Chile, 6Cícnica Alemana, Vitacura, Chile, 7University of Chile Clinical Hospital, Santiago, Chile, 8Hospital San Borja Arriarán, Santiago, Chile, 9Clínica Las Condes, Las Condes, Chile, 10Florida Hospital Dra. Eloísa Díaz, La Florida, Chile

**Background:** The widespread dissemination of carbapenem-resistant *P. aeruginosa* (CR-PAE) is considered a major global public health threat. C/T is a recently approved combination of a novel cephalosporin (ceftolozane) and tazobactam (a β-lactamase inhibitor). The activity of C/T against CR-PAE remains high. However, recent reports have raised concerns about susceptibility testing methods to evaluate the in-vitro activity of C/T, due to discrepancies between them. Therefore, we aimed to evaluate the activity of C/T against Chilean clinical isolates of PAE using different susceptibility methods.

**Materials/methods:** We analyzed 66 PAE isolates (50 CR and 16 carbapenem-susceptible [CS]) collected during 2017 from 5 tertiary care institutions in Santiago, Chile. All isolates exhibited a negative Blue-Carba result. C/T susceptibility was performed by broth microdilution (BMD), E-test (Biomerieux), MIC test strip (Liofilchem), and disk diffusion ([DD], Hardy Diagnostics, 30ug discs), following CLSI-2019 recommendations. All tests were performed using the same inoculum and ATCC® 27853 was used as a reference. Results were compared to the reference method (BMD). Essential and categorical agreement (EA, CA), very major, major and minor errors (VME, ME, MiE) were determined.

**Results:** The BMD MIC₅₀/₉₀ for CR and CS-PAE were 1/16, and 0.25/1 μg/mL, respectively. All CS-PAE isolates were susceptible to C/T. For CR-PAE, 40/50 (80%) isolates were susceptible, 1/50 (2%) intermediate and 9/50 (18%) resistant to C/T. All C/T-resistant isolates were multidrug-resistant [7 of them extremely-drug-resistant] and 3/9 were found to harbor a carbapenemase by qPCR [1 *bla*KPC, 1 *bla*VIM, and 1 *bla*NDM]. For CR-PAE, the MIC₅₀/₉₀ with E-test, and MIC strips were 1.5/24 and 2/8 μg/mL, respectively. Susceptibility to C/T reached 88%, 78%, and 78% for E-test, MIC strips, and DD, respectively. The EA between BMD and both E-test and MIC test was 82%. The CA for E-test, MIC test, and DD was 92%, 88%, and 90%, respectively. The VME/MiE for E-test, MIC strip and DD were 33%/2%, 22%/6%, and 11%/6%, respectively. No ME were found.

**Conclusions:** In this multicenter study, C/T was highly active against clinical isolates of CR-PAE. All evaluated methods exhibited a good CA, however, the observed rates of VME were worrisomely high.

Abstract 5138

Incidence and predictors of *Chlamydia trachomatis*, *Ureaplasma urealyticum*, *Mycoplasma hominis* and *Mycoplasma genitalium* in patients with sterile pyuria

Anivita Aggarwal*, Benu Dhawan¹, Naveet Wig¹, Naval Vikram¹, Manish Soneja¹, Rama Chaudhry¹, Arti Kapil¹

¹All India Institute Of Medical Sciences, New Delhi, India

**Background:** Sterile pyuria has various infectious and non-infectious causes, posing a major diagnostic challenge and warrants detailed evaluation. Genital mycoplasmas usually remain asymptomatic. These are not detected by routine microbiological diagnosis, hence are often left undetected in most resource limited laboratories in India and left untreated.

**Materials/methods:** A prospective observational study - Oct 2017 to August 2019, adults admitted to Medicine wards were screened for sterile pyuria, detected within 24 hours of admission, irrespective of their primary presentation. Sterile pyuria was defined as urine microscopy showing > 10 WBC/HPF and no growth on blood and/or MacConkey agar. Polymerase Chain Reaction (PCR), for the detection of *C. trachomatis* and genital mycoplasmas, was performed on the urine samples as described (fig 1). Culture was also performed for *M. hominis*, and Ureaplasm spp. Patients were evaluated for other causes of sterile pyuria. They were treated with doxycycline and azithromycin and followed up.

**Results:** Occurrence of sterile pyuria in our hospital was found to be 72 (17.5%) out of 410 patients. Out of these, *C. trachomatis* and genital mycoplasmas were tested positive in 22/72 (30.5%) (*M. hominis* was 5 (6.9%), *U. urealyticum* 12 (16.7%) and *C. trachomatis* 13 (18.1%)). No patient was tested positive for *M. genitalium* or genitourinary tuberculosis. Risk factors such as chronic kidney disease (*p* = 0.008) and past history of urinary tract infection (*p* = 0.022) were significantly associated with these patients [22/72]. Due to underlying illness 4/22 patients expired. After treatment with doxycycline 12/22 (54.5%) and azithromycin 6/22 (27.2%), all patients showed complete resolution of pyuria on repeat testing at 2 weeks.

**Conclusions:** This is the first study from India to test occurrence and predictors of atypical organisms in sterile pyuria (17.5%) as compared to [1-10%] found in others. *C. Trachomatis* and genital mycoplasmas are important causes of sterile pyuria, with predisposing risk factors being CKD or history of UTI, warranting screening and evaluation. Contrary to the previous studies, genitourinary tuberculosis was not a cause.

Background: Immunosuppression, male, age >50 and chronic liver disease are risk factors for Hepatitis E Virus (HEV) disease. In Belgium, diagnosis of HEV is centralized at Sciensano. We aimed at identifying risk factors and clinical outcomes associated with HEV genotype (gt) 3 subtypes in a nationwide cohort of HEV patients.

Materials/methods: Demographic, clinical and biochemical parameters of HEV infections between 2010-2018 were collected. Serum HEV – IgM, – IgG and HEV RNA were determined by ELISA and RT qPCR. HEV was subtyped by Sanger sequencing of an ORF2 fragment. Odds ratios (OR), risk ratios (RR) and 95% confidence intervals (95% CI) were calculated using STATA.

Results: Among 300 HEV cases with clinical data, the median age was 57 years and 69% were males. Viremia was detected in 211 patients, with a genotype identified in 177. HEV gt3 infections predominate [93% [165/177]] with subtypes 3c [38% [67/177]] and 3f [44% [78/177]] almost equally represented. The percent of immunocompromised patients [30% vs 16%, ORa=2.2 [1.0-4.7] p=0.045] was higher among patients with a clade-3c [achi] virus compared to a clade-3f [elg], while a similar tendency was observed for pre-existing liver cirrhosis [9.9% vs 3.4%, ORa=3.4 [0.8-12.5]]. Among patients with a clade-3f virus, higher peak values of ALT [mean of 2199 vs 1528 U/L; p=0.005] and bilirubin [mean of 8.6 vs 4.1 mg/dl; p=0.001] were identified, compared to patients with clade-3c virus. In addition, the risk of hospitalization for patients with a clade-3f virus was almost twice that of patients with clade-3c virus [36% for 3c; 61% for 3f; RR=1.7 [1.2-2.4] p=0.003]. There was a non-significant tendency towards higher mortality for clade-3f infections [1.4% vs 4.8%; RR=3.4 [0.4-30]], but no differences in intensive care unit admissions [5.7%], hospitalization durations (median of 4.0 weeks) or in chronicity [18% vs 14%, RR=0.8 [0.4-2.0]].

Conclusions: A similar number of HEV-gt3c and -gt3f infections have been diagnosed in Belgium. Despite more pre-existing comorbidity among patients with HEV-gt3c, patients with HEV-gt3f are associated with higher risks for hospitalization and high liver enzyme values. Our nationwide analysis is the first to identify a correlation between HEV-gt3 subtypes and these clinical outcomes.

Abstract 5142

**Intact bacteria species-specific lipid profiling using the MALDI Biotyper Sirius can identify mycobacteria in one step**

Broda Agnieszka¹, Ximena Gonzalo¹, Markus Kostrzewa², Francis Drobniewski¹, Gerald Larrouy-Maumus*¹

¹Imperial College, London, United Kingdom, ²Bruker Daltonik GmbH, Bremen, Germany

**Background:** Over the last decades, MALDI mass spectrometry has become the workhorse of clinical laboratories for Gram-Negative and Gram-positive bacterial diagnostics. For mycobacteria, an adapted and validated MALDI methodology, based on cytosolic protein profiling, has been established. Although this method is able to identify and differentiate a very broad spectrum of mycobacteria, a number of limits in species- and intra-species differentiation has been observed. Identification without culture is largely being performed by DNA-based methodologies which are relatively expensive and limited in species coverage. Here, we propose another alternative based on species-specific lipid profiling of heat inactivated bacteria, with very limited preparation using routine MALDI Biotyper Sirius.

**Materials/methods:** A collection of 27 reference strains from ATCC and ECDC were used to evaluate the use of species-specific lipids as discrimination markers. The method we have developed is fast (<5 mins after heat inactivation) and uses MALDI-TOF MS combined with a suitable matrix (super-2,5-dihydroxybenzoic acid solubilized in ethanol 70%) to analyze lipids of heat-inactivated mycobacteria. Cultured mycobacteria are heat-inactivated and loaded directly onto the MALDI target followed by addition of the matrix. Acquisition of the data has been done in both positive and negative ion mode using a MALDI Biotyper Sirius system (Bruker Daltonik).

**Results:** We have been able to build a database and the following glycolipid family were identified: i) glycopeptodilipids and phenolglycolipids, the immunoreactive glycolipids species-specific ii) phosphatidyl-myo-inositol mannosides as ligand of TLR2 receptors and antigens of CD1 restricted αβT cells. Thank to use of species-specific lipids, we were able to unlock key challenges associated with mycobacterial ID such as one-step samples preparation as well as discrimination within the M. abscessus and Tuberculosis complex, in the positive and negative ion mode, which was not currently possible.

**Conclusions:** Thanks to its speed of execution, intact bacterial lipid profiling provide a unique route for mycobacterial identification using the MALDI Biotyper Sirius. It may complement the broad identification capabilities of the protein-based mycobacteria identification by MALDI-TOF MS, enabling the resolution of closely related species complexes. Further, the high sensitivity of the method might lead to a route to direct sample analysis.

**Presenter email address:** g.larrouy-maumus@imperial.ac.uk
Background: resistance to antibiotics can change over time due to consumption and adequacy of its use, among other factors. Cumulative antimicrobial tests data have great epidemiological and clinical impact, since they show trends over time and guide the selection of empirical treatment. Antimicrobial resistance surveillance is the first step, together with days of treatment determination, to implement a paediatric antibiotic stewardship program in Catalonia. Our objectives were to analyse the susceptibility of the main microorganisms causing paediatric infections in an area covered by 13 health-care centers and to compare that to the global susceptibility testing results (>95% from adults).

Materials/methods: susceptibility data refer to isolates identified from clinical samples collected from children under 18y, including neonates, during 2018. Isolates reported as intermediate or resistant were classified as resistant. All centers used EUCAST breakpoints. Different microorganisms/antibiotics were included depending on their origin (hospital or community). Resistance percentages for specific pathogens-antibiotics were calculated.

Results: the percentage of extensively drug-resistant Pseudomonas aeruginosa (XDR) was 5.8% in children versus 10.1% in adults. Escherichia coli and Klebsiella pneumoniae results are shown in the table. No isolates of vancomycin resistant Enterococcus spp. were detected. There was no difference in the MRSA percentage between hospital and community (10%) but it was lower than in adults (24.1%). Penicillin non-susceptible Streptococcus pneumoniae percentage was 19.2% in children vs 20.2% in adults and macrolide resistance was 19.7% vs 23.1% respectively. Streptococcus pyogenes macrolide and clindamycin resistance was 5.7% and 3.5% respectively in children and 7.7% and 5.4% in adults.

Pathogen/antibiotic | Escherichia coli (n=2999) | Klebsiella pneumoniae (n=461) |

Conclusions: percentages of multiresistant ESBL-E.coli, ESBL/CP-K.pneumoniae and XDR-Pseudomonas were lower in Pediatrics compared to adults and in the community compared to the hospital setting, in the case of ESBL-E. coli. For Gram-positive bacteria, lower percentages of resistance were detected in children compared to adults. Surveillance of antimicrobial resistance is essential to guide infection control and antimicrobial stewardship objectives.

Abstract 5145

**Mechanism of ceftazidime-avibactam resistance in carbapenem-resistant Escherichia coli isolated in the Arabian Peninsula**

Agnes M. Sonnevend1*, Akela Ahmed Ghazawi1, Vincenzo Di Pilato2, Alberto Antonelli3, Gian M. Rossolini3, Tibor Pal2

1University of Pécs Faculty of Medicine, Pécs, Hungary, 2United Arab Emirates University, Al Ain, United Arab Emirates, 3University of Florence, Florence, Italy

**Background:** The aim of the study was to reveal the molecular mechanism of ceftazidime-avibactam non-susceptibility in four carbapenem resistant carbapenemase non-producer Escherichia coli (CREC) isolated in four different hospitals in the Arabian Peninsula.

**Materials/methods:** Whole genome sequencing reads of isolates obtained using Illumina MiSeq (250 bp paired-end) were assembled using SPAdes and annotated by RAST. ResFinder was used to investigate antibiotic resistance genes. Clonality was assessed by cgMLST using Ridom SeqShere+. MIC of ertapenem (ERT), ceftazidime (CAZ), ceftazidime-avibactam (CAZ-AVI) alone and in the presence of phenylalanylarginine β-naphthylamide (PAβN) efflux inhibitor was determined by broth microdilution.

**Results:** The molecular features and susceptibility of the four CREC are shown in the Table.

The isolates were non-clonal, even the two E. coli ST410 exhibited 106 differences over 2513 alleles by cgMLST. All isolates possessed an insertional mutation in the *ftsI* gene leading to a four amino-acid insertion into their PBP3, although the amino acids inserted were not identical. The isolates had either disrupted ompC, or ompC20 variant previously proven to lead to elevated beta-lactam MIC. PAβN efflux inhibitor lowered the MIC of CAZ-AVI two to eight-fold in all four isolates, suggesting that an efflux mechanism also played a role in the CAZ-AVI resistance.

**Conclusions:** In four, clonally unrelated carbapenem resistant E. coli isolated in the Arabian Peninsula the combination of three resistance mechanisms, including PBP3 modification by insertional mutations previously associated with elevated aztreonam-avibactam MIC, loss or modification of ompC and ompF porins and efflux mechanism, resulted in ceftazidime-avibactam resistance prior to the introduction of avibactam combinations into clinical practice in the region.

Perinatal hormones favor CC17 Group B Streptococcus intestinal translocation through M cells and hypervirulence in neonates

Constantin Hays¹, Gérald Touak², Abdelouhab Bouaboud², Agnès Fouet², Julie Guignot², Claire Poyart¹, Asmaa Tazi*¹

¹University of Paris / Cochin Hospital, Paris, France, ²University of Paris, Cochin Institute, Paris, France

Abstract 5146

**Background:** Group B Streptococcus (GBS) is the leading cause of invasive bacterial neonatal infections. Late-onset diseases (LOD) occur between 7 and 89 days of life and are largely due to the CC17 GBS hypervirulent clone. Remarkably, this clone is less responsible for Early Onset Diseases (EOD, 0 to 7 days of life) and largely underrepresented in GBS adult diseases, implying that specific host factors might be involved in CC17 GBS invasiveness in > 7 day-old neonates.

**Materials/methods:** We studied the impact of estradiol (E2) and progesterone (P4), which impregnate the fetus during pregnancy, on GBS neonatal infection. One CC17 and one non-CC17 representative GBS isolates, both of capsular serotype III and responsible for neonatal disease were studied in cellular and mouse models of hormonal exposure corresponding to concentrations found at birth (E2-P4 C0) and over 7 days old (E2-P4 C7).

**Results:** We show that E2-P4 C7 concentrations specifically favor CC17 GBS meningitis following mice oral infection. CC17 GBS crosses the intestinal barrier through M cells. This process is mediated by the CC17 GBS-specific surface protein Srr2 and is enhanced by E2-P4 C7 concentrations which promote M cell differentiation, CC17 GBS intestinal translocation and CC17 GBS invasiveness.

**Conclusions:** Our findings provide an explanation for CC17 GBS responsibility in LOD in link with neonatal gastrointestinal tract maturation and hormonal imprint.

Abstract 5147

eHealth use in tuberculosis: results from a systematic review and focus group interviews in six countries worldwide

Margineanu Ioana*1, Onno W. Akkerman1; Christina Louka1; Ymkje Stienstra1; Jan W. C. Alffenaar1,2

1University Medical Center Groningen, Rijksuniversiteit Groningen, Groningen, Netherlands, 2The University of Sydney, Faculty of Medicine and Health, Camperdown, Australia

Abstract third-party references: GGD Groningen, the Netherlands, Pronkewail Project, Horizon 2020, Marie Skłodowska Curie Action, Beatricoord Clinic, UMCG, Groningen, the Netherlands, Sotiria Thoracic Diseases Hospital of Athens, Greece, Iasi Pulmonology Hospital, Romania, Presbyterian Hospital Agogo, Ghana, Fundación Instituto Carabobeño para la Salud, Venezuela, Central General Hospital Dr. Sardjito, Indonesia

Background: With the constant expansion of internet and mobile technologies, new opportunities arise for digitally delivering healthcare services, namely eHealth. Tuberculosis (TB) is an attractive field for eHealth implementation. We aimed to examine the use and perceptions of eHealth by performing a systematic review and interviews performed in six countries amongst TB experts and patients.

Materials/methods: The systematic review protocol was registered on PROSPERO (CRD42018115440) and adhered to PRISMA guidelines. The WHO Digital health guideline was used as a framework to present results. The focus group interviews were performed in Romania, the Netherlands, Greece, Ghana, Indonesia and Venezuela.

Results: Out of the 3154 screened studies, 85 were included. Most interventions focused on diagnosis (n=44) and treatment (n=38) and least contained an educational component (n=5). The likelihood of a patient to be diagnosed was higher with eHealth (95% CI, OR 2.80 [1.60, 4.86], I²=91%) and eHealth patients tended to be more adherent (95% CI, OR 1.53, [1.14-2.05], I²=74%). eHealth users found interventions useful (483/529, 91.3%). eHealth saved 9.56 - 14321 euros per patient (664 patients) and there were zero privacy breaches for 631 patients. Most frequent challenge was hardware-related (24/246, 17% users).

The most frequent theme in the focus group interviews was how eHealth could improve education in TB (144/911, 15% of quotes), followed by the potential of eHealth to streamline communication (67/911, 7% of all quotes). Participants in any of these six countries think eHealth would be a positive addition to TB management, provided that the app is user-friendly, translated, and free. Groups in the low-income countries reported being concerned about needing training and access to hardware.

Conclusions: A wide array of eHealth solutions has been successfully implemented. Our study suggests the main gap between literature and expectation is the TB health care workers and patients’ opinion that eHealth’s maximum potential lies in delivery of information and education. Literature as well as potential users expect eHealth to be beneficial.

Doctor I’ve been bitten: a smart phone application to identify arthropod bites and stings
Alex Kew*1,2, Vincent Smith2
1Imperial College, London, United Kingdom, 2Natural History Museum, London, United Kingdom

Abstract third-party references: Natural history museum London, Imperial College London, Hospital For Tropical diseases London

Background: Arthropod related injury including bites, stings and allergic reactions to body parts are extremely common in the UK and indeed most parts of Europe. Stings in Europe are one of the commonest causes of severe allergic reaction and each year the number of large scale biting epidemics by flies, mosquitoes and lice, leading to multiple cases of infection, are increasing. Alongside this, dramatic ongoing changes in our climate mean that species carrying diseases that used to be solely associated with travelling to the tropics are now being found here on European shores. Many of these arthropod species are not well recognised and this can often lead to poor identification, misinformation and incorrect treatment.

Materials/methods: To combat this, our group consisting of London Natural History Museum and Imperial College University researchers and I created an identification smart phone application to help firstly identify UK arthropods that have caused injury and secondly provide information on those arthropods regarding the injuries they commonly cause and first line treatments. Arthropod recognition is completed using matrix key identification plus visual images, which then links to factsheet information for the commonest 51 species that harm people in the UK.

Results: The smart phone application contains an alphabetical list of the 51 species with each linked to the corresponding fact sheet, the aforementioned matrix key search function that narrows down possible arthropod culprits as questions are answered and finally treatment information is also provided in an easy to access fact sheet format for each specific injury inflicted. The app is designed in a modular format so data from other European countries can be added and used to provide advice for their arthropods specifically.

Conclusions: Lessons from this study emphasize the compromise between science and usability that is needed to create a well-functioning app and highlight the expanding scope that technology like this can provide for further health related animal and plant group identification beyond just simply arthropods.

Cluster of invasive Mycobacterium chimaera infection in a single cardiac surgery unit: clinical features and management
Nicoletta Riva*, Laura Cavazzuti†, Letizia Pescarolo†, Giulia Marini†, Giacomo Magnani†, Marco Massari†

1Arcispedale S. Maria Nuova-IRCCS, Infectious Disease Unit, Reggio Emilia, Italy, 2Arcispedale S. Maria Nuova-IRCCS, Infection Control Unit, Reggio Emilia, Italy

Background: In the last years a growing cases of disseminated infections due to Mycobacterium chimaera has been seen in patients undergoing open cardio-thoracic surgery with the use of Heather-Cooler Units (HCUs) for extracorporeal circulation. Airborne transmission is the source of infection due to the aerosolization of water containing M. chimaera from the HCUs. Invasive M. chimaera infection can lead to systemic or local manifestation, the latency is long and the outcome is poor.

Materials/methods: In our study we reported 7 cases of invasive M. chimaera infection observed in the Reggio Emilia Hospital. We followed ECDC criteria to identify probable or confirmed cases in patients having undergone cardiac surgery with implantation of prosthesis or devices in local cardiac surgery between 2010 and 2017.

Results: The incidence of invasive M. chimaera infection in the period 2010-2017 was 0.35%. Patients were all males with a median age of 57-years-old. All our cases had devices or prosthesis that increased the risk of disseminated form of the disease. The median period of latency between cardiac surgery and onset of symptoms was 26 months with a range of 11-45 months. All patients have shown signs of disseminated disease affecting more organs associated with: prosthetic valve endocarditis (n=3), prosthetic vascular graft infection (n=1), spondylodiscitis (n=1), chorioretinitis (n=2). Symptoms and signs reported were fever, weight loss, asthenia and splenomegaly. Laboratory test alterations were pancytopenia, renal impairment, hepatitis and liver cholestasis. In 5 patients the positivity of blood cultures was immediately attributed to M. chimaera, in one patient to MAC and in another patient to M. intracellulare, only subsequently typed as M. chimaera. Genotypic drug resistance both for macrolide and aminoglycoside was negative. In 6 patients histopathology demonstrated non-necrotizing granulomas in examined tissues. Anti-mycobacterial multidrug regimen included a macrolide, a rifamycin, ethambutol plus/minus amikacin, levofloxacin or moxifloxacin. Two patients underwent a cardiac re-operation. Mortality was 43%.

Conclusions: This study describes a local outbreak in a single cardiac surgery unit. M. chimaera infection should be strongly suspected in patients with a history of cardiac surgery who develop compatible and unexplained manifestations and clinicians should exclude both disseminated and localized infections.

Systematic review: transmission inference using single nucleotide polymorphism [SNP] differences between isolates of ESBL and CR-Enterobacteriaceae. Can a SNP cutoff be defined?

Alainna Jamal*, Antoine Corbeil1, Lubna Farooqi2, Zoe Zhong2, Elizabeth Uleryk2, Allison Mcgeer1

1University of Toronto / Sinai Health System, Toronto, Canada, 2Sinai Health System, Toronto, Canada

Background: Whole-genome sequencing and phylogenetic analyses are increasingly used to investigate transmission. However, the number of SNP differences that defines a transmission event for Enterobacteriaceae is unclear. This systematic review summarizes SNP differences reported between ESBL-producing and carbapenem-resistant (CR)-Enterobacteriaceae isolates in transmission clusters.

Materials/methods: MEDLINE, MEDLINE In-Process, MEDLINE Epub Ahead of Print, and Embase (OvidSP) databases (Jan. 1995-Jul. 2019) were searched using subject headings and textword terms for whole-genome sequencing and beta-lactam-resistant Enterobacteriaceae. 7,618 reference were retrieved; 1,465 duplicates were removed. 6,153 unique references were reviewed against inclusion criteria (epidemiological data and SNPs used in transmission inference).

Results: 525 titles and 161 abstracts met inclusion criteria. Data have been extracted from 43 full-texts reporting 69 transmission clusters. Table shows cluster characteristics. Among 62 clusters with person-person transmission, median (IQR) number of cases per cluster was 4 (2-9). Among 7 clusters with only environment-person transmission, number of cases linked to the environment per cluster was 1 (5), 2 (1), and 3 (1). Between isolates of cases deemed to be linked, the median (IQR,range) minimum SNP difference and median (IQR,range) maximum SNP difference was: 1 (0-4,0-94) to 11 (4-22,1-131) for K. pneumoniae, 0 (0-3,0-7) to 6 (3-12,0-28) for E. coli, and 0 (0-2,0-19) to 7 (3-11,0-142) for E. cloacae. In 24 clusters, investigators had a pre-defined cutoff for SNP differences indicating possible transmission; organisms and cutoffs were E. coli (≤10, ≤12, ≤58), K. pneumoniae (≤12, 151, <300), and E. cloacae (<10, <15).

Conclusions: In reported clusters of E. coli, K. pneumoniae, and E. cloacae colonization/infection, SNP differences were <12 and 142 at most, with similar distributions between different species. These data may inform guidelines for interpreting relatedness in outbreak investigations.

Investigating a cluster of community-acquired methicillin-resistant *Staphylococcus aureus* infections in a school in Eastern Switzerland

Frederike Waldeck*, Nolte Oliver†, Susanne Manser‡, Danuta Reinholz§, Angela Walt‖, Matthias Schlegel‡, Salome Seiffert‡, Christian Kahlert†,‡

†Cantonal Hospital St. Gallen, Department of infectious diseases and hospital epidemiology, St. Gallen, Switzerland, ‡Centre for Laboratory Medicine, Division of Human Microbiology, St. Gallen, Switzerland, §Children’s Hospital of Eastern Switzerland, Department of infectious diseases and hospital epidemiology, St. Gallen, Switzerland, ‖Department of Health, Office of the Chief Medical Officer of Canton St. Gallen, Division of Public Health, St. Gallen, Switzerland, ‡Department of Health, Office of school medicine, Division of Public Health, St. Gallen, Switzerland

**Background:** A cluster of infections with community acquired Methicillin-resistant *Staphylococcus aureus* (CA-MRSA), positive for Panton-Valentin leucocidin and characterized by efflux-mediated MLSB-resistance, was detected at a paediatric tertiary hospital in Switzerland since 2018. Outbreak investigation was started with the aim of identifying the source of the cluster and preventing further transmissions.

**Materials/methods:** Confirmed cases were defined as an infection with CA-MRSA of identical sequence type (ST) as revealed by whole genome sequencing (WGS) with ≤5 single nucleotide polymorphisms (SNP) within core genome multilocus sequence type. Probable cases were defined as infection with CA-MRSA without confirmation by WGS but with identical antibiotic susceptibility pattern (macrolide resistant/ clindamycin susceptible). Risk factors were evaluated by a questionnaire for confirmed and probable cases. Since most cases were children, questions regarding care facilities, schooling, activities and pets were included.

**Results:** The clustering involved 27 cases (22 confirmed cases with ST5 and 5 probable cases) of which 24 were children <18 years (median age 10.5 years [interquartile range 9 – 12 years]), the remainder being 2 teachers and 1 father of a child. 37% of cases were females. Clinical presentation of MRSA infection was skin or tissue infection in >90% of cases and septic arthritis with bacteraemia in one case. The return of the questionnaires was 63%. 74% of cases were linked to the school of which six cases attended the local child care facility (p=0.94). No link to the school could be evaluated in seven cases (six attended other schools in the same city, one did an apprenticeship). None of the activities clustered in relation to recreational or school activities, animal contact or exposure to the health care system.

**Conclusions:** This MRSA cluster was associated with one school. We hypothesize that transmission occurred during school activities and that transmissions are ongoing. Seven secondary cases were observed with probable transmission out of the school. A cross-sectional study with swabing and a modified questionnaire is already scheduled to evaluate the prevalence of colonisation and infection in the affected school, to confirm the hypothesis, identify the possible route of transmission and to define measures against further transmissions.

Innovative antibacterial agents eradicate bacteria including persisters within mature biofilms

Julia Wubbolts*1, Henk Scheper1, Joanne Verhagen1, Adriette De Visser1, Maya Merabishvili2, Jean-Paul Pirnay2, Mark G.J. De Boer1, Peter H. Nibbering2

1Leiden University Medical Center, Department of Infectious Diseases, Leiden, Netherlands, 2Queen Astrid Military Hospital, Laboratory for Molecular and Cellular Technology, Burn Wound Center, Brussels, Belgium

Background: Prosthetic joint infection (PJI), a severe complication of joint replacement surgery, is difficult to treat due to biofilm- and persister formation on the surface of the implanted device and in the peri-implant tissue. As antibiotics often fail to clear the bacteria within biofilms, innovative antibacterial strategies are needed. Therefore, we compared the efficacy of the synthetic antimicrobial and antibiofilm peptide 148 (SAAP-148), bacteriophage ISP, and antibiotics on methicillin-resistant Staphylococcus aureus (MRSA) in mature biofilms in vitro.

Materials/methods: MRSA biofilms were grown for seven days on plastic surfaces and thereafter exposed to (I) high dose (10x MBC) of antibiotics (rifampicin and ciprofloxacin), (II) SAAP-148, (III) bacteriophage ISP, and (IV) the combination of antibiotics and bacteriophage ISP, daily for three days [Figure 1A]. At 24 hours after each daily application of these agents, the numbers of surviving bacteria were determined microbiologically. In addition, to assess the efficacy of these antibacterial agents on biofilms enriched in persisters, mature biofilms were first exposed to antibiotics for three days and then exposed to (I) SAAP-148, (II) bacteriophage ISP, (III) a combination of antibiotics and bacteriophage ISP or (IV) antibiotics, as a control [Figure 1B].

Results: SAAP-148 dose-dependently eradicated bacteria within mature biofilms on plastic surfaces. In contrast, bacteriophage ISP up to 7x10^8 PFU/ml did not efficiently reduce bacterial counts within mature biofilms. As expected, the antibiotics reduced the bacterial counts by 3-logs, but did not eradicate the bacteria in mature biofilms. Interestingly, the combination of bacteriophage (7x10^8 PFU/ml) and antibiotics almost completely eradicated the bacteria residing in biofilms within 24 hours [Figure 1A]. SAAP-148 as well as the combination of bacteriophage and antibiotics completely eradicated bacteria residing in 3 days antibiotics-exposed mature biofilms, while antibiotics alone were unable to further reduce bacterial counts in biofilms [Figure 1B]. Interestingly, bacteriophage ISP rapidly (within 1 day) and dose-dependently reduced the number of bacteria within the antibiotics-exposed mature biofilms.

Conclusions: SAAP-148 or bacteriophage ISP in combination with antibiotics are promising antimicrobial strategies in the battle against biofilm-associated infections like prosthetic joint infections.

Abstract 5159

Healthcare-associated infections, antibiotic use and resistance in Swiss long-term care facilities: a multi-centre point prevalence study

Delphine Hequet1, Salome Seiffert1, Simone Kessler1, Gabriela Rettenmund1, Eva Lemmenmeier1, Nolte Oliver1, Adrian Egli2, Helena Seth-Smith4, Thomas Münzer3, Matthias Schlegel2, Christiane Petignat1, Philipp Patrick Kohler*3

1Lausanne, Lausanne, Switzerland, 2Zentrum für Labormedizin, St. Gallen, Switzerland, 3Kantonsspital St.Gallen, St. Gallen, Switzerland, 4Basel, Basel, Switzerland, 5Geriatrische Klinik St.Gallen AG, St. Gallen, Switzerland

Abstract third-party references: Swiss National Science Foundation, Federal Office of Public Health

Background: The burden of healthcare-associated infections (HAI) and antimicrobial resistance in Swiss long-term care facilities (LTFC) is unknown. We assessed the prevalence of HAI, antibiotic use and resistant pathogens among Swiss LTFC residents.

Materials/methods: From August to October 2019, we performed a point-prevalence study in LTFCs in Eastern and Western Switzerland according to the “Healthcare-associated infections in Long-Term Care Facilities” (HALT) protocol. LTFC residents were screened for HAI and current antibiotic treatment. Characteristics of residents (age, sex, wounds, dementia, medical devices, use of proton-pump-inhibitors [PPI]) and institutions (geographic region) were registered. In addition, consenting residents underwent rectal screening for extended-spectrum β-lactamase (ESBL), carbapenemase-producing Enterobacterales (CPE) and vancomycin-resistant enterococci (VRE). For residents undergoing rectal screening, we also collected: years in institution; Katz-Score; hospital admission/antibiotic use within last 6 months; prior colonization with resistant pathogens. Risk factors for colonization with resistant pathogens were assessed using logistic regression. Whole-genome sequencing (WGS) was performed on resistant isolates.

Results: We screened 1185 residents from 16 LTFCs (8 per geographic region) for HAI and antibiotic treatment. HAI-prevalence was 4.1%, with (muco)-cutaneous mycoses (28%) and urinary tract infections (25%) being most common; 2.9% received antibiotics on the day of the survey, 35% received a PPI. Screening for resistant pathogens was done in 605/1185 (51%) residents. ESBL-prevalence was 9.1% [31/340] in Eastern and 13.6% [36/265] in Western Switzerland (P=0.08) [87% Escherichia coli]. No CPE or VRE were detected. Independent risk factors for ESBL-carriage were previous colonization with resistant pathogens [OR 6.1, 95% CI 2.7-13.6], male gender [OR 2.6, 95% CI 1.6-4.5], and PPI use [OR 2.2, 95% CI 1.3-3.8] (Figure). Preliminary WGS analysis showed a high diversity of E. coli sequence types (ST) in Eastern (10 different STs, 42% ST131), but less so in Western Switzerland (3 different STs, 89% ST131).

Conclusions: HAI prevalence in Swiss LTFCs is similar compared to other European countries, whereas antibiotic consumption and antibiotic resistant pathogens are less common. More than one third of the LTFC population received a PPI on the day of the survey. Given the independent association with ESBL-carriage of this potentially modifiable risk factor, this finding merits further study.

A wide spread of sexually-transmitted infections among users of pre-exposure prophylaxis attending the dedicated outpatient clinic in Modena, Italy

Gianluca Cuomo1, Alessandro Raimondi*1, Carlotta Rogati1, Marco Tutone1, Barbara Beghetto1, Giulia Nardini1, Enrica Roncaglia1, Vanni Borghi1, Giovanni Guaraldi1, Maurizio Coppini1, Cristina Mussini1

1Azienda Ospedaliero-Universitaria di Modena, Università di Modena e Reggio Emilia, Modena, Italy

**Background:** Pre-exposure prophylaxis (PrEP) with the association of tenofovir (TDF)/emtricitabine (FTC) is effective in the prevention of HIV transmission. This study aims to investigate the epidemiological characteristics of the users, the effectiveness and security of PrEP, the incidence of sexually transmitted infections (STIs), as well as the adequacy of PrEP requirement.

**Materials/methods:** It is a prospective observational study conducted enrolling all the users attending our PrEP outpatient Clinic from July 2018 until September 2019. We collected epidemiological and clinical data at baseline and during follow-up visits at 1, 3 months and then every three months. We performed serological test for HIV, HBV, HCV, HAV, *Treponema pallidum* and PCR research for *Chlamydia trachomatis* and *Neisseria gonorrhoeae* on urine, rectal and pharyngeal swabs and we measured blood creatinine.

**Results:** 35 people used Prep with a follow-up of at least one month (median 6 months). 97% of them were male, all MSM, 83% Italian, median age of 37 years. Among indications, 12 people (34.3%) reported an inconstant condom use, 11 (31.4%) a previous STI, 2 (5.7%) practiced chemsex, 1 (2.9%) received post-exposure prophylaxis, 2 (5.7%) people didn’t report risky behavior. 30 (85.7%) of them chose on-demand regimen and 5 (14.3%) the daily scheme. At baseline, 13 people (37.1%) were diagnosed with at least one STI. During follow-up, 12 (34.3%) contracted at least one STI, with a median time of 4 months from the beginning of the prophylaxis, 4 users (11.4%) were diagnosed repeatedly. Figure 1 shows the proportion of diagnosed STIs. No new HIV infection was observed. Adhesion to the chosen regimen was 85.7%. Condom use in PrEP was mostly discontinuous. 12 users (34.3%) reported side effects, mostly minor gastrointestinal except for 1 acute renal failure which required PrEP suspension.

**Conclusions:** In our experience, PrEP request is limited to MSMs only. PrEP is effective in preventing new HIV infections. More than 30% of the users at the baseline already had a STI and more than 30% of them developed a STI during the prophylaxis. We recommend PrEP distribution under medical supervision to detect and cure eventual side effects as soon as possible.

Abstract 5161

Clinical experience with ceftazidime-avibactam (CAZ-AVI) in the treatment of infections caused by XDR Klebsiella pneumoniae producing OXA-48 carbapenemase

Andrey Bykov1, Margarita Suvorova2, Igor Sychev3, Elena Burmistrova3, Artur Ismagilov3, Denis Protosenko4, Sergey Yakovlev*2

1Pirogov Russian National Research Medical University, Moscow, Russian Federation, 2I.M. Sechenov First Moscow Medical University (Sechenov University), Moscow, Russian Federation, 3S.S. Yudin City Clinical Hospital, Moscow, Russian Federation, 4Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: In the ICUs of our hospital more than 50% of K. pneumoniae strains show resistance to carbapenems as a result of the production of carbapenemases, mainly OXA-48 type. The aim of our study was to investigate the efficacy of the new antibiotic ceftazidime-avibactam (CAZ-AVI) in infections caused by carbapenem-resistant K. pneumoniae producing OXA-48 carbapenemase.

Materials/methods: In open-label prospective study we analyzed the results of the use of CAZ-AVI in patients with various infections. We included patients who met the following criteria: 1) isolation of K. pneumoniae, resistant to carbapenems, 2) XDR strains, characterized by sensitivity to a maximum of two antibiotics, 3) ineffectiveness of previous potentially adequate therapy. The MIC of antibiotics was studied by broth microdilution method, determination of the type of carbapenemases was carried out by PCR.

Results: We enrolled 22 patients with confirmed infection caused by K. pneumoniae producing OXA-48 carbapenemase. The most common infections were VAP (40.9%) and intra-abdominal infection (22.7%), half of the patients had bacteremia. In most patients the infection was severe [sepsis or septic shock was in 21 patients], the average value of SOFA score was 8.9±3.6. All patients had received antibiotics before CAZ-AVI [median 3] and had failed treatment. The most commonly prescribed agents were carbapenems and polymyxin B. The duration of treatment with CAZ-AVI ranged from 4 to 23 days [an average of 9.3 days]. CAZ-AVI was used in monotherapy or in combination with other antibiotics [in 10 patients with polymyxin B and 5 with tigecycline], since along with K. pneumoniae in 16 patients a second significant pathogen was isolated – P. aeruginosa or A. baumannii. All tested isolates were sensitive to CAZ-AVI with MIC\textsubscript{90} level of 0.06 mg/l. During CAZ-AVI treatment eradication of the pathogens was noted in 90.5% of patients, a clinical cure/improvement was achieved in 72.7%. CAZ-AVI was prescribed an average of 12.9 ± 9.6 days from the beginning of infection; interestingly, CAZ-AVI was prescribed on average 5.4 days earlier to the surviving patients than died patients (P<0.012).

Conclusions: CAZ-AVI has demonstrated good clinical and microbiological efficacy in infections caused by OXA-48 producing K. pneumoniae, for which therapy options are extremely limited.

Rural and urban dogs as a source of ESBL-producing Enterobacteriaceae in northwest Spain

Fátima Abreu-Salinas¹,²,³, Dafne Díaz-Jiménez⁴, Azucena Mora Gutiérrez⁵, Ana María Lopez Beceiro⁴, Luis Eusebio Fidalgo Álvarez⁴, Pilar Lumbreras Iglesias¹,²,³, M. Rosario Rodicio²,³, and Javier Fernández*¹,³

¹Hospital Universitario Central de Asturias, Microbiología Clínica, Oviedo, Spain, ²University of Oviedo, Departamento de Biología Funcional, Área de Microbiología, Oviedo, Spain, ³Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, ⁴Facultade de Ciencias - Campus Terra - Universidade de Santiago de Compostela, Facultad de Veterinaria, Lugo, Spain, ⁵University of Santiago de Compostela, Facultad de Veterinaria, Campus Lugo, Lugo, Spain

Background: Antimicrobial resistance represents a threat to animal and human health worldwide. Dogs constitute a reservoir of antimicrobial resistances and a vehicle for their transmission to humans. Carbapenem- and extended-spectrum-β-lactamase (ESBL)-producing Enterobacteriaceae are categorized as critically important in the World Health Organization list. The aim of this study was to evaluate the fecal carriage of these bacteria among rural and urban dogs.

Materials/methods: Fecal samples from 179 healthy dogs from rural and urban environments in northwest Spain were recovered during May-June 2019 and plated on CHROMagar ESBL (bioMérieux), CHROMID CARBA SMART (bioMérieux) and CHROMagar OXA-48 (bioMérieux) for selection of ESBL- and carbapenemase-producing Enterobacteriaceae. Bacterial identification was performed by MALDI-TOF/MS (Bruker Daltonik). Antimicrobial susceptibility testing of suspicious colonies was carried out with the Microscan system (Beckman Coulter) and interpreted according to EUCAST guidelines. Screening of ESBLs, plasmid-mediated AmpC-beta-lactamases (pAmpCs) and plasmid-mediated colistin resistance encoding genes (mcr1 to mcr5), as well as identification of virulence genes and Escherichia coli phylotypes, were performed by PCR. MLST of E. coli and Klebsiella pneumoniae followed the respective PubMLST schemes.

Results: Forty-six enterobacterial isolates from 33 individuals (18.4%) were positive for ESBLs. They were identified as E. coli (39), K. pneumoniae (3), Enterobacter cloacae (2) and Serratia fonticola (2). All isolates were multidrug resistant (MDR), with resistances to narrow and broad spectrum β-lactams (100%), ciprofloxacin (65.2%) and tobramycin (36.9%), being the most frequent. Among the 39 ESBL-producing E. coli, 27 (69.2%) carried a blaCTX-M gene (blaCTX-M-1, blaCTX-M-14, blaCTX-M-15, blaCTX-M-27), while the remaining nine (23.0%) were positive for blaSHV-12. Furthermore, four E. coli, each from a different dog, were positive for the blaCMY-2-type pAmpC gene. Eight ESBL-producers conforming the ExPEC status belonged to O1:H45-Clade I-ST770 (5), O18:H11-A-ST93 (CC168) (1), O23:H16-B1-ST453 (CC86) (1), and O83:H42-F-ST1485 (CC648) (1) which also satisfied UPEC status. All isolates were negative for mcr-1 to mcr-5 and no carbapenemase-producers were recovered in the study.

Conclusions: Our results showed that healthy rural and urban dogs represent a significant reservoir of MDR Enterobacteriaceae resistant to critical antibiotics. Thus, they should be a key point of epidemiological surveillance in the fight against antimicrobial resistance.

Abstract 5166

Prophylactic antibiotics administration in low- and middle-income countries: what are the consequences on antibiotic resistance? A systematic review

Lison Rambliere1*, Didier Guillemot2, Elisabeth Delarocque-Astagneau2, Huynh Bich-Tram1

1Institut Pasteur, Paris, France, 2Université Versailles Saint-Quentin-en-Yvelines, Guyancourt, France

Background: Antibiotic resistance is one of the greatest threats to global health, particularly in low- and middle-income countries (LMICs). Antibiotic consumption is an important driver of antibiotic resistance and its consumption in LMICs reached 24.5 billion daily doses in 2015 for both treatment and prevention. Despite the ubiquity of prophylactic antibiotic treatment, no systematic review has yet been conducted to provide a global overview of prophylactic antibiotic use and its impact on the emergence and spread of antibiotic resistance in LMICs.

Materials/methods: We conducted a systematic review of studies using prophylactic antibiotics in LMICs published after 2000. We considered both mass drug administration or systematic prophylactic use. If investigated, data on antibiotic resistance following prophylactic antibiotics administration were reported.

Results: In total, 2193 articles were identified and 54 were eligible, comprising 34 unique studies conducted primarily in Africa (85%). Three main populations receiving prophylactic antibiotics were identified and stratified into subpopulations: children under 15 years old (healthy under 2 years old, HIV-exposed or malnourished), pregnant women (healthy, HIV-infected or with risk factor at delivery) and communities (outbreak situations or HIV-infected). Fifteen different antibiotics were prescribed, mainly co-trimoxazole (47%), azithromycin (18%) and amoxicillin (12%).

Sixteen studies (47%) evaluated the impact of prophylactic antibiotic use on antibiotic resistance following administration of co-trimoxazole (50%), azithromycin (38%), amoxicillin (12%), ciprofloxacin (6%) and doxycycline (6%).

Following co-trimoxazole administration, increases were observed in: overall expression of resistance genes (sulfonamide and trimethoprim), rates of co-trimoxazole resistance in S. pneumoniae, and rates of resistance to five different antibiotics in E. coli.

For azithromycin, increases were observed in: overall expression of resistance genes (macrolide), rates of macrolide resistance in S. pneumoniae, and rates of azithromycin resistance in S. aureus and S. pneumoniae.

No changes in resistance rates were detected after ciprofloxacin or doxycycline administration.

Conclusions: We identified a substantial proportion of the global population receiving prophylactic antibiotics in LMICs, with links to increased antibiotic resistance identified in the few studies reporting resistance data. However, consequences of all prophylactic use across target populations have never been evaluated. For future antibiotic prophylaxis implementation, studies should investigate consequences on antibiotic resistance.

Omadacycline in a comparative analysis of *in vitro* activity on *Clostridioides difficile* isolates from Stockholm, Sweden

Angela Camporeale*, Chaitanya Tellapragada¹, Carl Erik Nord², Christian Giske¹²

¹Karolinska Institutet, Department of Laboratory medicine, Division of Microbiology, Stockholm, Sweden, ²Karolinska University Hospital, Department of Clinical Microbiology, Stockholm, Sweden

**Background:** *Clostridioides difficile* is a Gram-positive, anaerobe, spore-forming bacillus that is involved in intestinal infections (CDIs) with a high rate of recurrences. CDI is the most common diarrhea-causing infection in Sweden, with one of the highest incidences amongst European countries. Moreover, the global rise of hypervirulent clones belonging to ribotypes (RT) 027 and 078 increased morbidity and mortality. Although *C. difficile* antimicrobial resistance has decreased recently in Sweden, the burden of finding novel and more efficient antimicrobial drugs is still present. One of the latest options available is omadacycline (OMC), a synthetic modified tetracycline approved by FDA. In this study, OMC has been compared to commonly used antimicrobials for CDI, using a Swedish strain collection.

**Materials/methods:** A total number of 221 *C. difficile* isolates were collected from unique patients during the period 2015-2018 from Karolinska University Hospital, Huddinge, Sweden. Blood agar plates containing antimicrobials were used for agar dilution assay, following CLSI guidelines. The isolates were tested for clindamycin (0.25 – 16 mg/L), erythromycin (0.25 – 2 mg/L), fidaxomicin (0.008 – 1 mg/mL), linezolid (0.25 – 4 mg/L), metronidazole (0.03 – 2 mg/L), moxifloxacin (0.5 – 4 mg/L), vancomycin (0.25 – 2 mg/L) and omadacycline (0.008 – 8 mg/L).

**Results:** A selection of isolates among the most common RTs in Sweden and the hypervirulent RT027 resulted in 57 strains, of which 17 (29.8%) belonged to RT014, 10 (17.5%) to RT002, 9 (15.8%) to RT023, 8 (14%) to RT001, and 13 isolates comprising other RTs including 078, 078/126, 005, 020 and 027. Median (IQR) MIC values (in mg/L) for each of the antibiotics tested were 8 (8-16) for clindamycin, 2 (2-2) for erythromycin, 0.12 (0.06-2) for fidaxomicin, 4 (2-4) for linezolid, 0.5 (0.5-2) for metronidazole, 4 (4-4) for moxifloxacin, 2 (2-4) for vancomycin and 0.5 (0.25-1) for omadacycline. MIC\(_{50}\) and MIC\(_{90}\) values for omadacycline were 0.25 and 2 mg/L respectively.

**Conclusions:** Omadacycline exhibited potent antimicrobial activity, *in vitro*, against the contemporary ribotypes of *C. difficile* causing infections in Sweden. Clinical evaluation of omadacycline in comparison with other antimicrobials agents currently used for treatment of CDI is warranted.

Abstract 5169

Building a predictive score for local risk of respiratory syncytial virus hospitalisation: Normative Outcome Hospitalisation Assessment for Newborns (NOHAN)

Casalegno Jean-Sebastien*, Marine Jourdain1, Rolf Kramer2, Sandrine Couray-Targe3, Anne-Florence Myard-Dury4, Dominique Ploin5, Yves Gillet5, Etienne Javouhey5, Bruno Lina1, Mehdi Benchaib6

1Hôpital de la Croix-Rousse, Institut des agents infectieux, CNR des infections respiratoires (dont la grippe), Hospices Civils de Lyon, Lyon, France, 2European Public Health Microbiology Training Programme (EUPHEM), Lyon, France, 3Service des Données de Santé, Hospices Civils de Lyon, Lyon, France, 4Hôpital Femme-Mère-Enfant, Service des Urgences Pédiatriques, Hospices Civils de Lyon, Bron, France, 5Hôpital Femme-Mère-Enfant, Service de Réanimation pédiatrique, Hospices Civils de Lyon, Bron, France, 6Hôpital Femme-Mère-Enfant, CECOS, Hospices Civils de Lyon, Bron, France

Abstract third-party references: On Behalf The VRS Study Group in Lyon

Background: Respiratory syncytial virus (RSV) infection is the predominant cause of lower respiratory tract infection (LRTI) during the first year of life. There is a strong need for a predictive model for RSV-associated hospitalization (RSVh) in the general pediatric in order to guide future preventive actions. We aimed to develop and validate a risk predictive model for RSVh within the first three months of life.

Materials/methods: Elaboration of the predictive model was based on a development cohort comprising 55180 infants and 594 laboratory-confirmed RSVh between 2012 and 2017. For validation purpose, a prospective cohort of 9268 infants born in 2018 was employed. A retrospective cohort analysis was conducted using univariate and multivariate logistic regression on demographic, laboratory, and clinical data.

Results: Prematurity under 37 weeks of amenorrhea, multiparity, socioeconomic factors, and month of birth were identified as independent risk factors for RSVh and included in the final model. The predictive model showed excellent discrimination performance with an area under the receiver operating characteristic curve of 0.847 [95% CI: 0.833–0.861] in the development cohort and 0.860 [95% CI: 0.834–0.887] in the validation cohort.

Conclusions: It is possible to build-up simple and efficient score that predict RSVh at birth using data commonly available in electronic medical records. Preventive pharmacological and non-pharmacological interventions should target the parents of at-risk infant during the pregnancy follow-up or during the birth hospitalization.

Dalbavancin treatment for prosthetic joint infections in real-life: a national cohort study
Morgan Matt*1, Clara Duran1, Patricia Pavese1, Vincent Le Moing1, Boris Bonnin1, Lydie Khatchatourian1, Pascal Chavanel1, Catherine Lechiche2, Johan Courjon2, Romain Lotte3, Pierre Tattevin3, Vincent Cattoir3, Flore Lacassin-Beller3, Illes Gabriela9, Eric Senneville10, Aurélien Dinh1

1Raymond Poincaré University Hospital - (AP-HP), Garches, France, 2Chu Grenoble Alpes, La Tronche, France, 3Chu Montpellier, Montpellier, France, *Centre Hospitalier de Cornouaille Quimper-Concarneau, Quimper, France, 4University Hospital Dijon-Bourgogne, Dijon, France, 5Centre Hospitalier Universitaire De Nîmes, Nîmes, France, 6University Hospital Nice, Nice, France, 7CHU de Rennes, Rennes, France, 8Centre Hospitalier de Mont de Marsan, Mont-de-Marsan, France, 9CHU Lille-Tourcoing, Tourcoing, France

Background: Dalbavancin is a novel long lasting antibacterial agent with bactericidal activity against gram positive cocci. There are emerging data on bone and joint infections, but none exclusive to prosthetic joint infections (PJI). We aimed to describe the efficacy of dalbavancin on a homogenous cohort of PJI.

Materials/methods: A national retrospective study was performed from July 2017 to November 2018. Eligible patients must have presented PJI and received at least one dose of dalbavancin. We collected patients’ characteristics, indication for treatment, and outcome. Cure was defined as the absence of new antibiotic treatment, and/or new surgical intervention, and/or death from any cause.

Results: Overall, 17 patients from 8 hospitals were included in the study. Mean age was 69.1±11.0 yo; sex ratio (M/F) was 1.43. A total of 6 (35.3%) patients were immunocompromised. Associated infections were abscesses (n=2) and endocarditis (n=1).

Dalbavancin was used after a median of 2.0 lines [range 0-4] of antimicrobial treatment. Bacteria were identified in 16 cases. Main bacteria involved were: Staphylococcus aureus (n=10; 62.5%), with methicillin-resistant S. aureus (n=1; 6.3%); Staphylococcus epidermidis (n=7; 43.8%), with methicillin-resistant S. epidermidis (n=4; 25.0%); other coagulase-negative staphylococci (n=3; 18.8%); Enterococcus faecalis (n=1; 6.3%). Median MIC to dalbavancin was 0.064 mg/L for S. aureus and 0.023 mg/L (IQR 0.011 -0.079) for S. epidermidis. Median MIC to vancomycin was 0.750 mg/L (IQR 0.196-1.0) for S. aureus and 1.5 mg/L (IQR 1.0-2.0) for S. epidermidis. No Dalbavancin-resistant strain was isolated.

Dalbavancin was given as single-drug regimen in 8 (47.1%) patients. Main treatment regimens for Dalbavancin were a weekly 2-dose regimen (1500mg each) in 8 (47.1%) cases, and a single-dose regimen (1500mg) in 3 (17.6%) cases. However, the number of injections varied from 1 to 10 doses.

Clinical cure was observed in 8 (47.1%) patients [median follow-up 42.7 weeks], and all-cause mortality was 11.8%, with 2 patients classified as clinical failures. Finally, 5 (29.4%) patients were on suppressive antibiotic treatment [doxycycline n=3, dalbavancin n=2], with 2 who then presented clinical failure.

No adverse events were reported.

Conclusions: In our experience, Dalbavancin seems safe and effective for treating PJI even in salvage therapy.

**Combination testing of avibactam against multidrug-resistant Gram-negative bacteria**

Rui-Yang Chen*1, Manuel Kussmann1, Markus Obermüller1, Matthias Karer1, Richard Kriz1, Werner Ruppitsch2, Heinz Burgmann1, Heimo Lagler1

1Medical University of Vienna, Department of Internal Medicine I, Vienna, Austria, 2University of Natural Resources and Life Sciences, Institute for Medical Microbiology and Hygiene, Vienna, Austria

**Background:** Inappropriate and excessive use of broad-spectrum antibiotics has led to a high prevalence of multidrug-resistant (MDRGN) bacteria especially of Enterobacteriaceae. These pathogens are often responsible for nosocomial infections such as bacteremia, hospital-acquired pneumonia, as well as intraabdominal and urinary tract infections. Avibactam (AVI) is a broad-spectrum β-lactamase inhibitor which prevents the degradation of beta-lactam antimicrobials and is currently available in a fixed combination with ceftazidime for treatment of Gram-negative nosocomial infections.

**Materials/methods:** In this in-vitro study, antimicrobial susceptibility testing was performed using the checkerboard assay and MIC test strips with agar plates containing avibactam. Not frequently used β-lactam antibiotics such as ceftobiprole (BPR), cefoxitin (FOX) and temocillin (TMO) as well as non β-lactam antibiotics such as fosfomycin (FOF) and tigecyclin (TGC) were tested in combination with AVI (4µg/mL) against clinical multidrug-resistant Enterobacteriaceae (20 E. coli and 22 K. pneumoniae) isolates, including 3/4MGRGN, with the respective resistances. The results were interpreted in accordance with the EUCAST breakpoints except for Cefoxitin and Temocillin for which CLSI and BSAC breakpoints were used, respectively. Characterization of the isolates was accomplished by using whole genome sequencing to identify possible resistance genes.

**Results:** MIC reductions below the susceptibility breakpoints were observed in 14/14 (BPR-AVI), 5/7 (FOX-AVI), 8/9 (TMO-AVI), 1/3 (FOF-AVI) for E. coli and in 11/21 (BPR-AVI), 1/13 (FOX-AVI), 3/11 (TMO-AVI), 5/8 (FOF-AVI) and 0/6 (TGC-AVI) for K. pneumoniae.

**Conclusions:** This study demonstrates the restoration of the antimicrobial activity of all tested agents when combined with AVI except for TGC. BPR-AVI, FOX-AVI, TMO-AVI displayed better activity against E. coli, whereas FOF-AVI was more effective against K. pneumoniae. Future clinical studies are warranted to investigate the value of these antibiotics paired with AVI as a carbapenem sparing alternative for treatment of nosocomial MGRGN infections.

Abstract 5177

Compliance to the WHO moment 2 in German hospitals: first evaluation of detailed hand hygiene before aseptic tasks and procedures in national surveillance module HAND KISS

Janine Walter1,2, Karin Bunte1, Christin Schröder1, Sonja Hansen2, Michael Behnke1, Petra Gastmeier1, Tobias Kramer*1,2,3

1 Charité Universitätsmedizin Berlin, National hand hygiene campaign „Aktion Saubere Hände”, Berlin, Germany, 2 Charité Universitätsmedizin Berlin, Institute for hygiene and environmental medicine, Berlin, Germany, 3 Charité Universitätsmedizin Berlin, National Reference Center for the Surveillance of Nosocomial Infections, Berlin, Germany

Background: Hand hygiene (HH) is one of the most effective measures to prevent healthcare associated infections in healthcare settings. Especially compliance to WHO’s moment 2 (HH prior to aseptic procedures and tasks) is of crucial importance. While compliance generally increased in German hospitals since introduction of direct observation, compliance with moment 2 remained stable on a lower level in comparison. Healthcare workers are often not aware of the proper characterization of aseptic tasks in regards to hand hygiene. Therefore the goal of this study was to identify variation in compliances among different aseptic task and enable a more direct-ed feedback.

Materials/methods: Direct observation to the 5 moments is a voluntary tool of the German national hand hygiene campaign. Observations are performed by trained local IPC staff according to protocol by the WHO and documented in the hand hygiene element of the national hospital infection surveillance system [HAND-KISS]. Aseptic procedures were stratified according to different types of frequent tasks.

Results: Between 2016 and 2018 overall 1320947 indications were observed. 213959 Indications prior to moment 2 were observed (16.2%) on 1907 wards in 422 hospital. While overall median compliance was 57% compliance to moment number 2 was 53%. Since its implementation an increasing number of facilities are observing compliance aseptic procedures with the new stratification. Detailed evaluation showed that there is great variance of compliance among different aseptic tasks (table 1).

Conclusions: Direct observation of compliance is helpful for identifying areas for improvement. Detailing of aseptic procedures in direct observation forms increases insight on barriers and potential lack of knowledge for certain tasks. Thus enabling tailored interventions to improve compliance to hand hygiene prior to aseptic procedures.

Abstract 5180

A new Lichtheimia corymbifera mouse model close to human pathophysiology to test antifungal drugs
Kevin Brunet*1,2,3, Jean-Philippe Martellosio1,2, François Arrive1,2, Thomas Brunet1,2, Isabelle Lamarche1,2, Sandrine Marchand1,2,3, Blandine Rammaert1,2,3
1INSERM U1070, Poitiers, France, 2University of Poitiers, Poitiers, France, 3Poitiers University Hospital, Poitiers, France

Background: Most of the published mucormycosis animal models for antifungal studies are not representative of the human pathophysiology. Drugs are administered 30 min to 24h after spore inoculation, leading to treat spores and not hyphae, the invasive form of the fungus. The aim of our study was to develop and characterize a mouse model of Lichtheimia corymbifera pulmonary infection to test antifungal drugs.

Materials/methods: Male BALB/c mice were immunosuppressed with different corticosteroid (cortisone acetate 250 mg/kg to 500 mg/kg at different times) and/or cyclophosphamide (150 mg/kg to 200 mg/kg at different times) regimen, then intratracheally inoculated with 105 to 107 spores/mouse of Lichtheimia corymbifera. Lungs were collected at various times from one day post-inoculation (dpi) to 4 dpi, and presence of hyphae in tissue was assessed by calcofluor white staining. Intraperitoneal liposomal Amphotericin B (L-AmB; 15 mg/kg/d) was administered at 3 dpi for 4 days. Comparison of fungal load and pulmonary inflammatory cells recruitment between L-AmB treated and untreated mice was studied by quantitative PCR (qPCR) on lung parenchyma, and flow cytometry on bronchoalveolar lavage fluid (BALF) at 6 dpi, respectively. Statistical comparisons were performed using Mann-Whitney test.

Results: Mice receiving 500 mg/kg of intraperitoneal cortisone acetate 3 and 1 day before inoculation of 2.5x10⁵ spores/mouse developed an invasive infection at 3dpi (highlighted by presence of hyphae colored by calcofluor), contrary to mice immunosuppressed with cyclophosphamide alone that did not. All animals died before 10 dpi. Using L-AmB, survival was 60% at 21dpi. Lung fungal load was not different for L-AmB treated and untreated mice at 6dpi due to incapacity of qPCR to differentiate DNA from dead and living fungi. L-AmB induced a significant decrease in neutrophil recruitment in BALF of infected mice at 6dpi compared with untreated mice (4.9% vs 20.4%, p=0.02) but no difference in alveolar macrophage recruitment.

Conclusions: Survival of untreated and L-AmB treated mice in our model was in accordance with outcome of human mucormycosis. Immunomodulation effect of L-AmB could be responsible of changes in BALF cell recruitment and need further investigations.

Impact of immunosuppression on *Clostridioides difficile* infection

Eleftheria Kampouri\(^1\), Matthaios Papadimitriou Olivergeris\(^2\), Tatiana Galperine\(^3\), Emilienne Chavan\(^2\), Antony Croxatto\(^3\), Benoit Guery\(^1\)

\(^1\)Lausanne University Hospital, Infectious Diseases Service, Lausanne, Switzerland, \(^2\)Lausanne University Hospital, Service of Pharmacy, Lausanne, Switzerland, \(^3\)Lausanne University Hospital, Institut of Microbiology, Lausanne, Switzerland

**Background:** Immunocompromised patients present a higher incidence of *Clostridioides difficile* infection (CDI) and an increased risk for adverse outcomes. Data from large prospective cohorts are sparse for this population. In a prospective observational study, we compared the characteristics, severity factors, treatment and outcomes in immunocompromised and non-immunocompromised patients.

**Materials/methods:** This prospective observational study included all consecutive cases of CDI in adult patients, between December 2018 and November 2019, in the University Hospital of Lausanne. CDI was defined as presence of diarrhea or ileus with a positive test. The tests used were an Xpert *C. difficile* polymerase chain reaction (PCR) assay (Cepheid Xpert\(^\text{®}\) C. difficile BT) followed by a C.DIFF QUIK CHEK COMPLETE\(^\text{®}\) enzyme immunoassay (EIA) (Labolife). Severity criteria according to ESCMID (2014) and IDSA (2018) guidelines were assessed. Recurrence was defined as a new episode within 8 weeks after the initial episode.

**Results:** From a total of 87 cases included, at least one factor of immunosuppression was identified in 43 cases (49%), and > 1 factors in 4 cases (hematologic malignancy \(n=18, 38\%), solid tumor \(n=20, 43\%), Solid Organ Transplant \(n=3, 6\%), other immunosuppression \(n=6, 13\%\)). There was no statistically significant difference in age, gender or the Charlson Comorbidity Index between groups. Toxin EIA was more frequently positive in the immunocompromised group (65% vs 42%, \(p=0.053\)). While only 30% of episodes in the immunocompromised group were classified as severe according to the IDSA guidelines, 71% were identified using the ESCMID criteria (vs 58% in the immunocompetent group, \(p=0.159\)). Fever and low albumin were significantly more common in the immunocompromised group (37.5% vs 14%, \(p=0.008\) and 30.4% vs 8%, \(p=0.06\), respectively). Fidaxomicin was more frequently used in the immunocompromised group (39% vs 11%, \(p<0.001\)). The rate of recurrence was higher in the immunocompromised group, but this difference was not statistically significant.

**Conclusions:** Fever and low albumin due to CDI were more frequently present in the immunocompromised group and could be of value in detecting severe disease in this population. The recurrence rate was numerically higher in the immunocompromised group, but this was not statistically significant.

Predictors of mortality in patients with bloodstream infections caused by metallo-ß-lactamases Enterobacterales

Marco Falcone*1, Giusy Tiseo1, Simona Barnini1, Cesira Giordano1, Alessandro Leonildi1, Enrico Tagliaferri1, Spartaco Sani1, Dimitrios Bassoulis3, George L. Daikos4, Francesco Menichetti1

1Pisa, Pisa, Italy, 2Livorno, Livorno, Italy, 31st Internal Medicine Department, Laiko General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 4Athens, Athens, Greece

Background: Metallo-ß-lactamases (MBL)-producing Enterobacterales are increasingly reported in Europe and represent a challenge due to limited treatment options. Few studies have been conducted in patients with bloodstream infections (BSIs) due to MBL-producing Enterobacterales. The aim of this study is to identify predictors of 30-day mortality in patients with BSI by MBL-producing strains.

Materials/methods: This observational study included patients admitted to 3 hospitals in Italy (Pisa and Livorno) and Greece (Athens) from 2018 to 2019. Clinical data, treatment regimens and outcome were collected. Species identification and susceptibility testing were performed by MALDI TOF MS [Bruker Daltonics] and SensiTitre [Thermo Fisher Scientific]. MICs were classified according to breakpoints established by EUCAST. The presence of bla genes was determined by PCR and sequencing. A Cox-regression analysis was performed to identify factors associated with 30-day mortality. Hazard ratio (HR) and 95% confidence interval (CI) were calculated.

Results: A total of 96 episodes of BSI by MBL-producing strains were observed. Of these, 17 (17.7%) were caused by VIM and 79 (82.3%) by NDM-producing Enterobacterales. Forty two patients (43.7%) received ceftazidime-avibactam (CAZ-AVI) plus aztreonam (AZT), 25 (26%) colistin-containing regimens and 22 (22.9%) other combinations containing tigecycline/fosfomycin whereas seven patients (7.4%) received no active antibiotic therapy. Thirty-day mortality rate was 36.5%. Compared to survivors, patients who died were older (75 vs 65 years, p=0.001), had higher Charlson Comorbidity index (6 vs 3, p=0.001), history of solid organ transplantation (SOT) (17.1% vs 1.6%, p=0.05), cardiovascular disease (57.1% vs 24.6%, p=0.001), and septic shock (48.6% versus 18%, p=0.002). At Cox regression analysis, cardiovascular disease (5.257 [2.247 - 12.298], p<0.001), SOT (3.312 [95% CI 1.253-8.756], p=0.016) and septic shock (2.646 [1.251-5.594], p=0.011) were independent predictors of 30-day mortality. Conversely, CAZ-AVI plus AZT was associated with improved survival compared to colistin-based regimen (0.194 [95% CI 0.078-0.482], p<0.001). Figure 1 shows the Kaplan Meier curve according to treatment regimens.

Conclusions: Among patients with BSIs due to MBL-producing Enterobacterales, patients with cardiovascular disease and SOT recipients are at higher risk of poor outcome, while antibiotic regimen with CAZ-AVI plus AZT is associated with reduced 30-day mortality compared to colistin-containing regimens.

Acylated homoserine lactone- (AHL) mediated quorum sensing in dental plaque: an opportunity for novel antimicrobial treatment of oral diseases

Andrea Muras1, Paz Otero-Casal2, Ana María Otero*1
1Dpto Microbioloxia e Parasitoloxia, Universidade de Santiago de Compostela, Santiago de Compostela, Spain, 2Centro de salud Santa Comba/Negreira, EOXI Santiago de Compostela, SERGAS, Santiago de Compostela, Spain

Background: Quorum sensing (QS) processes play a key role in the formation and maturation of bacterial biofilms. In the case of dental plaque, this role has been confirmed for the QS signals AI-2 and the autoinducer peptides (AIPs) in pure cultures of oral pathogens, but so far, the production of acyl-homoserine lactones (AHLs) by relevant oral bacteria could not be confirmed. Therefore, the current paradigm excludes a role of AHLs in dental plaque formation and in the development of oral diseases. In the view of the existence of indirect evidences in the literature indicating a role of AHLs in dental plaque, we have studied the presence and role of AHLs in in vivo and in vitro oral biofilm models.

Materials/methods: We have combined biosensor-based detection techniques with HPLC-MS analysis for the detection of AHLs in different oral samples and in vitro biofilm models and quorum quenching (QQ) activity in oral isolates. We have also studied the effect of the QQ enzyme Aii20J on in vitro oral biofilm formation.

Results: The results that support an important role of AHLs in dental plaque formation are:

- Presence of AHLs in saliva samples of healthy donors and patients suffering different oral pathologies (tooth decay and/or gum disease) and in dental plaque obtained from extracted tooth.
- Presence of a high abundance of oral strains with the ability to quench C6-HSL isolated from a periodontal patient (37.42%) and from a healthy donor (23.20%).
- Effect of the addition of the QQ enzyme Aii20J on different oral biofilms models, reaching up to an 80% of biofilm reduction measured with the xCELLigence® Real Time Cell Analyser (Acea Biosciences, Inc).

Conclusions: These data clearly support a role of AHLs in the formation on dental plaque indicating that the QS network in the oral cavity may be much more complex than the accepted paradigm and opening a new opportunity to find alternative therapies in order to prevent and control oral infections. Further studies are required in order to evaluate the role of AHLs in Gram-negative oral pathogen prevalence and in the equilibrium of the oral microbiome.

Abstract 5185

Markers of inflammation, neural injury and regeneration in a neonatal mouse model of Listeria monocytogenes meningoencephalitis

Jana Seele1,2, Melissa Ballüer1, Simone Tauber1, Stephanie Bunkowski1, Katja Schulz1, Christine Stadelmann1, Andreas Beineke4, Dennis Pägelow5, Marcus Fulde5, Roland Nau*1,2

1University Medical Center Göttingen, Department of Neuropathology, Göttingen, Germany, 2Evangelisches Krankenhaus Göttingen-Weende, Göttingen, Germany, Department of Geriatrics, Göttingen, Germany, 3RWTH University Hospital, Department of Neurology, Aachen, Germany, 4University of Veterinary Medicine Hannover, Department of Pathology, Hannover, Germany, 5Freie Universität Berlin, Institute of Microbiology and Epizootics, Berlin, Germany

Background: Bacterial infections of the central nervous system remain a substantial cause of mortality and long-term sequelae in neonates. To gain more knowledge about the pathogenesis of late-onset listeriosis, a recently developed intranasal neonatal mouse infection model was used (Pägelow D et al, Nat Commun 2018; 9: 4269). The present study analyses neuropathological alterations in brains of neonatal mice suffering from meningoencephalitis caused by Listeria (L.) monocytogenes with a focus on neural repair.

Materials/methods: The brains of 14 neonatal mice with L. monocytogenes meningoencephalitis without antibiotic treatment and 14 controls were analysed by histology, immunohistochemistry and in-situ tailing for neural proliferation and differentiation into neurons, densities of apoptotic neurons, microglia and astrocytes and morphological signs of microglial activation in the dentate gyrus of the hippocampal formation. Moreover, infiltrating blood cells, axonal injury and ischemic lesions were assessed in the brain tissue.

Results: Compared to uninfected controls, mice with L. monocytogenes meningoencephalitis showed a decreased density of dividing cells in the dentate gyrus and less neurogenesis analyzed by staining with anti-PCNA ($p < 0.0001$), anti-Calretinin ($p < 0.0001$) and anti-Calbindin ($p = 0.01$) antibodies, respectively, and an increased density of apoptotic neurons visualized by in-situ tailing ($p < 0.0001$). In infected mice, the density of microglia was higher ($p < 0.0001$), while no difference in the density of astrocytes was detected. Meningeal and/or intracerebral infiltrates were found in sections from 13 of 14 brains of infected animals. The infiltrating monocytes and neutrophilic granulocytes probably contributed to tissue damage. No ischemic injuries and no axonal damage were observed.

Conclusions: In the brains of L. monocytogenes-infected mice a strong immune response was observed which led to tissue injury and an impaired neural regeneration.

Abstract 5188

Plasmid-mediated colistin resistance among human clinical Enterobacterales isolates: surveillance in the Czech Republic, 2018-2019

Marketa Zelendova1,2, Vladislav Jakubu3, Ivana Jamborova2, Katarina Pomorska2, Matej Medvecky4, Helena Zemlickova2, Monika Dolejska1,2,4

1 University of Veterinary and Pharmaceutical Sciences Brno, Department of Biology and Wildlife Diseases, Faculty of Veterinary Hygiene and Ecology, Brno, Czech Republic; 2 University of Veterinary and Pharmaceutical Sciences Brno, CEITEC VFU, Brno, Czech Republic; 3 The National Institute of Public Health, NRL for ATB, Centre for Epidemiology and Microbiology, Prague, Czech Republic; 4 Charles University, Faculty of Medicine, Biomedical Center, Pilsen, Czech Republic

Background: The prevalence of colistin resistance has increased rapidly among Enterobacterales. National surveillance of plasmid-mediated colistin resistance started in the Czech Republic in 2018. The aim of this study was to determine the prevalence and characteristics of isolates with mcr genes from human clinical samples.

Materials/methods: During 2018 and 2019, a total of 704 colistin-resistant isolates (MIC>2mg/l) from human clinical materials were examined for the presence of mcr-1 to mcr-8 genes. Isolates carrying mcr genes were tested for susceptibility to 18 antimicrobials substances by broth microdilution and subjected to whole genome sequencing (WGS) using MiSeq platform. Raw reads assembly was performed by SPAdes v3.12.0 to generate contigs that were used to identify antibiotic resistance genes, bacterial sequence types, and plasmid replicons using ResFinder, MLSTFinder and PlasmidFinder. Transferability of mcr-carrying plasmids was determined by conjugation experiments.

Results: So far, twenty-four mcr-1 (3.7%) and one mcr-4 (0.14%) positive isolates were obtained; other mcr genes were not detected. Isolates carrying mcr-1.1 or mcr-1.2 were identified as Escherichia coli (n=22), Klebsiella pneumoniae (n=2) and Enterobacter cloacae complex (n=1). A total of 18.9% colistin-resistant E. coli isolates subjected to PCR screening carried mcr genes. Most mcr-positive isolates showed resistance to aminopenicillins (n=24), quinolones (n=18) and trimethoprim-sulphamethoxazole (n=15). E. coli isolates belonged to various sequence types and showed diverse antibiotic resistance and plasmid content. The mcr-1 gene was predominantly located on 33 kb IncX4 (n=17) with high level of nucleotide similarity (>99.9%) to each other as well as to plasmids available at GenBank database. The gene was also carried by 60 kb IncI2 (n=4) or large (>150 kb) multidrug-resistant IncHI2 (n=3) plasmids. mcr-4.3 was identified in E. cloacae complex on 8 kb CoIE plasmid. Resistance to colistin was transferred to recipient E. coli laboratory strains via conjugation in the majority of the isolates.

Conclusions: Although this study demonstrated a low prevalence of mcr-positive isolates in patients in the Czech Republic (3.5% in 2018 and 4% in 2019), the occurrence of colistin-resistant bacteria should be considered as a possible risk for public health.

Abstract 5191

Detection of antimicrobial resistance in Mycobacterium abscessus complex by MALDI-TOF MS

Alexandre Godmer*, Nicolas Veziris1, Catherine Eckert1, Salah Gallah2, Alexandra Aubry3, Laurent Benzerara2

1APHP, HUEP, Bacteriology / CMI, equipe 2, INSERM U1135, Sorbonne Université, Paris, France; 2APHP, HUEP, Bacteriology, Paris, France; 3APHP, Pitié Salpêtrière, Bacteriology / CMI, equipe 2, INSERM U1135, Sorbonne Université, Paris, France

Background: Species of the Mycobacterium abscessus complex (MABSC) are opportunistic pathogenic bacteria which are difficult to cure because of natural inducible resistance to clarithromycin (CLA) in certain subspecies. Phenotypic assessment of susceptibility to CLA, which is a major prognostic factor, currently requires 14 days of incubation. The objective of this work was to evaluate the performance of mass spectrometry (MALDI-TOF MS) for MABSC CLA susceptibility determination.

Materials/methods: Eleven MABSC strains genotypically and phenotypically characterized were cultured in liquid medium in absence and presence of CLA. According to our hypothesis, a strain susceptible to CLA would have a significant reduction in the Area Under the Curve (AUC) of the mass spectrum in the presence of CLA compared to control without CLA. Each strain was cultured at initial inoculum of 10^4 or 10^6 CFU/mL for 2 or 4 day incubation. The post-acquisition signal processing, including the AUC normalization, was performed with a program encoded in the R environment. Relative Growth (RG) ratio equal to the normalized AUC in the presence of CLA on the normalized AUC in the absence of CLA was calculated. The RG giving the best separation of strains according to their resistance phenotype was determined.

Results: For the 7 smooth strains but none of the 4 rough strains of MABSC, there was a proportional relationship between densitometry, colony count, and AUC. Normalization method encoded in the R environment resulted in robust and repeatable AUCs. The separation of the strains according to their phenotype was reproducible after a four-day incubation time and a 2.02 RG cut-off. After 4 days of incubation, for the strains studied that were extracted (19/22 strains [86%]), the CLA resistance phenotype was in agreement with reference technique for 17 of them [77% of tests performed].

Conclusions: This inexpensive technique which reduces the diagnosis of CLA resistance in MABSC from 14 to 4 days, appears promising.

Abstract 5192

**Vanco-Test: a rapid test for detection of vancomycin-resistant enterococci**

Anna Bertoncelli¹, Ilenia Rizzotti², Annarita Mazzariol*¹

¹University of Verona, Department of Diagnostics and Public Health, Verona, Italy

**Background:** Enterococci represent an important cause of nosocomial infection. Vancomycin resistant Enterococci (VRE) are microorganism subjected to screening to avoid transmission. The aim of the study was to set up a rapid and inexpensive diagnostic phenotypic test able to detect and/or vancomycin resistant Enterococci in 4 hours or less.

**Materials/methods:** The study was conducted on 59 strains, namely 44 *E. faecium*, and 15 *E. faecalis*. 23 out of 44 *E. faecium* and 2 out 15 of *E. faecalis* were vancomycin resistant, the other were vancomycin susceptible. The pattern of susceptibility or resistance was confirmed by both antimicrobial susceptibility test (broth micro dilution and Etest) interpreted following the EUCAST criteria, and Multiplex PCR for *vanA*, *vanB* and *vanC1/2* as determinant of resistance (1). The principle underlying the test is a change in the phenol red indicator following the fermentation of glucose by microorganisms which causes a lowering of the pH and a consequent color change from red to yellow. The Vanco-Test protocol was defined considering different variables: vancomycin concentration, phenol red solution concentration, amount of bacteria, medium, colonies freshness.

**Results:** Antimicrobial susceptibilities and molecular detection of resistance determinant confirmed the pattern of the strains under study. Vancomycin resistant strains showed the presence of *vanA* determinant, that is representative of our epidemiology. Two resistant strains and two susceptible strains of both species were used to set up the test conditions. Once the conditions were defined the Vanco-Test was performed for all strains under study. The results showed a 100% concordance with antimicrobial susceptibilities and molecular detection of resistance. All results were obtained in a maximum time of 4 hours. Sensitivity and specificity of Vanco-test were of 100%.

**Conclusions:** Vanco-test allows the rapid detection, 4 hours, of VRE microorganisms. It is a very cheap test that not need supply and can be done also home-made. Test must be validated with a largest number of strains, including also other determinants of resistance and with strains isolated directly from clinical samples.

**Presenter email address:** annarita.mazzariol@univr.it
Neurodevelopment outcomes at 24 months of age in ZIKV-exposed and ZIKV-unexposed infants in French territories in the Americas: preliminary results from the ZIKA-DFA-BB cohort study

Rebecca Grant*1, Olivier Flechelles2, Benoît Tressières3, Mama Dialo4, Narcisse Elenga5, Nicolas Mediamolle2, Adeline Mallard4, Jean-Christophe Hebert4, Noémie Lachaume5, Elvire Couchy2, Bruno Hoen3, Arnaud Fontanet1

1Institut Pasteur, Paris, France, 2CHU Martinique, Fort-de-France, France, 3Centre d’Investigation Clinique Antilles - Guyane, Pointe-à-Pitre, France, 4CHU Guadeloupe, Pointe-à-Pitre, France, 5CH Cayenne, Cayenne, French Guiana, 6CH de la Basse-Terre, Basse-Terre, France, 7Centre d’Investigation Clinique Antilles - Guyane, Pointe-à-Pitre, France, 8CHU Nancy, Nancy, France

Background: In utero exposure to Zika virus (ZIKV) is known to be associated with birth defects and neurological complications, collectively known in its most severe presentation as congenital Zika syndrome (CZS). Yet, neurodevelopment outcomes beyond birth remain unclear. The objective of this study was to determine the impact of in utero ZIKV exposure on neurodevelopment at 24 months of age among children born to women who were pregnant during the 2016 ZIKV outbreak in French territories in the Americas.

Materials/methods: ZIKA-DFA-BB is a prospective cohort study of infants born to mothers who were pregnant during the 2016 ZIKV outbreak in Guadeloupe, Martinique and French Guiana. From June 2018 to August 2019, 309 infants who had been enrolled in ZIKA-DFA-BB and had no neurological abnormalities detected at birth completed standardized neurodevelopment assessments at 24 months of age: 213 infants born to women with PCR or serological evidence of ZIKV infection during pregnancy; 96 infants born to women with no evidence of ZIKV infection at the time of delivery. Neurodevelopment assessments included the Ages and Stages Questionnaire (ASQ) for five domains of general development – communication, gross motor, fine motor, problem solving, and personal-social skills; the French MacArthur Inventory Scales (IFDC) for French language acquisition; and the Modified Checklist for Autism on Toddlers (M-CHAT) for behavior. Abnormal ASQ and IFDC outcomes were described as being below validated -2SD and 10th percentile threshold, respectively.

Results: 69 (32.4%) ZIKV-exposed infants and 38 (39.6%) ZIKV-unexposed infants had an ASQ result for at least one of the five domains below the -2SD cutoff (p=0.27). The domains most frequently scoring below threshold in the ZIKV-exposed infants were problem solving and personal-social skills. For the IFDC, there were no differences between ZIKV-exposed and ZIKV-unexposed infants in mean language acquisition (p=0.29) nor in the proportion below the 10th percentile threshold (p=0.19). No difference in M-CHAT behavior disorder screening risk between ZIKV-exposed and ZIKV-unexposed infants was observed (p=0.43).

Conclusions: In the largest cohort of in utero ZIKV-exposed infants without abnormalities at birth to date, there were no apparent differences in neurodevelopment outcomes compared to ZIKV-unexposed infants at 24 months of age.

Presenter email address: rebecca.grant@pasteur.fr
First vancomycin-variable enterococci from France: molecular mechanisms of phenotypic susceptibility

Zahida Mamou 1*, Asma Zouari 1, Sophie Potrel 1, Anaïs Collet 1, Gabriel Auger 1, Vincent Cattoir 1

1 CHU de Rennes, Rennes, France

Background: Over the last decade, a few studies have reported the emergence of vancomycin-variable enterococci (VVE), vanA-positive Enterococcus faecium strains phenotypically susceptible to vancomycin. In France, no VVE have been reported so far. The aim of the study was to characterize the first VVE strains isolated in France and to decipher the genetic basis of mechanisms of phenotypic susceptibility.

Materials/methods: Three strains of E. faecium received at the National Reference Center for Enterococci were included: 2 VVE isolates (17-364.1 and 18-086) and 1 vancomycin-resistant enterococci (VRE) isolate (17-364.2). Note that 17-364.1 and 17-364.2 corresponded to isogenic strains recovered from the same patient. MICs of vancomycin and teicoplanin were determined using the broth microdilution method according to EUCAST guidelines. Detection of van genes was performed by PCR. Genomes were entirely sequenced by Illumina technology (MiSeq), and bioinformatic analysis was done using the CLC Genomics Workbench software (Qiagen). Phylogenetic analysis was carried out using the E. faecium core genome as reference.

Results: Both 17-364.1 and 17-364.2 isolates were positive for vanA. However, 17-364.1 was susceptible to vancomycin and teicoplanin (MICs = 1 mg/L) whereas 17-364.2 was resistant to both antibiotics (MICs >64 mg/L). Phylogenetically, the strains were indistinguishable (0 SNP) and belonged to a new ST close to ST263. The strain 18-086 was positive for vanA and exhibited a susceptible phenotype to vancomycin [MIC = 2 mg/L] and teicoplanin [MIC = 1 mg/L]. It belonged to the ST80 and was not clonally related to the two other strains (3,599 SNPs). The Tn1546 was complete in 17-364.2, which was consistent with the resistant phenotype. By contrast, the transposon was interrupted in both VVE isolates. In 17-364.1, an IS1216 was inserted in vanS deleting the 330-bp 5’ end of the gene. In 18-086, an IS1251 was present in the intergenic sequence upstream of vanH while vanS was not detected. Note that vanR was not detected in both VVE strains.

Conclusions: This is the first description of VVE clinical isolates in France. The molecular mechanism of phenotypic susceptibility relies on the inactivation/deletion of vanRS. The risk of reversion to a resistant phenotype is under investigation.

Abstract 5196

Vaccination uptake in sickle cell disease: results from a London teaching hospital

Katie Isitt*1, Anna Calvert2, Mawiyah Haq1, Paul Heath1, Catherine Cosgrove1

1St George’s, University of London, London, United Kingdom

Background: Sickle Cell Disease (SCD) is common in the UK with an incidence of 1 in 2000 live births. Around 12,500-15,000 people in the UK are living with SCD. People with SCD are at increased risk of infections with encapsulated organisms due to functional asplenia. Public Health England (PHE) and the UK Sickle Cell Society publish recommendations for additional vaccinations required by people with SCD above and beyond those given as part of the National Immunisation Programme (NIP).

Materials/methods: Details of all patients under regular follow up with the Haematology department at a South London teaching hospital were extracted from an electronic database and the patients’ General Practitioners (GPs) were contacted for their vaccination history. 355 patients’ GPs were contacted in writing. Data recorded were Influenza vaccine uptake for the last three years, Pneumococcal Conjugate Vaccine (PCV) uptake, Pneumococcal Polysaccharide Vaccine (PPV) uptake, Meningococcal C (MenC), Haemophilus influenzae B (HiB), Meningococcal ACWY Conjugate (MenACWY-Conj), Meningococcal B (MenB) and Hepatitis B vaccine uptake. For children, the uptake of their routine vaccinations according to the UK NIP was also recorded.

Results: 268/355 records were received (75.5% response rate). The age range of the patients was 0-84 years (median 22 years). Overall uptake of NIP vaccines for those under 18 years was 90%. In children under 18 years, vaccination uptake for additional vaccinations was much lower ranging from 59% for PPV to 13% for MenACWY. Vaccination uptake in adults ranged from 53% for PPV and most recent Influenza vaccines, to 0.7% for the MenB vaccine.

Conclusions: Overall uptake of additional vaccinations in people with SCD is poor. The best uptake was seen for Influenza vaccines and the PPV vaccine. Additional vaccinations in the UK are given by the patient’s GP due to the organisation of funding within the NHS. As a result, the patient must visit their GP separately to receive additional vaccines and the GP must be aware of the additional requirements. We propose that this is a significant contributor to the poor vaccination uptake and intend to explore whether opportunistic vaccination in hospital is an acceptable and effective alternative.

Automated detection of antimicrobial-resistant bacteria based on real-time microbiological data

Vered Schechner*1, Tanya Grossman1

1Tel Aviv Medical Center, Tel Aviv, Israel

Background: The spread of antimicrobial resistance (AMR) is a global public health threat, exposing patients to difficult-to-treat infections. An effective program to prevent the spread of AMR in hospitals includes: early detection of carriers, contact precautions for infected and colonized patients, strict hand hygiene (HH) compliance, environmental cleaning and disinfection, appropriate use of antimicrobials, and early intervention to halt outbreaks. Here we describe implementation of an automated process for AMR detection and assistance with infection control (IC) measures.

Materials/methods: The system was implemented in July 2019 in one tertiary-care hospital in Israel. We defined 6 target organisms: methicillin-resistant Staphylococcus aureus (MRSA), carbapenem-resistant Acinetobacter baumannii (CR-AB), carbapenemase-producing (CP) Enterobacteriaceae, non-CP carbapenem-resistant Enterobacteriaceae, vancomycin-resistant Enterococci, and Clostridium difficile [clinical infection only]. For each target organism, we created a generic algorithm that automatically detects positive results from the microbiology laboratory. We also created an easy-to-use system to manage the IC process upon discovery of a new carrier. The workflow starts with detection of a positive result (performed by the algorithm), automatic creation of an investigation protocol to assist the IC staff, and automatic notification of the patient’s ward regarding the required actions (e.g., isolation, screening of contacts). Finally, we developed an online dashboard that displays each wards’ data regarding the prevalence of resistant bacteria carriers, HH compliance and environmental cleaning audits, and incidence of hospital acquired cases.

Results: Compared to manual review of lab reports, the algorithm correctly detected 99% of the positive samples. As of October 2019, time to patient isolation (from lab result) has decreased significantly from 30h to 2h (for MRSA) and from 34h to 4h (for CR-AB). Standardized investigation of all new cases now occurs within 24h of the positive lab result (72h on weekends). HH compliance increased from 74% to 84%. Overall rates of hospital acquired infections by the 6 target organisms showed slight improvement (from 7.6 to 7.1 cases per 10,000 hospital days, July-Oct 2018 vs July-Oct 2019, respectively).

Conclusions: Full automation of management of resistant bacteria carriers allows focused and timely interventions. It also allows standardized and efficient work processes within the IC unit.

Factors associated with non-vaccination against human papilloma virus among girls aged 14-15 years in France: a pooled cross-sectional analysis

Fadia Dib1,2*, Philippe Mayaud3, Laetitia Longfier4, Pierre Chauvin2, Odile Launay1

1CIC Cochin Pasteur, Paris, France, 2Institute Pierre Louis Epidemiology And Public Health, Paris, France, 3London School of Hygiene & Tropical Medicine, London, United Kingdom, 4IDM Families, Issy-les-Moulineaux, France

Abstract third-party references: The Vaccinoscopie® study group

Background: HPV vaccine is recommended in France in girls since 2007, but vaccine coverage remains very low. The aim of this study was to identify factors associated with non-vaccination against HPV in 14-15 year-old girls in France.

Materials/methods: We used the 2015, 2016, 2017 and 2018 Vaccinoscopie® data sets, a web-based survey conducted by IDM families and funded by GSK on a national sample of mothers selected through quota-sampling to monitor the annual evolution of vaccine coverage, perception and attitudes towards vaccination since 2008. Over the 4 years, a total of 2038 mothers of girls aged 14-15 years answered a self-administered online questionnaire reporting on their daughters’ HPV vaccination. The sample was weighted to ensure representativeness of the target population. Associations between non-vaccination against HPV and potential risk factors were analyzed using univariable and multivariable models. All variables with a p-value <0.25 in the univariate analysis were included in the multivariate logistic regression.

Results: HPV vaccine initiation rates (receiving at least one HPV vaccine dose) among 14-15 year-old girls were 23.4% (95%CI: 19.4-27.4), 23.4% (95%CI: 19.6-27.3), 31.1% (95%CI: 26.9-35.2) and 33.2% (95%CI: 29.1-37.2) in 2015/2016/2017/2018, respectively. Multivariate analyses showed that the use of internet as a source of vaccine-related information when mothers hesitate to vaccinate their child was significantly associated with non-vaccination against HPV compared with mothers who did not use the Internet (adjusted Odds Ratio (aOR)=1.47, 95%CI: 1.04-2.07). Protective factors against non-vaccination included: physician advice (aOR=0.11, 95%CI: 0.05-0.26), perception of HPV vaccination as ‘essential’ (aOR=0.04, 95%CI: 0.02-0.08), and a higher level of education (aOR=0.49, 95%CI: 0.32-0.75). Geographic disparities of HPV vaccine uptake across the five geographic regions of France were observed (p=0.0002), with the highest coverage in the West region (35.2% [95%CI: 29.8-40.6]), and the lowest in the Mediterranean region (17.0% [95%CI: 11.9-22.3]).

Conclusions: These findings will help to inform the design of future interventions to increase HPV vaccine uptake and address geographic disparities in France. Specific education campaigns are required to help vaccine-hesitant parents use the Internet safely when they seek information on vaccination.

Abstract: Time-to-result quantification for different blood culturing workflows in an external microbiology laboratory setting
Judith Fonville*, Marcel Van Den Broek1, Arjan Jansz1, Theo Liebregts1

1PAMM, Veldhoven, Netherlands

Background: Microbiology laboratories are focused on a quick turn-around of diagnostics on patient materials, in particular for blood cultures. Therefore, blood culturing machines on location and rapid antimicrobial susceptibility testing are of interest to shorten the time between sampling and availability of culturing results. We determined and visualised the time of the different components in a blood culturing workflow in four different hospital settings, to evaluate and inform on optimal, tailored workflow choice.

Materials/methods: From our laboratory information system, we extracted the time elapsed between the times at which: the sample was drawn; sample was received; sample was placed in the incubator; a positive signal for growth was measured; a gram staining was performed; a determination was performed; the resistance pattern was determined; and a phone consultation with the clinician about the results. To establish a robust analysis of our daily practice, we evaluate both total overviews as well as medians and the inner 90-percentile of time-differences between the different blood culturing steps. To get an accurate impression of the regular workflow, we only analyse the first blood culturing event for a patient.

Results: A dashboard visualises the time between the different steps in a blood culturing process, for four different hospitals and with the possibility to select all or subsets of micro-organisms.

Figure: Example dashboard histogram displaying the number of hours between sample collection and positive blood culturing signal for E.coli.

The differences between the four hospitals were substantial: the median time between sample collection and positive incubation signal ranged between 11.2 and 23.2 hours. This is largely due to the additional use of a blood culturing system on location in two hospitals

Conclusions: Detailed analysis of the different steps in a blood culturing workflow allows for the investigation of the result of different interventions, such as the use of the blood incubation machines on location for an external laboratory, or the effect of rapid susceptibility testing on the total time to result for the patient. This allows the quantification of the diagnostic steps and deeper insight into different laboratory workflows.

Abstract 5206

Pro-protein convertase subtilisin/kexin type 9 (PCSK9) is elevated in bloodstream infections and correlates with c-reactive protein

Carlo Pallotto*1, Vittoria Scaglione2, Sabrina Bastianelli3, Chiara Busti3, Daniela Francisci1,2

1 University of Perugia, Section of Infectious Diseases, Department of Medicine, Perugia, Italy, 2 University Hospital of Perugia, Infectious Diseases Clinic, Perugia, Italy, 3 University Hospital of Perugia, Laboratory of Virology, Infectious Diseases Clinic, Perugia, Italy

Background: Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a protease involved in low density cholesterol (LDL) metabolism. Moreover, it can reduce lipopolysaccharide (LPS) and lipoteichoic acid (LTA) clearance by LDL-receptor down-regulation. The aim of this study is to compare PCSK9 concentration in patients with laboratory confirmed bloodstream infection (LCBSI) and healthy controls and to evaluate the variations of PCSK9 in patients with LCBSI according to aetiology and outcome.

Materials/methods: We enrolled 92 patients with LCBSI – retrospectively from 2014 to 2018 and then prospectively until September 2019 – and 31 healthy volunteers as controls. LCBSI was defined according to CDC definitions. PCSK9 plasmatic concentration was measured using a commercial ELISA test at admission and, for prospectively enrolled patients, at discharge too.

Results: Mean PCSK9 concentration was 611 ng/ml and 212 ng/ml in patients and controls, respectively (p<0.00001). In patients with negative outcome, PCSK9 was comparable to that seen in patients with positive outcome (623 vs 609 ng/ml, respectively). Patients with a S. aureus infection had a significantly higher concentration of PCSK9. Table 1 show the main characteristics of the study population and the 2 subgroups per aetiology (S. aureus vs other aetiology). The 25 prospectively enrolled patients were tested for PCSK9 at admission and before discharge with a significative reduction of PCSK9 concentration (796 vs 613 ng/ml, p=0.001).

As a post hoc analysis, we made a Paerson’s correlation between PCSK9 and CRP concentrations at admission; it showed a correlation with moderate strength (r=0.54) but significative (p<0.00001).

Conclusions: PCSK9 significantly increased in the inflammatory response to LCBSI, especially in S. aureus infections. Larger studies would better clarify the role of PCSK9 in this disease.

**Abstract 5207**

**Nasopharyngeal carriage of methicillin-resistant Staphylococcus aureus in newly HIV-diagnosed, antiretroviral therapy naïve adults, Dar es Salaam, Tanzania**

Joel Manyahi*,1,2, Sabrina Moyo3, Said Aboud4, Nina Langeland3, Björn Blomberg5,6

1Haukeland University Hospital, Bergen, Norway, 2University of Bergen, Bergen, Norway, 3Bergen, Bergen, Norway, 4Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, 5Haukeland University Hospital, Bergen, Norway, 6University of Bergen, Bergen, Norway

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) are difficult to treat and of concern to public health. Nasal colonization with MRSA is a risk factor for active disease and a particular threat to HIV-positive people who are more susceptible to severe bacterial disease. This is the first study to provide data on nasopharyngeal carriage of MRSA in newly HIV diagnosed adults in a community-setting in Tanzania.

**Materials/methods:** Individuals newly diagnosed with HIV were recruited at six sites in Dar es Salaam, Tanzania, from April 2017 to May 2018, as part of the randomized clinical trial CoTrimResist (ClinicalTrials.gov identifier: NCT03087890). Nasopharyngeal swabs were collected and cultured on sheep blood agar for isolation of *Staphylococcus aureus*. Species identity and methicillin-resistance was confirmed by polymerase chain reaction targeting the *nuc* and *mecA* genes, respectively. Antimicrobial susceptibility was performed by disk diffusion and E-test.

**Results:** Overall nasopharyngeal carriage rate of *Staphylococcus aureus* was 15% (79/537). One-third (n=27) of the isolates were MRSA, corresponding to a 5% MRSA carrier rate among all participants. MRSA isolates were significantly more resistant than methicillin-susceptible *S. aureus* (MSSA) towards gentamicin, ciprofloxacin and erythromycin. While overt clindamycin-resistance was rare in both MRSA (0%) and MSSA (2%), inducible clindamycin-resistance was much more common in MRSA (70%) than in MSSA (27%). The majority of *S. aureus* isolates (85%) were susceptible to cotrimoxazole. All MRSA isolates were fully susceptible to vancomycin and linezolid. In multivariate analysis, residence in Kigamboni and age <30 or ≥60 years were significant risk factors for MRSA carriage.

**Conclusions:** Our finding that MRSA constitute as much as one-third of *S. aureus* isolates calls for prudent antibiotic use. The majority of MRSA isolates were susceptible to cotrimoxazole. While WHO’s strategy for long-term cotrimoxazole preventive therapy may eradicate nasal carriage of MRSA in the short term, it remains to see whether this strategy will promote the emergence of increasingly resistant MRSA in the future.

Antibiotic-metal complexes: where microbiology meets bio-physics

Mariana Ferreira¹, Lucinda J. Bessa¹, Floriana Campanile¹, Dafne Bongiorno², Stefania Stefani², Paula Gameiro*¹

¹Universidade do Porto, LAQV/Requimte, Departamento de Química e Bioquímica, Faculdade de Ciências, Porto, Portugal
²University of Catania, Department of Biomedical and Biotechnological Sciences, Catania, Italy

Abstract third-party references: This research was funded by UID/QUI/50006/2019 with funding from FCT/MCTES through national funds

Background: The misuse and overuse of fluoroquinolones (FQs) have triggered the development of bacterial resistance mechanisms. A strategy to circumvent this problem is the complexation of FQs with divalent metal ions and phenanthroline (phen). These stable complexes, known as metalloantibiotics, show different activity. Antimicrobial activity of FQs and metalloantibiotics was determined against several multidrug-resistant (MDR) isolates of *Escherichia coli* and *Pseudomonas aeruginosa* and methicillin-resistant *Staphylococcus aureus* (MRSA). Biophysical results on the membrane fluidity in absence and in presence of FQs and their complexes were also obtained.

Materials/methods: The minimum inhibitory concentration (MIC) of five FQs and their metalloantibiotics was assessed, by the broth microdilution method. 30 MDR clinical isolates were tested: four of *P. aeruginosa*, eight of *E. coli* and 18 of MRSA. The membrane fluidity of some clinical isolates was evaluated in absence and presence of different concentrations of FQs and metalloantibiotics, using fluorescent probes. The fluorescence anisotropy (r) of 1,6-diphenyl-1,3,5-hexatriene (DPH) and the generalized polarization (GP) of Laurdan (6-dodecanoyl-2-dimethylaminonaphthalene) were analyzed in ATCC controls and clinical isolates.

Results: Similar MIC values were obtained for FQs and metalloantibiotics against the Gramnegative MDR isolates. Nevertheless, in 15 out of the 18 MRSA isolates, metalloantibiotics exhibited a greater antimicrobial activity compared to pure FQs. The MIC values of metalloantibiotics were 4 to 28-fold lower than the ones of pure FQs. The r values obtained for the DPH were very similar among ATCC controls and clinical isolates although it is possible to state that Grampositive bacteria are in a more fluid lipid phase (smaller r). GP experiments evidenced much higher values for Grampositive bacteria, both in ATCC controls and clinical isolates. In presence of antibiotics the GP values varies little but preliminary results suggest that they are slightly smaller in presence of metalloantibiotics.

Conclusions: Metalloantibiotics exhibited an improved antimicrobial activity against MRSA isolates, suggesting that these compounds may be a promising alternative to FQs against *S. aureus*. Biophysical results show that GP values can be a valuable tool to discriminate between Grampositive and Gramnegative strains and seem promising in clarifying the interaction of the metalloantibiotics with bacterial membranes, especially in Grampositive isolates.

Abstract 5211

**Epidemiology and comparative genomics of clinical isolates of Salmonella enterica serotype Typhimurium carrying the virulence-resistance plasmid pUO-StVR2**

Noemí Rodríguez1, Ignacio Montero2, Xenia Vázquez1,3, María Margarita Bances4, María De Toro5, Javier Fernández3,6, María Rosaura Rodicio7,8, M. Rosario Rodicio*1,3

1University of Oviedo, Departamento de Biología Funcional, Área de Microbiología, Oviedo, Spain, 2University of Oviedo, Departamento de Biología Funcional. Microbiología, Oviedo, Spain, 3Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, 4Dirección General de Salud Pública, Laboratorio de Salud Pública (LSP) del Principado de Asturias, Oviedo, Spain, 5Centro de Investigación Biomédica, Plataforma de Genómica y Bioinformática, Logroño, Spain, 6Hospital Universitario Central de Asturias (HUCA), Servicio de Microbiología, Oviedo, Spain, 7University of Oviedo, Departamento de Bioquímica y Biología Molecular, Área de Bioquímica y Biología Molecular, Oviedo, Spain, 8University of Oviedo, Departamento de Bioquímica y Biología Molecular, Oviedo, Spain

**Background:** Among more than 2,600 serovars of Salmonella enterica, S. Typhimurium is one of the most prevalent. This is mainly due to the widespread of a limited number of multidrug-resistant clones, including S. Typhimurium pUO-StVR2, which carries a virulence-resistance plasmid derived from pSLT. In the present study, we focused on the epidemiology, genomic variability and phylogenetic relationships of human clinical isolates belonging to this clone.

**Materials/methods:** All clinical S. Typhimurium isolates (532) received at the “Laboratorio de Salud Pública” (LSP) Asturias, Spain, between 2008 and 2018, were tested for antimicrobial susceptibility according to CLSI. The ampicillin-resistant isolates (416) were screened for the presence of blaOXA-1 and alterations in the nfsA gene conferring resistance to nitrofurantoin, both characteristically associated with the S. Typhimurium pUO-StVR2 clone. Isolates fulfilling these criteria were sequenced by Illumina. Typing of the isolates, as well as identification of resistance and virulence genes, plasmids and prophages were accomplished with “on line” bioinformatic tools [SeqSero, MLST, ResFinder, SPIFinder, VFBD, PlasmidFinder, pMLST, PLACNETw and PHASTER]. A phylogenetic tree was constructed with RAxML, based on SNPs in the core genome.

**Results:** Fifty out of the 416 isolates (12%) were assigned to the S. Typhimurium pUO-StVR2 clone and their genomes were sequenced. Most of them showed the ACSSuT/blaOXA-1-cataI-aadA1-sul1-tet(B) resistant profile conferred by pUO-StVR2, but two variants of this plasmid, lacking tet(B) or cataI, were also detected. pUO-StVR2 (IncFII) appeared either alone or together with plasmids of the incompatibility groups IncX1, IncI1 or IncO1, in which additional resistance genes were located [aadA5, strA-strB, dfrA1P and sul2]. According to phylogenetic analysis, the isolates were closely related and probed to be highly homogeneous with regard to SPIs and virulence genes. However, they showed great variability in prophage content, with 22 prophages distributed into 35 profiles. Of them, only Fels-1, Gifsy-1 and N15 were common to all isolates.

**Conclusions:** Together with other major MDR clones of S. Typhimurium, the pUO-StVR2-harbouring clone has substantially contributed to human salmonellosis in our region along the last decade. During this period, isolates carrying this plasmid have remained relatively stable, with prophages being responsible for the greatest diversity.

Genetic diversity and possible recombination of Rs-BatCoV HKU32 related viruses in southern China
Cheuk Pui Wong*,1, Susanna K. P. Lau1,2,3,4, Hayes Luk1, Syed Shakeel Ahmed1, Jian-Piao Cai1, Pyrear S. H. Zhao1, Jade Ll Teng1,2,3, Kwok-Yung Yuen1,2,3,4, Patrick C. Y. Woo1,2,3,4
1The University of Hong Kong, Department of Microbiology, Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong, 2The University of Hong Kong, Carol Yu Centre for Infection, Hong Kong, Hong Kong, 3The University of Hong Kong, State Key Laboratory of Emerging Infectious Diseases, Hong Kong, Hong Kong, 4The University of Hong Kong, Collaborative Innovation Centre for Diagnosis and Treatment of Infectious Diseases, Hong Kong, Hong Kong

Background: Coronavirus (CoV) belongs to viral subfamily Orthocoronavirinae and further subdivided into four genera, Alphacoronavirus to Deltacoronavirus. Bats are known for being the gene source for both Alphacoronavirus and Betacoronavirus. Novel alphacoronavirus Rs-BatCoV HKU32 was discovered in Rhinolophus sinicus, the same bat reservoir for SARS-related CoV (SARSr-CoV). Recombination of Rs-BatCoV HKU32 with SARSr-CoV was observed in one accessory gene. Similar viruses were found in China with significant genetic diversity, suggesting this virus is more diverse than expected. Further analyses of Rs-BatCoV HKU32 related viruses might reveal its evolutionary history and potential for zoonotic transmission.

Materials/methods: Anal swabs from different bat species were collected and subjected to viral RNA extraction and RT-PCR for CoVs detection. Two samples with Rs-BatCoV HKU32 were subjected to complete genome sequencing. Genomes of Rs-BatCoV HKU32 related viruses were obtained from Genbank. Complete genomes and selected functional genes were further subjected to phylogenetic analyses. To look for possible recombination among these viruses, bootscan analysis was performed using aligned whole genomes.

Results: Complete genome analysis showed that Rs-BatCoV HKU32 shared around 71 to 75% nucleotide identity towards Bt-CoV/Rh/YN2012 strains Rs3376, Rs4259, Rs4125 and Ra13591. According to the species demarcation criteria from International Committee on Taxonomy of Viruses (ICTV), the concatenated 7 domains of Rs-BatCoV HKU32 showed 85.5 to 89.5% amino acid identity towards the viral strains from China, representing Rs-BatCoV HKU32 was a novel viral species sharing close genetic relationship with other alphaCoVs.

Phylogenetic analyses of the whole genomes of Rs-BatCoV HKU32 related viruses revealed that viruses collected from Rhinolophus sinicus clustered together while the one collected from Rhinolophus affinis formed an outlier branch. However, different phylogenetic clustering pattern was observed in spike gene. Two strains of Rs-BatCoV HKU32 clustered closely with BtCoV/Rh/YN2012 Rs3376 followed by BtCoV/Rh/YN2012 Ra13591, suggesting possible recombination among these viruses. Bootscan analysis was carried out using Rs-BatCoV HKU32 as query and breakpoints were found at the genomic position around 20500 and 25500.

Conclusions: Rs-BatCoV HKU32 represented a novel species and was evolutionarily close to BtCoV/Rh/YN2012 viruses from China. Recombination events were found among these viruses, suggesting the possibility of novel emerging AlphaCoVs.

**Background:** Linezolid is an important antibiotic for treatment of the nosocomial pathogen methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant Enterococci (VRE), where linezolid resistance has remained low. However, emergence of linezolid-resistant *Staphylococcus epidermidis* (LRSE) raises concern, as this species is gaining clinical relevance and represents the possibility of resistance transfer to MRSA and VRE. In spite of its clinical significance, LRSE clonal lineages and resistance mechanisms contributing to linezolid resistance spread are poorly explored.

**Materials/methods:** Ninety-three LRSE isolates from infection and colonization, collected in 2004-2016, from six different countries [Germany, Greece, Japan, Spain, Poland and USA], were analyzed. Linezolid susceptibility was evaluated by disk diffusion and minimum inhibitory concentration (MIC). Whole genome sequencing was performed with NextSeq Illumina. Raw data were assembled with INNUca v3.1 pipeline and molecular characterization performed using available resources in CGE and/or ABRIcate. Phylogenetic analysis was performed by C5Phylogeny v1.4.

**Results:** More than 75% of the isolates belonged to sequence types (ST) ST2 (49.5%) and ST22 (28.6%), while the remaining ST5, ST23, ST185, ST186 and ST797 ranged between 1.1 and 6.6%. SCCmec III was present in 80% of the isolates, while SCCmec IV was found in 7.5%. ST2-III and ST22-III clones were distributed across five countries, and some clones isolated in different countries differed by less than 12 SNPs.

All *S. epidermidis* presented a multidrug resistance profile, where high resistance rate (>89%) was observed for beta-lactam, quinolones, aminoglycosides, sulfonamides, mupirocin and phenicols. High-level mupirocin resistance was identified in 60% of the population; however *mupA* gene was only present in 25% of the isolates. Half of the isolates presented a minimum inhibitory concentration (MIC) for linezolid above 256 µg/ml; the remaining isolates had MIC varying from 6 to 128 µg/ml. The *cfr* resistance gene was identified in two ST22 isolates, suggesting mutation as the main mechanism responsible for linezolid resistance.

**Conclusions:** Linezolid-resistant *Staphylococcus epidermidis* clones are multidrug resistant and mainly associated with two clones related to clonal complex 2 (ST2-III and ST22-III), which were disseminated geographically. Mutation was identified as the main mechanism generating linezolid resistance worldwide.

Abstract 5222

Clinical characteristics and prognosis of Staphylococcus aureus Bloodstream Infections in a French General Hospital

Sophie Nguyen*1, Pauline Wallard1, Olivier Oddoux1, Magali Anastay1, Dominique Descamps1

1Béthune Hospital, Béthune, France

Background: This study aimed to evaluate prospectively clinical characteristics and prognosis of SA BSIs in a French General Hospital.

Materials/methods: In our centre, patients with BSIs are evaluated by an ID specialist who collects prospectively clinical and microbiological characteristics, and data on empirical antibiotic treatment. These records are inserted in an anonymous database (Epidata software). An extraction was performed on SA BSIs which occurred during the period from May 1, 2017 to August 31, 2019.

Results: During the study period, 191 SA BSI occurred, which represented 16% of all consecutive BSIs episodes (n=1210). Mean age was 68.3 ± 16.6 years, and 73% of patients were immunosuppressed (mainly diabetes mellitus [n=71, 30%], and neoplasia [n=39, 17%]). There were a high proportion of health care-associated episodes (44%). The most frequent portal of entry was catheter-related infections (22%), followed by BSIs of unknown origin (20%) and bone and joint infections (17%).

Overall, the methicillin resistance rate was 16.3%. Rapid PCR based identification of methicillin resistance SA was performed in 112 episodes (59%).

Severe sepsis rate was 32% (n=62), and shock septic rate was 12% (n=23), with a 7-day mortality rate of 15% and a 30-day mortality rate of 22%.

Age, Vancomycin MICs, methicillin resistance rate, and inadequate empirical antibiotic therapy were not associated to 7-day mortality, whilst Teicoplanin MICs were significantly higher in patients who died (0.64 ± 0.48 vs 0.45 ± 0.24 mg/l in survivors, p=0.02), and a teicoplanin MIC ≥ 0.5 mg/l was associated to a higher 7-day mortality rate than a teicoplanin MIC < 0.5 mg/l (20% vs 7% respectively, p=0.01). The 7-day mortality was lower in patients with PCR use for methicillin resistance SA detection (7% in PCR group vs 25% in No-PCR group, p<0.001).

Conclusions: In our centre, SA-related BSIs are frequently associated to immunosuppression and health care-associated infections. The early mortality rate was lower in case of use of PCR for methicillin resistance SA detection, and surprisingly for strains with a teicoplanin MIC < 0.5 mg/l. Further larger prospective clinical studies are warranted to confirm the impact of teicoplanin MIC on SA BSIs survival.

Abstract 5223

**Interest of a systematic surgical mask wearing policy to decrease nosocomial flu burden at hospital**

Virgine Forget1, Sylvie Gros1, Emilie Barneoud-Rousset1, Marie-Gabrielle Demange1, Marie-Laure Ravry1, Aurélie Fourneret-Vivier1, Monique Poggio1, Loick Combrie1, Jérôme Grosjean1, Alicia Pellicier1, Carine Dumollard1, Anne-Sophie Wielandts2, Isabelle Guinot1, Emmanuel Forestier*1, Franck-Olivier Mallaval1

1Centre Hospitalier Metropole Savoie, Chambéry, Centre Hospitalier Metropole Savoie, Chambéry, chambery, France

**Background:** Wearing a surgical mask is individually recommended to caregivers in presence of a patient suffering from flu to limit the risk of droplet transmission. However, no hygiene guideline suggests implementing a systematic policy of surgical mask wearing by all caregivers and visitors at hospital to decrease the occurrence of nosocomial flu. The main objective of our study was to evaluate whether such a policy could be effective.

**Materials/methods:** A prospective observational study was performed in a non-university tertiary care hospital (1 200 beds, including medical, surgical, rehabilitation wards and long term care facilities [LTCF]) during the 2018/2019 flu season. Wearing a surgical mask was asked to all caregivers and visitors during the entire period in voluntary services. Nosocomial flu cases, defined as influenza proven by PCR occurring more than 3 days after the beginning of patient’s hospitalization, were prospectively investigated in all hospital wards. The rates of hospital-acquired flu cases were compared between services which had implemented the mask wearing policy (MWP) and the others [non MWP].

**Results:** There were 37 MWP and 47 non MWP services. In MWP services, 12 patients (0.58%) developed nosocomial influenza among 2056 patients hospitalized more than 3 days, compared to 48 among 3525 hospitalized patients (1.36%) (p=0.0066) in non MWP services. A total of 65 (3.16%) and 131 (3.17%) patients were hospitalized during the same period because of a community-acquired influenza in MWP and non MWP services, respectively. In medical, surgical and rehabilitation wards, 11 cases of nosocomial flu occurred on 1584 patients (0.69%) in MWP services compared to 43 on 3266 patients (1.32%) (p=0.0528) in non MWP services. In LTCF, only 1 case on 472 patients (0.21%) was recorded in MWP services versus 5 on 259 patients (1.93%) (p=0.0231) in non MWP wards.

The flu vaccination rates among caregivers were similar in MWP and non MWP services (33% versus 30%, p=0.27).

**Conclusions:** A systematic surgical mask wearing policy by all caregivers and visitors at hospital during the flu season could decrease the risk of nosocomial influenza in a context of low caregivers’ flu vaccination coverage.

Conserved host transcriptomic responses to acute infection are observed in the presence of multiple fungal pathogens

Julie Steinbrink*1, Aimee Zaas1, Melissa Johnson1, Ephraim Tsalik2,3, Barbara Alexander1, Christopher W. Woods1, Micah Mcclain1

1Duke University Hospital, Durham, United States, 2Durham VA Health Care System, Durham, United States, 3Duke University School of Medicine, Durham, United States

Background: Invasive fungal infections frequently lead to serious critical illness in patients, however current diagnostic assays have significant limitations. Biomarkers based on pathogen-specific host gene expression patterns in peripheral blood offer potential to improve our diagnostic approaches to these devastating diseases.

Materials/methods: We have studied the transcriptional responses of circulating white blood cells utilizing animal models of Aspergillus, Cryptococcus, and Candida infection, in vitro human models of Candida and Cryptococcus, and human cases of invasive candidiasis. Logistic regression models were applied to gene expression data (RNA sequencing or microarray) to identify transcriptomic classifiers capable of identifying each type of infection as well as to assess for common antifungal response pathways.

Results: We have independently developed host gene expression classifiers for each pathogen, and shown that separate biomarker sets are capable of diagnosing infections with each of these 3 organisms. An Aspergillus classifier diagnoses aspergillosis despite variable immunosuppression (auROC 0.94). A Cryptococcus classifier distinguishes fungal from bacterial infection with 94% sensitivity and 89% specificity, while the murine candidemia classifier was able to discriminate between fungal and bacterial infection with 98% sensitivity and 96% specificity. Furthermore, we derived a transcriptomic classifier in human subjects that was capable of simultaneously and accurately differentiating multiple infectious phenotypes (auROC for Candida 0.98, bacteria infection 1.0, viral 1.0, and healthy 0.99).

However, when combining data across these different studies we were able to discover common aspects of the antifungal response shared across these very different infections. Thus, despite non-overlapping gene lists a cryptococcal classifier accurately identifies Candida infection and vice versa. Furthermore, we show that the host responses to Cryptococcus and Aspergillus share 15% of their top genes, including CXCR4 and IL10.

Conclusions: Host gene expression classifiers can accurately discriminate fungal infection from other illness phenotypes and show promise as novel diagnostic tools. These data demonstrate that there are also conserved host responses observed at the level of the transcriptome in the presence of a variety of fungal pathogens. These shared responses offer the potential for broad applicability of such assays in real-world practice.

Variability in ceftazidime exposure and probability of target attainment of different dosing regimens of ceftazidime in critically ill patients with a proven or assumed Pseudomonas aeruginosa infection

Annabel Werumeus Buning1, Caspar Hodiamont1, Natalia Lechner1, Paul Elbers1, Nicole Juffermans1, Ron Mathot1, Reinier Van Hest1

1Amsterdam UMC, Amsterdam, Netherlands

Background: Ceftazidime is a third generation cephalosporin antibiotic with time dependent activity (T>MIC) used as first line treatment option in the treatment of Pseudomonas aeruginosa infections in critically ill patients in the Netherlands. Optimization of dosing may improve the outcome of these high mortality infections. Aim was to investigate the magnitude of the variability in ceftazidime exposure and its causes, as well as the PK/PD target attainment (PTA) of different dosing regimens of ceftazidime in critically ill patients with a Pseudomonas aeruginosa infection. Secondary objective was to explore associations between PTA and microbiological cure.

Materials/methods: In this retrospective observational population pharmacokinetic study, blood samples were collected for ceftazidime concentration measurement and P. aeruginosa isolates were collected for MIC measurement. With the collected data a population PK model was constructed to estimate variability in exposure and PTA for the targets 100%T>MIC and 100%T>4xMIC.

For the secondary objective, patients with at least two subsequent P. aeruginosa isolates were enrolled for microbiological cure analysis.

Results: Ninety six patients yielded 368 ceftazidime concentrations. In a 1-compartment model, the use of continuous veno-venous hemofiltration was negatively associated with ceftazidime clearance. Furthermore, creatinine clearance and comorbidities including hematologic malignancy, trauma or head injury (factor 1.57, 1.19 and 2.07 respectively) were found to have a positive correlation with ceftazidime clearance, explaining 84% of variability in ceftazidime clearance.

MIC values from P. aeruginosa isolates were measured for 32 treatment courses. PTA was 100% for the 100% T>MIC, and 59% for the 100% T>4xMIC target. Patients receiving loading doses before continuous infusion demonstrated higher target attainment rates in the first 24 hours of treatment compared to other patients for 100%T>4xMIC [0% vs 64%; P=0.017].

For 17 patients the endpoint microbiological cure could be assessed. Only one patient (5.9%) achieved microbiological cure. 9 (53%) isolates of patients became resistant (≥2 dilution steps MIC increase) during therapy.

Conclusions: Critically ill patients may be at risk for underexposure to ceftazidime. A loading dose is recommended for target attainment within the first 24 hours of treatment. Furthermore, development of resistance of P. aeruginosa against ceftazidime is common during therapy with ceftazidime.

Abstract 5230

Activity of ANT2681, a Novel metallo-beta-lactamase inhibitor in Combination with meropenem against metallo-beta-lactamase-positive Enterobacterales collected from hospitals world-wide in 2018

Ian Morrissey*1, Thomas Valmont1, Cyntia De Piano1, Nicolas Sprynski2, Carole Sable2, Martin Everett2, Magdalena Zalacain2

1IHMA, Monthey, Switzerland, 2ANTABIO, Labège, France

Background: The spread of MBLs world-wide, especially NDM, is well documented and represents an unmet medical need. ANT2681 is a novel MBL inhibitor with a specific, non-chelating, mechanism of action involving competitive binding to conserved regions on MBLs. ANT2681 is currently in pre-clinical development in combination with meropenem. This study investigated the activity of meropenem/ANT2681 against MBL-positive Enterobacterales clinical isolates collected in 2018.

Materials/methods: MICs were determined by broth microdilution against MBL-positive isolates from Europe (n=231), Latin America (n=80), Asia-pacific (n=111), Africa (n=75), the Middle East (n=30) and North America (n=11). These included 452 NDM, 78 VIM, 5 IMP and 3 NDM+VIM (Citrobacter spp. (14), Enterobacter cloacae (90), other Enterobacter spp. (9), Escherichia coli (60), Klebsiella pneumoniae (294), K. oxytoca (15), K. aerogenes (4), Morganella morganii (5), Proteus mirabilis (9), Providencia rettgeri (5), P. stuartii (19), and Serratia marcescens (14).

Results: A summary of MIC data (mg/L) for meropenem/ANT2681 and comparator antimicrobials is shown below.

MIC₅₀/MIC₉₀ concentration required to inhibit 50%/90% of the bacterial population.

¹ANT2681 [fixed 8 mg/L]. ²taniborbactam [fixed 4 mg/L].

Conclusions: Meropenem/ANT2681 was the most active against NDM sub-populations and the most active jointly with cefiderocol against all MBL combined plus the IMP isolates but it was less active against the VIM strains. Meropenem/ANT2681 was also active against most cefiderocol non-susceptible NDM-positive isolates (71 of 73 strains). Meropenem/ANT2681 is a promising potential therapeutic option for the treatment of MBL-positive Enterobacterales, especially those carrying NDM, and warrants further development.

Use of N-acetylcysteine in critically ill patients with septic shock caused by carbapenem-resistant Klebsiella pneumoniae and Acinetobacter baumannii: a case-control study

Alessandra Oliva*1,2, Alessandro Bianchi3, Alessandro Russo4, Giancarlo Ceccarelli1, Fulvio Aloj2, Danilo Alunni Fegatelli5, Claudio M. Mastroianni1, Mario Venditti1

1Department of Public Health and Infectious Diseases, Sapienza University of Rome, Roma, Italy, 2IRCCS Neumod, Istituto Neurologico Mediterraneo, Pozzilli, Isernia, Italy, 3Infectious Diseases Unit, University of Modena and Reggio Emilia, Modena, Italy, 4Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, 5Department of Statistical Science, Sapienza University of Rome, Rome, Italy

Background: Carbapenem-resistant Klebsiella pneumoniae (CR-Kp) and Acinetobacter baumannii (CR-Ab) represent nowadays an important cause of severe infections in Intensive Care Unit (ICU) patients and mortality rates are significantly associated to septic shock. N-acetylcysteine (NAC) is a mucolytic agent with antioxidant and anti-inflammatory properties, showing also in-vitro activity against several microorganisms including CR-Kp and CR-Ab and a synergistic interaction with colistin or meropenem. Aim of the study was to evaluate the effect on 30-day mortality of the addition of intravenous NAC to antibiotic therapy in ICU patients with septic shock caused by CR-Kp or CR-Ab.

Materials/methods: Retrospective, observational case:control study (1:2) in patients with septic shock caused by CR-Kp or CR-Ab hospitalized in two different ICUs with a dedicated Infectious Diseases consultant [IRCCS Neuromed, (Pozzilli) for cases and Sapienza University (Rome) for controls]. Cases included patients receiving NAC (1500 to 3000 mg/die divided q12h) in combination with antimicrobials, controls included patients not receiving NAC. Cases and controls were matched for age, SAPS II score, causative agent and source of infection. Univariate and multivariate analyses for risk factors associated with 30-day mortality were performed.

Results: No differences in age, sex, SAPS II score, cause of ICU admission (except for stroke) or time to initiate definitive therapy were observed between cases and controls. Colistin was more frequently used as definitive therapy in cases as compared to controls (80% vs 55%, respectively, p=0.02). Pneumonia (66.7%) and central lines related bacteremia (30%) were the leading infections, mostly caused by CR-Kp (60%). Overall, mortality was 48.9% [33.3% in cases vs 56.7% in controls, p=0.051]. At the univariate analysis, risk factors for mortality were age (p=0.015), time to initiate definitive therapy (p=0.017), CR-Ab infection (p=0.001), no definitive therapy with ≥2 antibiotics displaying in-vitro activity (p=0.002). At the multivariate analysis, independent risk factors for mortality were not receiving NAC (p=0.002) and CR-Ab infection (p=0.034) whereas therapy with 2 in-vitro active antibiotics (p=0.014) and time to initial definite therapy were protective (p=0.026) (Table 1).

Conclusions: A combined use of NAC plus antibiotics might reduce the 30-day mortality rate in ICU patients with septic shock caused by CR-Kp and CR-Ab.

Abstract 5233

Therapy directly observed by video for the supervision of tuberculosis treatment: experience in a series of patients from Cali, Colombia, 2019

María Elena Tello-Cajiao1, Jose Fernando Garcia-Goez2, Nelson Romero-Rosas3, Santiago Ardila-Giraldo*3, Juan Camilo Mosquera-Hernández3, Luis Gabriel Parra-Lara3

1Fundación Valle del Lili, Centro de Investigaciones Clínicas, Cali, Colombia, 2Fundación Valle del Lili, Internal Medical Department - Infectology Service, Cali, Colombia, 3Universidad Icesi, Cali, Colombia

Abstract third-party references: Secretaria de Salud Municipal de Cali, Fundación Valle del Lili, Universidad Icesi

Background: Tuberculosis (TB) programs have performed treatment supervision by Direct Observation Treatment (DOT) strategy, because the adherence needs to be guaranteed to avoid unfavorable outcomes. Adequate adherence to TB treatment with DOT strategy has been reported (90%), but in some contexts it can lead to catastrophic expenses in time and money for patients. As an alternative, the Video Directly Observed Therapy (VDOT) arises, which consists in the use of a videophone or other equipment to monitor the medications ingestion remotely. This work described the experience of the implementation of VDOT strategy for TB treatment supervision in a group of patients from Cali, Colombia.

Materials/methods: a description of a prospective case series of patients with new TB diagnosis between February 2019 and December 2019 was performed at Cali, Colombia. Subjects were recruited until May 2019 and were followed every day during the first and second phase of the treatment through video calls made with smartphones. The participants were characterized according to sociodemographic, clinical, laboratory variables, perception of the strategy and costs. The categorical variables were summarized in frequency tables and the quantitative variables according to their distribution. Significant p values <0.05 have taken and 95% Confidence Intervals were used for the analysis of the proportions.

Results: 221 potentially eligible patients were evaluated, of which 23 were recruited. 60% were men, with median age in 37 years old; the youngest patient was 19 years old and oldest patient was 82 years old. All subjects had health insurance, 91% were full-time workers and came from the urban area. 73% had pulmonary TB, 17% pleural TB and one had lymph node TB. During the first phase, a median of 47 doses were monitored by VDOT, achieving an adherence of 99.81%. Patient had to make an average of 3 visits for dispensing medications in the first phase, spending a median of $ 6.00 US on transportation. The second phase follow-ups are continued.

Conclusions: up to now, the strategy has been well tolerated and accepted. VDOT is proposed as a flexible and viable alternative to DOT therapy in selected patients from Cali.

Abstract third-party references: Hellenic Society of Chemotherapy Hellenic Institute for the Study of Sepsis

Background: Invasive infections caused by KPC-Kp are associated with high mortality and new treatment options are urgently needed. A prospective multicenter observational study was conducted to evaluate the therapeutic efficacy of CAZ/AVI against serious KPC-Kp infections.

Materials/methods: The study was conducted under a National Registry in 15 tertiary-care hospitals between January 2018 and April 2019. Inclusion criteria were infections caused by KPC-Kp and treatment with CAZ/AVI >72h. A sub-cohort among these patients with KPC-Kp bacteremia was matched with a historical cohort with bacteremia treated with other antimicrobial agents using propensity score.

Results: A total of 168 patients were enrolled and 146 were included in the analysis. Mean patients age was 60.6 (±17.1) with Charlson co-morbidity index 2.9 ± 2.8, APACHE II 12.8 ± 7.5, SOFA score 7.0 ± 4.4 and Increment Score: 6.9 ± 3.7. Patients were suffering from bacteremia (102), VAP/HAP (27), cUTIs (15) and other infections [2]. Fifty had septic shock and 96 sepsis (by Sepsis-3). By McCabe scoring, 47 patients had ultimately fatal and 22 rapidly fatal underlying disease. For empirical treatment, 58 patients received no active agent and the remaining received at least one active drug. For definitive therapy 65 patients received monotherapy with CAZ/AVI and 81 patients received CAZ-AVI in combination with at least another active agent. At 14-day, clinical success was observed in 87.2% of participants and eradication of the infecting organism occurred in 56.4%. Resistance to CAZ/AVI was observed in 3 isolates during treatment. Mortality rates at 14-day and 28-day was 7.1% and 15.5% respectively. The 28-day mortality among the 71 KPC-Kp bacteremia patients treated with CAZ/AVI was significantly lower than that observed in the 71 patients used as controls [18.3% versus 40.8%, p=0.005]. In multivariate analysis, among the 142 KPC-Kp bacteremia cases, ultimately fatal [odds ratio [OR], 3.4; 95% confidence interval [CI], 1.2-9.5; p=0.02], and rapidly fatal disease [OR, 6.4; 95%CI, 2.0-20.5; p=0.002] were independent predictors of mortality whereas treatment with CAZ-AVI [OR, 0.3; 95%CI, 0.13-0.71; p=0.006] was the only variable associated with survival.

Conclusions: CAZ-AVI appears to be an effective treatment against serious infections caused by KPC-Kp.

Epidemiology and risk factors of CC398 Staphylococcus aureus bone and joint infections

Kevin Bouiller*1,2, Didier Hocquet1,2, Marlène Sauget1, Xavier Bertrand1,2, Catherine Chirouze1,2

1Centre hospitalier régional universitaire de Besançon, Besançon, France, 2Laboratoire Chrono-Environnement, Besançon, France

Background: Staphylococcus aureus (SA) is the leading pathogen implicated in bone and joint infections (BJI). The clonal complex 398 (CC398) has emerged worldwide for several years. CC398 MRSA lineage is associated with livestock and most often responsible of colonization and mild infection in humans and animals. In contrast, CC398 MSSA is a frequent source of infections in humans, and was described frequently in serious infections such as blood stream infections. A particular ability of this clone to cause BJIs remains questionable, since some studies have described CC398 MSSA in prosthetic joint infection (PJI) and diabetic foot infection. Here, we described the long-term epidemiology of CC398 among SA isolated from BJI and identified risk factors associated with CC398.

Materials/methods: We screened all bone and joint samples (per-cutaneous joint fluid aspiration, bone or joint surgical sample) with SA-positive culture in our university hospital (France) between January 2010 and December 2017. CC398 isolates were detected with MALDI-TOF MS and confirmed by a specific PCR. We retrospectively extracted clinical informations from patients medical records. Conditional logistic regression was used for univariate and multivariate analysis.

Results: We identified 124 CC398 isolates among the 958 BJI-associated SA. The proportion of CC398 among SA increased steadily from 3% in 2010 to 28% in 2017. All the 124 BJI-associated CC398 were susceptible to methicillin. The distribution of BJI types due to CC398 and non CC398 isolates was similar. In multivariate analysis, age (p=0.034, OR=3.9), McCabe score (high comorbidity score; p=0.005, OR=5) and inoculation mechanism (p=0.020, OR=3.7) were associated with PJI-related CC398. The year of infection (p<0.001, OR=1.6), Charlson’s score (p=0.001, OR=1.5) and grade 4 (severe) of the International Working Group of the Diabetic Foot classification (p<0.001, OR=8.5) were associated with DFI related CC398.

Conclusions: We showed here the emergence and spread of CC398-MSSA in BJI, suggesting a well-adapted fitness of this clone to humans and bone. Patients with comorbidities are at high risk of CC398 MSSA PJI and DFI. The spread of CC398 in the community and hospital settings remains unclear and further epidemiological studies are needed to identify the determinants of its success.

**Phage susceptibility testing with lensless imaging technique**

Prisca Perlemoine*1, Pierre R. Marcoux1, Emmanuel Picard2, Alexis Maire3, Marc Zelsmann3, Emmanuel Hadji2, Eric Lacot4

1Université Grenoble Alpes, CEA Leti, Grenoble, France, 2Université Grenoble Alpes, CEA IRIG, PHELIQS, SINAPS, Grenoble, France, 3Université Grenoble Alpes, CNRS, LTM, Grenoble, France, 4Université Grenoble Alpes, CNRS, LiPhy, Grenoble, France

**Background:** With the rise of antibiotic resistance, phage therapy is seen as a promising alternative to cure infection to multi-resistant bacteria strains. However, phage susceptibility tests currently carried out are time-consuming and are not compliant with the automated environment of hospital laboratories. In this work, we present a method for phage susceptibility testing through optical density measurement with the use of lensless imaging technique.

**Materials/methods:** Liquid samples containing bacteria and phages are loaded in a custom-made microfluidic card. The card has been machined in a 5-mm thick aluminum sheet and is composed of 8 wells of 3 mm diameter. It is sealed on one side by a MicroAmp adhesive film and on the other side by a PDMS film to insure optical transparency of the wells. Moreover, the use of PDMS, a material permeable to oxygen, enables better growth condition of the bacterial culture. The microfluidic card is put on a 3.3 cm2 CMOS imaging sensor, extracted from a CANON dslr camera. It is illuminated by a screen paired with a 560 nm spectral filter to provide a homogeneous monochromatic lighting over the whole sensor area. The large imaging area of the sensor, enables to simultaneously monitor the level of light transmitted through the entire set of wells of the microfluidic card and hence to compute the optical density of a dozen sample without the need of mechanical elements.

**Results:** With this prototype, we can monitor the decay or increase of the optical density suspension to determine respectively the lysis or growth of the bacteria under test. A first proof of concept has been done using *Pseudomonas putida* ATCC1 2633 bacteria with phage gh-1. We are able to provide a reliable result of optical phage susceptibility testing in less than 4 hours.

**Conclusions:** The prototype shown here is compact, inexpensive (<1k€) and is compliant with automated environment of hospital laboratories. Moreover, it is versatile and can be used for other application such as lysis plaque imaging to provide a fast measurement of a viral titer of a bacteriophage suspension.

Abstract 5240

Sequential time-kill experiments to characterize lipopolysaccharide-modifying genes involved in polymyxin resistance in *Escherichia coli* and *Klebsiella pneumoniae* carrying mcr-1

Hariyanto Ih*1,2, Nicolas Gregoire1,3, William Couet1,3, Sandrine Marchand1,3, Julien Buyck1

1Université de Poitiers, INSERM U1070 - Faculté de Médecine et de Pharmacie, Poitiers, France, 2Universitas Tanjungpura, Pharmacy Department - Faculty of Medicine, Pontianak, Indonesia, 3Centre Hospitalier Universitaire (CHU) de Poitiers, Service de Toxicologie et de Pharmacocinétique, Poitiers, France

**Background:** Resistances of Gram-negative bacteria to the last resort drugs polymyxins are on rise. It was previously reported that a MCR-1 plasmid encoding a phosphoethanolamine transferase lead to low-level resistance. Sequential time-kill study to determine the role of MCR-1 in the development of additional adaptive resistance to colistin and polymyxin B was presented at ECCMID 2019 (P1383). To determine the mechanisms involved in the impact of MCR-1 during exposition to polymyxins, genes leading to lipopolysaccharide modifications were analyzed by RT-qPCR and sequencing.

**Materials/methods:** *In vitro* selection of high-level polymyxin resistance in MCR-1 transconjugants of *E. coli* J53 (EC_MCR-1) and *K. pneumonia* R2292 (KP_MCR-1) were obtained by sequential time kill-curve (TKC) experiments in presence of colistin (CST) and polymyxin B (PMB). Expression of 11 genes (*pmrA, pmrB, phoP, phoQ, pmrC, pmrE, lpxM, arrT, cptA, lpxT* and *eptB*) assumedly involved in polymyxin resistance were analyzed quantitatively by Real-Time PCR method. The efficiency of amplification and the relative expression were analyzed by *t*-tests and 2^-∆∆CT method. In parallel, these genes were sequenced to determine the mutations occuring during polymyxins exposition.

**Results:** For all genes in highly resistant EC_MCR-1 and KP_MCR-1 strains, no mutations were found compared to the wild type strains. In comparison to wild type isogenic strain, the expression of 11 genes was increased in EC_MCR-1 before contact with antibiotic but not in KP_MCR-1. After contact with PMB and CST, all genes were down-expressed in EC_MCR-1. Otherwise, in KP_MCR-1, regulator genes *pmrA/B* and two effector genes, *pmrC* and *pmrE*, were slightly over-expressed. Moreover, in KP_MCR-1, *arrT* was significantly over-expressed up to 29-fold in CST, but only 4.5-fold in PMB (*P*<0.05).

**Conclusions:** The presence of MCR-1 in *E. coli* induced an overexpression of genes involved LPS modification pathway without polymyxins. However, the adaptation in presence of polymyxins was mainly due to the presence of MCR-1. In *K. pneumoniae*, the role of *arrT* in the adaptative resistance of polymyxins is of importance. Our findings suggest that plasmid MCR-1 favor selection of another resistance mechanism by different pathways for each strain leading to develop high-level resistance especially under colistin pressure but less in polymyxin B.

**Abstract 5241**

**Penicillin-binding protein 2a temperature-sensitive folding defect: a new path to tackle methicillin resistance in *Staphylococcus aureus***

Melanie Roch*, Emmanuelle Lelong¹, Roberto Sierra¹, Olesya Panasenko¹, Adriana Renzoni¹, William Kelley¹

¹University of Geneva, Geneva, Switzerland

**Background:** *Staphylococcus aureus* is a major human pathogen and represents a clinical challenge because of widespread antibiotic resistance. Methicillin resistant *S. aureus* (MRSA) originates by the horizontal acquisition of *mecA* encoding PBP2a, an extracellular membrane anchored transpeptidase which confers resistance to β-lactam antibiotics by allosteric gating of its active site channel. Protein folding in the extracellular hostile environment is a critical step to assure proper enzyme configuration and activity.

**Materials/methods:** We studied the biochemical proprieties of purified PBP2a including its unfolding profile by thermal shift assay using Sypro orange and its allosteric mechanism by in vitro competition with bocillin-FL, a fluorescent β-lactam. In parallel, we performed the double knock out of PrsA and Htra1, two extracellular folding factors upregulated in presence of cell wall active antibiotics, in the MRSA strain COL. β-lactam susceptibility testing and PBP2a western blot were used to monitor methicillin resistance. We looked for additional factors involved in PBP2a quality control, by screening double mutants of *htrA1* combined with 25 other proteases using the Nebraska Transposon Mutant Library.

**Results:** Purified PBP2a showed a pronounced unfolding transition initiating at physiological temperatures leading to irreversible precipitation and complete loss of activity. Dual disruption of PrsA and Htra1 synergistically restored sensitivity to β-lactam and was enhanced by minor temperature shift, consistent with folding defect at physiological temperature. Additional experiments demonstrated that the extracellular chaperone PrsA provides anti-aggregation activity and that the Htra1 protease cleans up misfolded PBP2a and its degradation fragments created by other unknown proteases. Screening for additional factors revealed that at least 2 other proteases, respectively CtpA and PrsS, play a role in PBP2a quality control. Inspection of the PBP2a 3D-structure revealed two potential folding weak points composed of non-sequential anti-parallel β-sheets including the key allosteric domain regulating the active site opening.

**Conclusions:** The concordance of biochemical and genetic data highlights the necessity of extracellular protein folding factors for expression of MRSA β-lactam resistance. Targeting the PBP2a folding pathway represents a new particularly attractive adjuvant strategy to combat antibiotic resistance.

**Background:** Tuberculosis (TB) is one of the world’s deadliest diseases. In 2018, >10.0 million people around the world became sick with TB disease and there were 1.3 million TB related deaths. It is clinically important to differentiate *Mycobacterium tuberculosis* (MTB) complex organisms as members can possess differing antimicrobial susceptibility profiles and transmission rates, which in turn will aid in patient management. Unlike MTB, *Mycobacteroides abscessus* has emerged as an important respiratory pathogen in patients with cystic fibrosis. *M. abscessus* complex species cannot be differentiated by single gene sequencing and differentiating these species complexes is time consuming, highly subjective and expensive to perform. MALDI-TOFs ability to discriminate these organisms is limited. Therefore, Ultra high-resolution mass spectrometry employing nano-liquid chromatography coupled with the Orbitrap™ mass analyzer was used to obtain the discriminatory power necessary to identify the relevant species members.

**Materials/methods:** Four reference species from *M. tuberculosis* complex: *M. tuberculosis* (ATCC 27294), *M. microti* (ATCC 19422), *M. africanum* (ATCC 25420), *M. bovis* BCG (ATCC 19210) were grown for 18-21 days on 7H11 agar plates (Hardy Diagnostics, USA). Four reference species from *M. abscessus* complex *M. abscessus* (ATCC 19977), *M. massiliense* (DSMZ 45103), *M. bolletii* (DSMZ 45149), *M. chelonae* (ATCC 35752) were grown for 4-5 days on 7H11 agar plates. An approximate 0.5 McFarland dilution of all species was prepared and these samples incubated in the MGIT system (BD BACTEC). The protein extract was purified and then subjected to intact protein analysis using a Q Exactive™ HF mass spectrometer (Thermo Scientific) using a rapid gradient liquid-chromatography.

**Results:** The developed assay is simple, rapid, and reliable for discriminating *M. tuberculosis* and *M. abscessus* species complex members. ESI-MS patterns were highly reproducible and the assay identified approx. 70-100 proteoforms with a gradient elution program. Protein masses ranged from 3-30 kDa. Identified proteoforms are unique to individual members of the species complexes.

**Conclusions:** A rapid high-resolution accurate mass spectrometry technique for species-level identification was developed, which is very time efficient, demonstrating promise for more accurate, early diagnosis and reduce treatment costs. Also, provides scope to evaluate many more clinical species in future.

Factors associated with inadequate intravenous colistin dosages: results from a multi-centre, cross-sectional study

Michele Mirabella*1, Daniele Roberto Giacobbe1, Antonio Vena1, Carolina Saffioti2, Matteo Rinaldi3, Angela Raffaella Losito4, Francesca Rafteselli4, Malgorzata Karolina Mikulska1, Maddalena Giannella3, Pierluigi Viale5, Mario Tumbarello4, Matteo Bassetti1

1Ospedale Policlinico San Martino, Genoa, Italy, 2Istituto Giannina Gaslini, Genoa, Italy, 3Alma Mater Studiorum University of Bologna, Bologna, Italy, 4Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: Colistin is a last-resort agent for the treatment of severe infections due to multidrug resistant Gram-negative bacteria (MDR-GNB).

Materials/methods: This is a post-hoc analysis of a multicenter, cross-sectional study, describing colistin use in 22 Italian hospitals (COLI-CROSS study). The primary objective of this post-hoc analysis was to assess factors associated with inadequate intravenous colistin dosage. Inadequate dosage was defined as absence of an adequate loading dose (i.e., 9 million units of colistimethate) and/or absence of adequate maintenance dosages according to the Committee for Medicinal Products for Human Use of the European Medicines Agency, adjusted to renal function. Demographic and clinical variables were tested for their association with inadequate dosage in univariable logistic regression models. Then, variables potentially associated with inadequate dosage in univariable models (p<0.10) were included in an initial multivariable logistic regression model, and further selected for the final model using a stepwise backward procedure.

Results: Overall, 187 patients receiving intravenous colistin were included in the analyses. Their median age was 63 years (interquartile range 49-74), and 60% were males (113/187). Inadequate colistin dosages were administered in 27% of cases (50/187). In multivariable analyses, acute kidney injury (AKI) according to KDIGO criteria (dummy variable with stage 0 as reference, odds ratio [OR] 9.9 with 95% confidence intervals [CI] 1.6-60.2 for stage 1, OR 2.5 with 95% CI 0.3-17.7 for stage 2, OR 2.4 with 95% CI 0.3-21.4 for stage 3, overall p 0.002) and chronic obstructive pulmonary disease (COPD, OR 3.1 with 95% CI 1.3-7.4; p 0.013) were independently associated with inadequate colistin dosage, whereas presence of a central venous catheter (OR 0.4, 95% CI 0.2-0.8, p 0.001) was conversely associated with adequate colistin dosage.

Conclusions: An increased risk of inadequate intravenous colistin dosage was observed in patients with chronic or acute co-morbid conditions, such as COPD and AKI. In particular, the association between AKI and inadequate dosage may reflect the perception of an increased risk of nephrotoxicity in patients with impaired renal function, which nonetheless should not be accompanied by further dosage reductions beyond those recommended and might represent the target of dedicated antimicrobial stewardship efforts.

Risk of infection in patients with carbapenem-resistant Enterobacterales (CRE) rectal carriage: a comparative study of KPC and NDM CRE (CHIMERA Study)

Marco Falcone, Giusy Tiseo, Valentina Galfo, Cesira Giordano, Alessandro Leonildi, Luigi F Saccaro, Enrico Tagliaferri, Simona Barnini, Francesco Menichetti

1University of Pisa, Pisa, Italy

Background: KPC-producing carbapenem-resistant Enterobacterales (CRE) are endemic in several European countries but NDM are becoming more and more frequent. The aim of this study is to identify specific risk factors for nosocomial infections among KPC and NDM-rectal carriers.

Materials/methods: This prospective observational study included patients with CRE rectal carriage admitted to an academic hospital in Italy from January 2019. Rectal swab cultures were performed in all patients at the time of hospital admission and every week thereafter. Molecular analyses on rectal swab specimen were performed using the Xpert Carba-R assay (Cepheid, Sunnyvale, USA). Patients carrying NDM or KPC CRE who developed infection were compared with colonized patients who did not. Infections included urinary-tract infections (UTI), pneumonia, intra-abdominal infections (IAI), ABSSSI, bloodstream infections (BSI). The attack rate of infections caused by the same colonizing CRE were defined as the number of infections divided by the size of the population at risk (rectal carriers). A multivariate analysis to identify risk factors for infection was performed in KPC and NDM-rectal carriers.

Results: 303 patients with CRE rectal carriage were included in the study. Among them, 161 (53.1%) were NDM and 142 (46.9%) KPC-rectal carriers. The most common infections were UTI (12.9%), pneumonia (6.6%), IAI (5.6%), ABSSSI (5%), BSI (8.6%). Attack rates of infections were higher in NDM compared to KPC-rectal carriers (Figure 1). Time from positive rectal swab to infection was shorter among NDM (5 [1-14] days) compared to KPC-rectal carriers (10 [2-15] days, p=0.024). At multivariate analysis, number of colonized sites besides stool (OR 11.948 [5.042-28.315], p<0.001) and intravascular devices (OR 2.843 [1.120-7.214], p=0.028) were factors independently associated with the risk of infection in KPC-rectal carriers. Conversely, urinary-tract diseases, including urinary-stenting or nephrolithiasis, (OR 22.638 [4.144-123.658], p<0.001), number of colonized sites besides stool (OR 4.056 [2.217-7.422], p<0.001), intravascular device (OR 3.115 [1.363-7.121], p=0.007) and steroids (OR 2.771 [1.2-6.395], p=0.017) were independently associated with infection among NDM-rectal carriers.

Conclusions: Patients with NDM-rectal carriage have higher risk of infections compared to KPC-rectal carriage. Although some risk factors for infections are shared in KPC and NDM-rectal carriers, urinary disease was the strongest risk factor among NDM-carriers.

Abstract 5249

Distinguishing clinical characteristics and outcomes in patients with polymicrobial Staphylococcus aureus bacteraemia

Corey Kelsom*1, Emi Minejima2, Karen Tan3, Paul Nieberg1, Annie Wong-Beringer3

1Huntington Hospital, Pasadena, United States, 2University of Southern California School of Pharmacy, LAC-USC Medical Center, Los Angeles, United States, 3University of Southern California School of Pharmacy, Los Angeles, United States

Background: Staphylococcus aureus is a common cause of bacteraemia and is often monomicrobial in nature. However, the clinical significance of polymicrobial S. aureus bacteraemia is not well-studied. We sought to determine clinical characteristics and outcomes that distinguished between patients hospitalized with polymicrobial (P-SAB) and monomicrobial (M-SAB) S. aureus bacteraemia.

Materials/methods: Retrospective chart review of patients ≥18 years old hospitalized with S. aureus bacteraemia from 2014-2019 was conducted. 465 patients were screened for polymicrobial bacteraemia, defined as growth of additional organism(s) besides S. aureus in the same blood culture. P-SAB and M-SAB patients were matched 1:2 by age, gender and bacteremia type (MRSA vs. MSSA). Relevant demographic and clinical data were recorded.

Results: 69 patients were included: 23 P-SAB and 46 M-SAB. Median age (72y), gender (78% male), and ethnicity did not differ between groups. P-SAB patients were more likely to be admitted from a long-term care/skilled nursing facility (52% vs. 24%, p=0.039), whereas M-SAB patients were more likely to be admitted from home (72% vs. 39%, p=0.039). MRSA predominated in P-SAB patients, with source of bacteremia most commonly being pneumonia (22% vs. 7%, p=0.106) and urinary tract infection (26% vs. 4%, p=0.014) in P-SAB group compared to M-SAB group. In the P-SAB group E. faecalis was isolated most frequently (n=6, 26%), followed by K. pneumoniae (n=4, 17%). While length of stay (9d P-SAB vs. 10d M-SAB, p=0.448) and requirement for ICU stay (43% P-SAB vs. 30% M-SAB, p=0.298) did not differ significantly between groups, more P-SAB patients were discharged to LTCF/SNF (70% vs. 39%, p=0.024). P-SAB patients took twice as long to achieve clinical stability (median 8d vs. 4d, p=0.009), although readmission rate (39% P-SAB vs. 41% M-SAB) and 30d mortality (9% P-SAB vs. 7% M-SAB) did not differ.

Conclusions: Healthcare setting exposure (i.e. residence in LTCF/SNF) appears to predispose patients to bloodstream infection with multiple organisms. Polymicrobial bacteremia is associated with high overall healthcare burden as evidenced by prolonged time to reach clinical stability and eventual discharge to LTCF/SNF.

Abstract 5250

Genomic analyses of carbapenem-resistant Klebsiella pneumoniae in Singapore: resistance and virulence determinants

Jocelyn Teo1,2, Cheng-Yee Tang*,2, Shannon Lee1, Tze-Peng Lim1,3,4, Yiying Cai1,5, James Heng Chiak Sim1, Thuan Tong Tan1, Rick Twee Hee Ong6, Andrea Kwa1,4,7

1 Singapore General Hospital, Singapore, Singapore, 2 National University of Singapore and National University Health System, Saw Swee Hock School of Public Health, Singapore, Singapore, 3 SingHealth Duke-NUS Pathology Academic Clinical Programme, Singapore, Singapore, 4 SingHealth Duke-NUS Medicine Academic Clinical Programme, Singapore, Singapore, 5 National University of Singapore, Pharmacy, Singapore, Singapore, 6 Duke-NUS Medical School, Singapore, Singapore

Background: Kp is a versatile organism that can carry/acquire a variety of virulence and resistance genes. Hypervirulent Kp (hvKp) has higher propensity of causing severe diseases than classical Kp. However, there is still a lack of understanding of the contribution of virulence genes in pathogenesis. We characterised the resistance and virulence determinants of CrKp in Singapore and determined if virulence genes were associated with infection and mortality.

Materials/methods: 301 CrKp isolated between 2009-2018 from a Singapore tertiary hospital were subjected to Illumina whole genome sequencing and genotyped using the Kleborate software. Infections were classified according to CDC surveillance definitions. Virulence determinants were compared between isolates causing: (a) colonisation and infection; (b) mortality and no mortality using chi-square/Fisher’s exact tests.

Results: CrKp belonged to 75 different sequence types (ST); ST14 (n=39), ST11 (n=25) and ST16 (n=21) were most prevalent. All were multi-drug resistant and had ≥1 resistant gene [median=11, IQR=7–13]. Carbapenemase genes were detected in 260 isolates, with blaKPC being predominant (n=129), followed by blaoxa48-like (n=73), blaNDM (n=40) and co-producers (n=18). 53 distinct K capsule types were observed. The K1 and K2 capsule types, which are traditionally associated with hvKp, accounted for 3 and 35 isolates respectively. The frequencies of virulence genes were as follows: ybt (n=137), iuc (n=34), iro (n=19), clb (n=16), rmpA (n=17) and rmpA2 (n=26) (Figure 1). Isolates harbouring all 6 virulence genes were either K1 ST23 (n=5) or K2 ST65 (n=7). No virulence genes were detected in 155 isolates. 132 CrKp were implicated in infections, with bloodstream infections (n=60) being the commonest. The proportions of the individual virulence genes in colonisation and infection isolates were largely similar (p>0.05). Of the 12 isolates with all 6 virulence genes, only 7 were infection-causing. 38/132 CrKp resulted in 30-day mortality. No single virulence gene was associated with 30-day mortality (p>0.05).

Conclusions: Our genomic analyses suggest that known virulence determinants are low amongst CrKp in Singapore. There appears to be no clear association with disease severity and known virulence determinants in our population. Further studies are required to identify genetic factors predicting hvKp to inform clinical management.

A widespread toxin-antitoxin system exploiting growth control via alarmone signalling

Sofia Raquel Alves Oliveira*, Steffi Jimmy,2,3 Chayan Kumar,3 Abel Garcia Pino,4 Tatsuaki Kurata3, Alan Koh,5 Albinas Cepauskas,4 Hiraku Takada2,3, Tanel Tenson1, Henrik Strahl3, Konstantine Stavropoulos4, Vasili Hauryliuk2,3, Gemma Catherine Atkinson3

1University of Tartu, Institute of Technology, Tartu, Estonia, 2Umeå University Department of Molecular Biology, Umeå Centre for Microbial Research (UCMR) and The Laboratory for Molecular Infection Medicine Sweden (MIMS), Department of Molecular Biology, Umeå, Sweden, 3Umeå University Department of Molecular Biology, Umeå, Sweden, 4Université Libre de Bruxelles, Cellular and Molecular Microbiology, Faculté des Sciences, Gosselies, Belgium, 5Institute for Cell and Molecular Biosciences Newcastle University, New Castle, United Kingdom

Background: Under stressful conditions, bacterial RelA-SpoT Homologue enzymes synthesise the alarmone \((p)pGpp\), a nucleotide messenger. This alarmone is present in most bacterial species, including major pathogens. \((p)pGpp\) is essential for bacterial pathogens to become virulent, when bacteria face stress-inducing environments during infection. Therefore, the \((p)pGpp\)-mediated signalling is a promising target for the development of antibacterial agents subsequently its regulatory mechanism plays a central role in bacterial virulence and tolerance to antibiotics. We discovered that Small Alarmone Synthetases (SASs) that contain the \((p)pGpp\) synthesis domain, can be part of Toxin-Antitoxin (TA) systems. Here we investigate the distribution of this type of regulatory systems.

Materials/methods: Toxicityneutralisation assays were performed in \(E.\ coli\) BW25113 expressing toxin and antitoxin on LB medium plates with 0.2% arabinose and 1 mM IPTG (induction conditions). Nucleotide pools analysis were performed on HPLC. Cell cultures were grown in defined MOPS medium supplemented with 0.5% glycerol at 37 °C with induction conditions.

Results: We have discovered that multiple SAS subfamilies can be encoded in broadly distributed conserved bicistronic operon architectures in bacteria and bacteriophages that are reminiscent of those typically seen in toxin-antitoxin operons. We have validated five of these SASs as being toxic (toxSASs), with neutralisation by the protein products of six neighbouring antitoxin genes. The toxicity of \(Cellulomonas\ marina\) toxSAS FaRel is mediated by \((p)pGpp\) accumulation combined with depletion of cellular ATP and GTP pools, and this is counteracted by its HD domain-containing antitoxin.

Conclusions: The ToxSAS-antiToxSAS system is a novel TA paradigm comprising multiple different antitoxins that exemplifies how ancient nucleotide-based signalling mechanisms can be repurposed as TA modules during evolution.

Abstract 5260

From DNA to diagnosis: a rapid, next-generation sequencing pipeline for detecting multidrug-resistant *Mycobacterium tuberculosis* mutations

1Longhorn Vaccines and Diagnostics, San Antonio, United States, 2University of Pretoria, Pretoria, South Africa, 3Addis Ababa University, Addis Ababa, Ethiopia, 4Hyrax Biosciences, Cape Town, South Africa

Background: Next-generation sequencing (NGS) has become a routine approach for detection of gene regions known to harbor resistance-conferring mutations in *Mycobacterium tuberculosis* (MTB). We performed a complete MTB DNA-to-diagnosis pipeline using targeted streamlined NGS library preparation coupled with standardized, web-based bioinformatic analysis to deduce antibiotic resistance profiles from a panel of contemporary clinical isolates from South Africa and Ethiopia.

Materials/methods: Clinical isolates were collected and shipped at ambient temperature from Africa to the United States in PrimeStore Molecular Transport Medium® (PS-MTM). After DNA extraction, rapid targeted-PCR library preparation (PrimeSeqTB) and NGS (Illumina MiSeq) were performed. FASTQ files were uploaded using a web-based bioinformatics pipeline (Hyrax Biosciences) and the resulting drug resistance profiles were generated within hours and compared to WGS results obtained using LaserGene (DNAStar) analysis.

Results: A panel of MTB clinical isolates from South Africa (N=16) and Ethiopia (N=20) revealed a variety of antibiotic resistance-conferring mutations. Antibiotic resistance to rifampin, conferred by S-450-L in the *rpoB* gene, and isoniazid, conferred by *katG* mutation at position S-350-T were most frequently reported. However genetic resistance to fluoroquinolone and pyrazinamide, conferred by mutations in the *gyrA* and *pncA* genes, respectively, were also reported. There was concordance in the TB resistance mutations identified by TGS and web-based reporting compared to genetic analysis determined using WGS and DNAStar analysis.

Conclusions: A complete MTB DNA-to-diagnosis system that incorporates laboratory methods for rapid targeted sequencing and a bioinformatics pipeline for standardized reporting of drug resistance data will guide patient care and global surveillance.

**Abstract 5262**

**Adapting technology to provide nationwide testing for highly-resistant infections in the United States: aztreonam-avibactam susceptibility testing of metallo-β-lactamase-producing Enterobacteriaceae**

Sarah Malik*1, Amelia Bhatnagar1, Maria Karlsson1, David Lonsway1, Joseph Lutgring1, Jennifer Huang1, Stephanie Gumbis3, Allison C. Brown1

1Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Goldbelt CG, Juneau, AK, United States, 3Centers for Disease Control and Prevention, Atlanta, United States

**Background:** Metallo-β-lactamase (MBL)-producing Enterobacteriaceae can cause significant morbidity and mortality, largely because treatment options are limited. Aztreonam-avibactam, not approved by the U.S. Food and Drug Administration (FDA) and still undergoing clinical trials, has demonstrated good in vitro activity and case reports indicate successful treatment of MBL-producing Enterobacteriaceae infections. Aztreonam-avibactam can be used to treat these infections by administering aztreonam and ceftazidime-avibactam. In 2019, the U.S. Centers for Disease Control and Prevention (CDC) piloted aztreonam-avibactam antimicrobial susceptibility testing (AST) of MBL-producing Enterobacteriaceae using digital dispensing technology. We describe the problem of MBL-producing Enterobacteriaceae in the United States, the technology used to perform aztreonam-avibactam AST, and the pilot program offering this unique testing.

**Materials/methods:** State and local public health laboratories in the Antibiotic Resistance Laboratory Network (AR Lab Network) characterized carbapenem-resistant Enterobacteriaceae (CRE) isolates by performing organism identification, AST, and PCR-based detection of blaKPC, blaNDM, blaOXA-48-like, blaVIM, and blaIMP carbapenemase genes. Testing results were reported to CDC at least monthly. In March 2019, a subset of AR Lab Network labs adopted the HP D300e Digital Dispenser to create custom broth microdilution (BMD) panels for aztreonam-avibactam AST. Enterobacteriaceae displaying resistance to all β-lactams (including either ceftazidime-avibactam or meropenem-vaborbactam), or those carrying an MBL gene (blaVIM, blaNDM or blaIMP), were eligible for aztreonam-avibactam AST to inform patient treatment decisions. Aztreonam-avibactam AST results were reported to submitters within three working days.

**Results:** From January 2017 to June 2019, the AR Lab Network tested 30,537 CRE isolates. At least one targeted carbapenemase gene was detected in 36% (n=10,838) of CRE tested; 10% (n=1104) of the carbapenemase genes identified encoded MBLs. From March through October 2019, 38 CRE isolates from 17 states were sent for aztreonam-avibactam AST. All confirmed MBL-positive CRE isolates (n=36) tested against aztreonam-avibactam carried the blaNDM gene. Elevated aztreonam-avibactam MICs (>8/4 µg/mL) were detected in 14% (5/36) of MBL-positive isolates tested.

**Conclusions:** Increased testing of CRE by the AR Lab Network has improved our ability to detect MBL-producers. Using digital dispenser technology, we can now perform aztreonam-avibactam AST and inform therapeutic decision making, which may improve patient outcomes for those infected with MBL-producing Enterobacteriaceae.

**Presenter email address:** vgg9@cdc.gov
Antimicrobial combination activity of vancomycin and antimalarial quinacrine against methicillin-resistant Staphylococcus aureus isolated from infected diabetic foot ulcers

Adriana Oliveira Da Silva*1,2,3,4; Damiano Correia1; Vanessa Silva1,2,3,4; José António Carvalho5; Ana Paula Castro6; Gilberto Igrejas2,3,4; Rosa Rego5; Patricia Poeta1,4

1MicroART-Microbiology and Antibiotic Resistance Team, Department of Veterinary Sciences, University of Trás-os-Montes and Alto Douro (UTAD), Vila Real, Portugal; 2Department of Genetics and Biotechnology, University of Trás-os-Montes and Alto Douro (UTAD), Vila Real, Portugal; 3Functional Genomics and Proteomics Unit, University of Trás-os-Montes and Alto Douro (UTAD), Vila Real, Portugal; 4Associated Laboratory for Green Chemistry (LAQV-REQUIMTE), University NOVA of Lisboa, Caparica, Portugal; 5Department of Chemistry and CQ-VR, University of Trás-os-Montes and Alto Douro (UTAD), Vila Real, Portugal; 6Medical Center of Trás-os-Montes e Alto Douro E.P.E., Vila Real, Portugal

**Background:** The emergence of multidrug-resistant pathogens is a major cause of infection-related mortality and poses therapeutic failures that have led to an increase in antimicrobial resistance. Due to a lack of therapeutic options, studies have focused on the combination of antibiotics as an alternative treatment to eradicate these infections and allow, earlier stabilization of patients and decrease the length of antimicrobial therapy. The aim of the study is to determine different combinations of the antibiotic vancomycin (VAN) and an antimalarial, quinacrine (QUI) against MRSA from infected diabetic foot ulcers.

**Materials/methods:** The minimum inhibitory concentrations (MICs) of VAN and QUI against eleven clinical MRSA isolates were determined according EUCAST guidelines (2019). The tests were performed using broth microdilution method on 96-well plates on duplicate. Referring to the MICs of the two agents, checkerboard assay was designed to determine the combinations against the MRSA isolates according to previous method. The following combinations were tested: MICVAN-MICQUI; MICVAN-MICQUI; MICVAN-MICQUI; MICVAN-MICQUI; MICVAN-MICQUI; MICVAN-MICQUI and MICVAN-MICQUI.

**Results:** The MICs of VAN in the eleven MRSA strains were 2 µg/mL for ten strains and 4 µg/mL for one strain. The MICs of QUI were 250 µg/mL for four strains, 500 µg/mL for three strains and 2000 µg/mL for four strains. VAN in combining with QUI showed inhibition of growth in all isolates. When we combined MICVAN and MICQUI there was significant inhibitory effect in 45.7% of the isolates. In combination of MICVAN with MICQUI a large percentage of inhibition of isolates was observed (72.7%), the same did not happen when combined MICVAN with MICQUI in this combination only 45.4% of the isolates inhibited, which suggested that they can be used together. In combinations MICVAN-MICQUI; MICVAN-MICQUI; MICVAN-MICQUI and MICVAN-MICQUI most isolates grew at these concentrations. Relatively to the combination MICVAN-MICQUI varied among strains.

**Conclusions:** The antimalarial quinacrine when combine with vancomycin suggest a relevant synergistic effect against MRSA from infected diabetic foot ulcers. This combination offers a potential option to treating several infections, when conventional therapeutic options are absent.

**Presenter email address:** adrianaa.silva95@gmail.com
Whole genome sequencing of heterochronous isolates of Burkholderia cenocepacia and B. contaminans from two patients with cystic fibrosis using Nanopore and Illumina platforms

Anne-Marie Bernier*1, Shari Tyson1, Tamara Burdz2, DeborahWiebe1, Kathy Bernard2

1Université de Saint-Boniface, Winnipeg, Canada, 2National Microbiology Laboratory, Public Health Agency of Canada, Winnipeg, Canada

Background: Burkholderia cenocepacia and Burkholderia contaminans are members of the environmentally-derived Burkholderia cepacia complex which can be opportunistic pathogens causing chronic lung infections particularly in cystic fibrosis patients. The objective of this study was to use whole genome sequencing of heterochronous isolates from two patients to evaluate the genomic changes occurring in these pathogens during chronic infection of human hosts.

Materials/methods: Six strains of B. cenocepacia (ST28) isolated over 8 years from the same patient, and eight isolates of B. contaminans (ST482) taken over 4 years from the same patient were investigated. STs were determined by traditional MLST. The initial strain from each patient was sequenced using both MinION (Oxford Nanopore) and NexteraXT (Illumina, MiSeq) DNA libraries to generate long read and hybrid assemblies. These reference chromosomes were circularized and polished. Draft genomes for the remaining heterochronous isolates were assembled from Illumina MiSeq reads using SPAdes. Annotation was done using Prokka. Single nucleotide variants and insertions/deletions (indels) were identified using SNVPhyl and Snippy workflows and phylogenetic trees were produced. Phaster was used to identify phage, and MICs were assessed according to CLSI guidelines. Antimicrobial resistance genes were identified using the Comprehensive Antimicrobial Resistance Database (CARD).

Results: All strains were multidrug resistant, with MICs to several antimicrobials increasing over time. Genes encoding aminoglycoside, fluoroquinolone and tetracycline efflux pumps were identified in all strains of both species. The B. cenocepacia strains harboured three phages, and the complete genome consisted of three circular chromosomes and one plasmid with a total of 7.9 Mb, 7279 CDS and a G+C content of 67%. The complete genome of B. contaminans consisted of three circular chromosomes and two plasmids with a genome size of 8.6 Mb, 7781 CDS and a G+C content of 66.4%. All strains of B. contaminans harboured one intact phage. Comparative genomics identified a progressive increase in the number of indels and snps over the course of time in both species.

Conclusions: Complete whole genomes of B. cenocepacia and B. contaminans will allow us to gain insight into the changes that occur during chronic lung infections of cystic fibrosis patients.

Abstract 5266

Whole genome sequencing to investigate genetic diversity in HBeAg-positive and HBeAg-negative hepatitis B virus infection

Anna Mcnaughton1, Mariateresa De Cesare2, Louise Downs3, Jolynne Mokaya1, Joshua B. Singer4, Sreenu Vattipally5, David Bonsall5, M. Azim Ansari2, Oliver E. Amin6, Mala Maini6, Philippa Matthews1,3

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2University of Oxford, Wellcome Centre for Human Genetics, Oxford, United Kingdom, 3Oxford University Hospitals NHS Foundation Trust, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom, 4University of Glasgow, MRC Centre for Virus Research, Glasgow, United Kingdom, 5University of Oxford, Big Data Institute, Oxford, United Kingdom, 6University College London, Division of Infection and Immunity, London, United Kingdom

Background: Hepatitis B virus (HBV) e-antigen (HBeAg) is a short, secretory protein encoded by pre-Core (pre-C), typically expressed early in infection. HBeAg has immunomodulatory properties, inducing host tolerance to HBV, resulting in conserved viral populations and high viral loads. During HBeAg seroconversion, the immunomodulatory effect of HBeAg declines and increased immune selection pressures are exerted on the viral population, with potential impact on clinical endpoints (clearance, transmission and liver disease). To investigate the impact of these varying immune environments, we performed HBV sequencing on HBeAg-positive and HBeAg-negative adults with chronic HBV (CHB) infection.

Materials/methods: Blood samples from a heterogeneous cohort of HBeAg-positive (n=11) and HBeAg-negative (n=18) CHB patients were collected from hospital clinics in London, UK. DNA was extracted and sequencing libraries prepared (Nextera). Samples were pooled and underwent a whole genome (WG) target enrichment approach with Illumina. Data were analysed using a pipeline based on the GLUE platform (http://glue-tools.cvr.gla.ac.uk/).

Results: Viral loads were higher among HBeAg-positive patients (median 6.3log10 IU/ml, IQR 5.6-7.5log10 IU/ml) than in HBeAg-negatives (median 5.0log10 IU/ml, IQR 4.3-5.7log10 IU/ml) (p=0.006). WG sequences were returned for 11/11 HBeAg-positive patients and 17/18 HBeAg-negative patients, representing genotypes A, B, C, D and E. Median coverage was higher in HBeAg-positive (1530 read/site) than HBeAg-negative samples (394 reads/site) (p<0.001). 10/11 HBeAg-positive and 14/18 HBeAg-negative samples with median coverage ≥50 reads/site were included in a comparative analysis of intra-host diversity. Median diversity was higher in the HBeAg-negative samples (p<0.001). Highly polymorphic sites (Shannon entropy score >0.4) were more common in HBeAg-negative samples (median 11 sites/sequence) than HBeAg-positive samples (median 2 sites/sequence). In HBeAg-positive samples, 61% of highly polymorphic sites were located in pre-S1, pre-S2 or S compared with just 37% in HBeAg-negative samples (p=0.01) [see Figure].

Conclusions: Highly polymorphic sites are more common in HBeAg-negative samples, in which they are distributed widely throughout the genome. Deep sequencing can provide insight into the changing host-viral interplay during different phases of CHB infection, with potential to inform better understanding of immune responses, pathophysiology, and therapeutic interventions.

Figure: Location of highly polymorphic sites in the HBV genome in HBeAg-positive (n=10) and HBeAg-negative patients (n=14).

A One Health approach identifies the environment surrounding food animals as a potential reservoir of blaCTX-M genes in the community in Vietnam

Minh Nguyen Ngoc*1, Ha Thi Thu Hoang2, Basil Britto Xavier1, Christine Lammens1, Thi Bich Ngoc Hoang3, Hai Le Thanh3, Ngoc Thi Pham3, Anh Dang Duc3, Herman Goossens1,5, Surbhi Malhotra-Kumar1

1Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, University of Antwerp, Antwerpen, Belgium, 2National Institute of Hygiene and Epidemiology, Hanoi, Vietnam, 3National Pediatric Hospital, Hanoi, Vietnam, 4National Institute of Veterinary Research, Hanoi, Vietnam, 5University Hospital Antwerp, Edegem, Belgium

Background: The global emergence of extended-spectrum beta-lactamase-producing Escherichia coli (ESBL-E) is a significant threat to public health. In context of a “One Health” approach, we investigated the prevalence and transmission dynamics of blaCTX-M-carrying ESBL-E (blaCTX-M-E) isolated from patients, food-animals, their carcasses, and the slaughterhouse environment in Hanoi, Vietnam.

Materials/methods: During 2014-2015, we collected samples from patients with uncomplicated urinary tract infections (n=2,015), pigs and chickens from farms and slaughterhouses (n=365), and environmental samples in slaughterhouses (surface and wastewater, n=78) all within a 20-33 km radius from each other. UriSelect-4 (Biorad, USA) and MacConkey agars were used to identify ESBL-E from the collected samples. Antimicrobial susceptibility to 16 antibiotics was tested using Vitek, E-test (BioMérieux, France), and macro-broth dilution; results were interpreted according to the CLSI-M100-S29 guideline. Strains were typed by multi-locus sequence typing and screened for blaCTX-M genes by PCRs. blaCTX-M-E strains were subjected to 2x250bp paired-end plasmid sequencing (Miseq, Illumina Inc., USA). Additionally, 15 strains were selected for multiplexed long-read sequencing (MinION, Oxford Nanopore, UK).

Results: A total of 225 ESBL-E and 198 blaCTX-M-E strains were identified. Approximately 97% of blaCTX-M-E strains were multi-drug-resistant (MDR), including resistance to colistin (15%, n=29) and carbapenems (3%, n=5). From the different sample sources, we identified high clonal diversity and 8 blaCTX-M variants belonging to two CTX-M groups: CTX-M group 1 (blaCTX-M-1, blaCTX-M-11, blaCTX-M-15, blaCTX-M-55) and CTX-M group 9 (blaCTX-M-14, blaCTX-M-24, blaCTX-M-27, blaCTX-M-65) (Figure A). ST1193 and ST155 were dominant clones carrying blaCTX-M-27 and blaCTX-M-55 in humans and in animals, respectively. Utilizing long-read sequencing, we identified highly similar IncFII plasmids carrying blaCTX-M-55 in a lairage surface swab from a pig slaughterhouse and a human sample collected almost 2 years later. Moreover, identical fusion IncN-IncHI2 plasmids carrying blaCTX-M14 were commonly identified in a water sample collected from a chicken slaughterhouse and a chicken carcass swab from another slaughterhouse 16 km away (Figure B).

Conclusions: Our study emphasised high prevalence of MDR ESBL-E across sample sources in Vietnam. While no direct transmission routes could be established, we show the potential role of the slaughterhouse environment as an intermediate reservoir for dissemination of blaCTX-M-carrying plasmids.
Figure. (A) Prevalence of of \textit{bla}_{CTX-M} \ genes distributed between sample sources. (B) Potential transmission of \textit{bla}_{CTX-M} \ genes between sample sources identified by long-read sequencing; red arrows represents sharing plasmids between sample sources

Modulation of the immune status in pyelonephritis caused by *Pseudomonas aeruginosa* in children with hydronephrosis

Malanchuk Svitlana*1, Mishyna Maryna2, Iryna Marchenko2, Vyacheslav Davydenko2, Yuliya Mozgova2

1V.N. Karazin Kharkiv National University, Kharkiv, Ukraine, 2Kharkiv National Medical University, Kharkiv, Ukraine

**Background:** Among kidney diseases in children, the leading place occupied by hydronephrosis, which developed against the background of urinary tract obstruction and complicated by pyelonephritis. The purpose of the study was to identify immunological features of pyelonephritis due to *Pseudomonas aeruginosa* in children with hydronephrosis.

**Materials/methods:** The determination of T- and B- subpopulations performed by immunofluorescence reaction (RIF). The phagocytic activity of neutrophils investigated for its ability to absorb polystyrene latex particles. Cytokine levels (IL - 1, TNF-α) and IgM and IgG were determined by ELISA. The metabolic activity of neutrophils evaluated in the nitroblue tetrazolium restoration (NTR test) using light microscopy.

**Results:** Studies have shown pronounced changes of immunological reactivity parameters in pyelonephritis due to *Pseudomonas aeruginosa* in children with hydronephrosis in the active stage of the disease. Shifts in the indices of the cellular component of immunity manifested as a decrease in the relative number of T-lymphocytes with an increase in the absolute number of T-cells. In addition, the relative number of CD4-lymphocytes and immunoregulatory index CD4/CD8 were decreased, and shifts in the indicators of the humoral immunity, as a decrease in the relative and absolute number of B-lymphocytes, a low level of IgG and a high level of IgM, an increase in the concentration of CIC (circulating immune complexes). At the same time, were present signs of decrease of nonspecific antibacterial resistance as a low neutrophil activity index, decreased phagocytic number and the RNT (restoration of nitroblue tetrazolium) test, but high level of pro-inflammatory cytokines (IL-1β and TNF-α).

A research results showed that after the use of complex therapy with an immunomodulatory, was detected a higher relative number of CD4 lymphocytes IgG level and indicators of phagocytic activity, a decrease in the concentration of CIC, lower levels of IL-1β and TNF-α in serum.

**Conclusions:** Thus, it was noticed that complex treatment with immunomodulating therapy of pyelonephritis caused by *Pseudomonas aeruginosa*, in children with hydronephrosis, led to normalization of indicators of cellular and humoral immunity, nonspecific resistance and levels of pro-inflammatory cytokines in the blood serum with subsequent normalization of immunological reactivity parameter.

Performance of the NTM Elite agar for the detection of non-tuberculous mycobacteria in sputum samples of patients with cystic fibrosis

Emmanuel Andre*, Lise Raymaekers¹, Susanne Deiwick², Johanne Gafsi³, Pascal Robert Van Bleyenbergh⁴, Lieven Dupont⁴, Barbara C. Kahl², Natalie Lorent⁴

¹Laboratory of Clinical Bacteriology and Mycology, Department of Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium, ²University Hospital Muenster, Institute of Medical Microbiology, Muenster, Germany, ³bioMérieux, Global Clinical Affairs, Marcy l’Etoile, France, ⁴Pulmonology Department, KU Leuven, Leuven, Belgium

Abstract third-party references: Investigational Use Only. Performances establishment ongoing Sponsored by bioMérieux

Background: Nontuberculous mycobacteria (NTM) are emerging pathogens among people with cystic fibrosis (CF). Particularly Mycobacteroides abscessus has been associated with accelerated clinical decline. Nevertheless, NTM colonization and infection is under-reported due to other bacteria resisting the NALC-NaOH decontamination used prior to conventional mycobacterial cultures, possibly resulting in masking of NTM. The NTM Elite agar [bioMérieux, France] is a novel selective agar aiming to facilitate the culture of NTM without prior decontamination of sputum samples.

Materials/methods: We performed a prospective, multi-center study to compare the performance of NTM Elite agar with conventional culture methods for mycobacteria including Löwenstein-Jensen (LJ, bioMérieux, France) and Bactec MGIT (Becton Dickinson, USA). NALC-NaOH decontamination method was used prior to culture on LJ and in MGIT, while sputum samples were inoculated on the NTM Elite agar directly or after non-selective fluidization. Compared to MGIT and LJ which are incubated at 35-37°C, NTM Elite plates are incubated at 30°C, under which conditions the growth of M. tuberculosis is inhibited. This new medium can therefore be incubated and processed in conventional level 2 biosafety conditions.

Results: These preliminary results are based on 153 sputum samples from 117 patients. NTM Elite agar allowed to recover 8 positive NTM cultures (5 M. chelonae, 1 M. abscessus, 1 Mycobacterium avium, 1 other NTM), compared to 3 positive cultures for MGIT (1 M. chelonae, 2 M. avium), and no positive cultures with the LJ medium. Overall, 12% of cultures on NTM Elite agar presented an overgrowth with other micro-organisms, while this proportion was 40% on MGIT and 56% on LJ.

Conclusions: NTM Elite agar, a mycobacterial culture agar which does not require prior NALC-NaOH decontamination, outperforms conventional mycobacterial culture methods for the recovery of NTM from the sputum of CF patients. Therefore, this new medium may be considered as a suitable alternative to current time-consuming methods which still need to be considered when tuberculosis is suspected, and which are typically performed in strict level 3 biosafety conditions, what is not required for working with NTM.

Background: Salmonella enterica serovar Kentucky sequence type (ST) 198 resistant to ciprofloxacin (CipR) has emerged as a global food-borne human pathogen, posing a threat to public health. In the present study, whole genome sequencing (WGS) was applied to characterize CipR S. Kentucky isolates from Spain.

Materials/methods: Ten CipR S. Kentucky isolates were recovered between 2009 and 2018 from patients attended at hospitals in northern Spain and primary care centers associated with them. Susceptibility to antimicrobial agents was determined by automated minimal inhibitory concentration (MIC) and/or disk diffusion assays, and results were interpreted according to CLSI guidelines. Genome sequencing was performed with Illumina in a HiSeq 1500 to generate 2x125 bp paired-end reads. Serotyping, MLST, identification of resistance genes and plasmid analysis were performed with “on line” bioinformatic tools. A phylogenetic tree based on SNPs in the core genome was constructed with RAxML.

Results: All CipR isolates detected were ST198 and carried point mutations in the quinolone resistance-determining regions (QRDRs) of both gyrA (resulting in Ser83Phe and Asp87Tyr or Asp87Asn substitutions in GyrA) and parC (Thr57Ser and Ser80Ile substitutions in ParC). Resistances to other antibiotics [ampicillin, amoxicillin-clavulanic acid, chloramphenicol, aminoglycosides, sulfonamides and tetracycline], arranged in different combinations, and mediated by blaTEM-1B, cmlA1, aac(6)-Iaa, aac(3)-Id, aph(6)-Ia, sul1, tet[A] and tet[C], were also observed. Although plasmids were found in some of the isolates, all resistance genes were chromosomally located. The observed diversity of resistance genes, together with preliminary characterization of the chromosomal regions, supports the existence of different variants of Salmonella genomic island-1 (SGI1). Phylogenetic analysis revealed a close relationship of the S. Kentucky isolates from Spain with S. Kentucky ST198 CipR isolates from other countries. Finally, consistent with the African origin of the clone, travel to Africa was documented for three of patients.

Conclusions: Detection of the epidemic CipR S. Kentucky ST198 clone in Spanish hospitals is a cause of concern, which warranted further surveillance as well as implementation of control strategies to limit further spread. WGS has provided comprehensive information on the antimicrobial resistance genes of the isolates, and is presently being used to determine their virulence gene content.

Interest of follow-up imaging examinations in patients with pyogenic vertebral osteomyelitis: a retrospective study

Sophie Hecquet\textsuperscript{1}, Frank Verhoeven\textsuperscript{1}, Clement Prati\textsuperscript{1}, Daniel Wendling\textsuperscript{1}, Catherine Chirouze\textsuperscript{1}, Kevin Bouiller*\textsuperscript{1}

\textsuperscript{1}Centre hospitalier régional universitaire de Besançon, Besançon, France

**Background:** Pyogenic vertebral osteomyelitis (PVO) represents 2 to 4\% of osteo-articular infections and their incidence is steadily increasing. Magnetic Resonance Imaging (MRI) is currently the most efficient technique for diagnosis. No recommendations are established for monitoring PVOs, particularly in imaging. Although some recommend the use of systematic imaging, its use is controversial.

**Materials/methods:** We conducted a retrospective cohort analysis of patients with PVO who had both baseline and follow-up imaging results available in a French university hospital during the period of 2010-2018. We have classified the follow-up images into two groups, improvement/stability and deterioration, compared with the baseline findings. For each patient, we compared their imaging follow-up to their clinical-biological condition assessed at the same time.

**Results:** We have collected 95 patients. The median age was 68 years, 58 men, 21 patients had a history of spinal surgery. The most frequently reported germ was methicillin-sensitive \textit{Staphylococcus aureus} and the level of spinal involvement was predominantly lumbar. At diagnosis, 95 images were performed, including 26 Computerized Tomography (CT) and 69 MRI. We identified 105 follow-up images, 73 MRIs, 32 CTs. The median delay of realisation was 82 days. Of the 35 patients with clinical and biological recovery, 23 patients (66\%) showed improved imaging and 12 patients (34\%) showed radiological worsening [new abscesses \(n=4\), extension of soft tissue infiltration \(n=2\) and/or epiduritis \(n=2\) or appearance of new locations \(n=1\)]. Among the 50 patients considered as unhealed, on the contrary, imaging shows an improvement in radiological lesions in 39 patients (78\%) and an aggravation in 11 patients (22\%) [new abscesses \(n=4\), extension of soft tissue infiltration \(n=1\) and/or epiduritis \(n=3\) or appearance of new localisations \(n=1\)].

**Conclusions:** Our study showed that there was no correlation between the clinical condition of patients and their follow-up imaging in the context of PVO. Clinical and biological evaluation seems sufficient to determine whether or not the patient is cured. Many images are made during the follow-up with a questionable cost/effectiveness ratio. A standard radiograph may be sufficient to provide a basic structural condition at the end of antibiotic therapy.

Evaluation of integrase strand transfer inhibitors on weight gain and body mass index
Melissa Badowski*1, Rachel Goldberg2, Alexandra Kania2, Thomas Chiampas2, Mahesh Patel3, Sarah Michienzi2

1University of Illinois Hospital & Health Sciences System, College of Pharmacy, Chicago, United States. 2University of Illinois Hospital & Health Sciences System, Chicago, United States, 3University of Illinois Hospital & Health Sciences System, Chicago, United States

Background: Recent data has linked integrase strand transfer inhibitors (INSTIs) to weight gain. Correctional facilities provide the ideal setting to evaluate the true effect on INSTIs on weight gain and BMI since they are controlled environments with consistent medication access.

Materials/methods: A retrospective cohort study evaluated incarcerated adults receiving HIV telemedicine care in 26 prisons in Illinois, USA, from 1/1/2011-12/31/2018. Included subjects were living with HIV/AIDS, receiving stable [i.e. ≥6 months] antiretroviral therapy [ART], virologically suppressed, and had weight monitoring ≥6 months prior and post INSTI switch. Subjects were excluded if previously on INSTIs, ART-naïve, released before 6 months of weight monitoring, reincarcerated, or in segregation. The primary objective was to evaluate average weight change [kg] of INSTIs [bictegravir, dolutegravir, elvitegravir, raltegravir] from baseline. Secondary objectives assessed change in body mass index (BMI) and BMI categorization for all INSTIs. Statistical analysis included Paired Student t-test and descriptive statistics.

Results: Among 117 individuals analyzed, 87% were Black men with an average age of 42.3 years. On average, subjects were stable on ART for 45.4 and 17.2 months prior and post INSTI switch, respectively. All INSTIs were significantly associated with weight gain and increased BMI (Table 1). No significant difference in change in weight or BMI was observed based on baseline regimen (NNRTI [p=0.3208] or PI-based [p=0.7960]), suspected or documented resistance [p=0.0939], single versus multiple tablet regimens [p=0.7469], tenofovir formulation [p=0.1864], or tenofovir disoproxil fumarate (TDF) versus non-TDF use [p=0.1864].

Conclusions: All INSTIs were associated with significant increases in weight and BMI in virologically suppressed patients. Dolutegravir was associated with the highest weight gain while raltegravir was associated with the lowest in this controlled population. Future research should assess long-term impacts of weight gain on morbidity and mortality.

Perspective of the phage mini-antibodies for virus detection by using electro-acoustic sensor

Olga Karavaeva1, Olga Guliy1, Boris Zaitsev2, Irina Borodina2

1Institute of Biochemistry & Physiology of Plants & Microorganisms RAS, Saratov, Russian Federation, 2Kotelnikov Institute of Radio Engineering and Electronics, Russian Academy of Sciences, Saratov Branch, Saratov, Russian Federation

Abstract third-party references: This work was partially supported by the Russian Foundation for Basic Research [grants № 19-07-00300 and 19-07-00304].

Background: Viruses of bacteria are an excellent natural material for the investigation of polyvalent interactions with specific phage mini-antibodies. This is the promise basis for the development of new systems for the detection of viral particles and is of great practical importance, since today viral infections are a global problem. Furthermore the development of new methods for detection of bacterial viruses in various samples, which can provide a result in a short time, is important.

Materials/methods: Obtaining the phage mini-antibodies to bacteriophages from Azospirillum lipoferum Sr65 (FAl-Sp59b) as example, and their use for detection of viral particles by using the developed acoustic sensor. All experiments were conducted by specially manufactured sensor based on a resonator with a lateral electric field in the frequency range 6 - 7 MHz. An approximate criterion for the specific interaction between bacteriophages and mini-antibodies in the analyzed suspension can be defined as follows: the change in the modulus of electrical impedance of the sensor should not be less than ~5% after the addition of a certain number of mini-antibodies to bacteriophage suspension.

Results: The possibility of detecting bacteriophages using phage mini-antibodies by the electro-acoustic analysis method using bacteriophages FAl-65 was shown. It was found that the frequency dependence of the real and imaginary parts of the electrical impedance of a resonator with a suspension of phages and the appropriate antibodies significantly differed from that of the resonator with a control virus suspension without addition of mini-antibodies. The amount of FAl-Sp59b bacteriophage in the analyzed suspension varied from 10^10 to 10^6 phage/mL and the analysis time was not longer than 5 min. The change in the real or imaginary parts of the electrical impedance at the fixed frequency near the resonance after addition of specific mini-antibodies in the suspension can be used as an optimal parameter to obtain the reliable information.

Conclusions: These results demonstrate the possibility of recording the interaction of bacteriophages with mini-antibodies and serve as the basis for the development of a biological sensor for the identification and detection of viruses directly in the liquid phase.

Abstract 5286

**Progress towards the targets for the elimination of viral hepatitis in the European Union**

Erika Duffell*1, Antons Mozalevskis2, Teymur Noori1

1European Centre for Disease Prevention and Control, Stockholm, Sweden, 2Communicable Diseases Department, Division of Health Emergencies and Communicable Diseases, Regional Office for Europe, World Health Organization, Copenhagen, Denmark

**Background:** The concept of elimination for viral hepatitis is based on global targets for reducing the incidence of chronic infections by 90% and attributable mortality by 65% by 2030. The European Centre for Disease Prevention and Control (ECDC) developed a monitoring system to support European Union (EU)/European Economic Area (EEA) Member States (MS) assessing progress towards elimination.

**Materials/methods:** Key indicators relevant for monitoring hepatitis B and C across EU/EEA MS were identified in consultation with an expert advisory group. Mapping of the indicators and sources of data was undertaken to identify existing validated sources of data and gaps where data would need to be collected from countries. ECDC developed a data collection tool to collect data directly from national authorities and data were collected and validated in 2018/9.

**Results:** Data on the indicators were incomplete, with only two countries providing data for all stages of the continuum of care for hepatitis B and ten countries for hepatitis C. Hepatitis related mortality is estimated to be 68,000 in 2015 with increasing trends in mortality rates due to hepatocellular carcinoma but decreasing rates from cirrhosis (all trends not significant). For hepatitis B, 25% (3/12) countries with data achieved the 2020 target of having 50% of persons with chronic infection diagnosed and for hepatitis C, 43.8% (7/16) of countries with data achieved the target. One country of the six with data achieved the target of having over 75% of the diagnosed patients with chronic hepatitis B on treatment but none of the 13 countries reporting hepatitis C data had reached the target.

**Conclusions:** Significant gaps in the availability of data in relation to the prevention, testing and treatment of hepatitis B and C in EU/EEA Member States present a major challenge towards being able to monitor progress towards the targets of elimination. Despite these gaps, available data indicate that countries need to significantly scale up prevention, testing and treatment programmes to impact on incidence and mortality. In order to guide national responses, countries should prioritise improving the quality of their monitoring systems, especially data along the continua of care.

**Presenter email address:** erika.duffell@ecdc.europa.eu
Risk of failure in dual vs. triple therapy in naive HIV patients: a meta-analysis

Antonio Russo1,2, Mariantonietta Pisaturo3, Lorenzo Onorato1, Salvatore Martini1, Simona Signoriello1, Paolo Maggi1, Nicola Coppola1

1University of Campania Studies “Luigi Vanvitelli”, Napoli, Italy

Background: The objective of this meta-analysis is to evaluate the relative risk of failure of two-drug therapies compared to three-drug therapies in HIV-naive patients.

Materials/methods: A systematic review and meta-analysis conducted using MEDLINE Google Scholar and the Cochrane Library. All studies included had to fulfill the following inclusion criteria: present original data from randomized or non-randomized trials; investigate in antiviral therapy-naive HIV subjects the efficacy of a conventional triple ARV [control group], versus a dual ARV [experimental group]; report the primary outcomes clearly defined as regimen failure; report data allowing the odds ratio estimates of relative risk [RR] to be calculated for the different outcomes of therapy with triple versus dual therapy; be published from January 2007 up to January, 2019.

Results: Thirteen studies, from a total of 4,743, meet the inclusion criteria allowing a meta-analysis of 5,205 patients. The meta-analysis performed on study presenting data at 48 weeks, 10 studies, 3495 patients, reveals: in study without maraviroc-based therapy at 48 weeks, the RR of treatment failure [TF] in 6 study on 2428 patients was 1.14 [95%CI: 0.91-1.44]; the RR of virological failure [VF] in 4 studies on 2132 patients was 1.69 [95%CI: 0.96-2.96]. The RR of adverse drug reaction leading to discontinuation of regimen at 48 weeks in 8 study, on a total of 3204 patients, was 0.78 [95%CI: 0.52-1.17]. In patients with less of 200 CD4+, the RR of TF in 2 studies without MRV on 172 patients, was 2.09 [95%CI: 1.09-4.39]; in patients with equal or greater than 200 CD4+, the RR of TF in 2 studies without MRV on 1467 patients, was 1.06 [0.74-1.52]. Regarding the studies at 96 weeks, the RR of TF in 2 papers on 1558 patients, was 1.08 [95%CI: 0.84-1.39]; the VF in 2 papers on 1558 patients, was 1.05 [95%CI: 0.82-1.33].

Conclusions: Dual therapy, excluding those based on maraviroc, are as effective as those with three drugs, showing no difference according different dual therapy, except in patients with less than 200 CD4.

Abstract 5292

**Systematic review on estimated rates of nephrotoxicity and neurotoxicity in patients treated with polymyxins**

Florian Wagenlehner*1, Ersilia Lucenteforte2, Federico Pea3-4, Jason Pogue1, Alex Soriano5, Lara Tavoschi1, Victoria Steele6, Anne Henriksen9, Christopher Longshaw9, Davide Manissero10,11, Raymond Pecini12

1Clinic for Urology, Pediatric Urology and Andrology, Justus-Liebig-University, Giessen, Germany, 2Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, 3Department of Medicine, University of Udine, Udine, Italy, 4Institute of Clinical Pharmacology, SM Misericordia University Hospital, ASU10D, Udine, Italy, 5Department of Clinical Pharmacy, University of Michigan College of Pharmacy, Ann Arbor, United Kingdom, 6Infectious Diseases Department, Hospital Clinic of Barcelona, University of Barcelona IDIBAPS, Barcelona, Spain, 7Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, 8Ashfield Healthcare Communications, Macclesfield, United Kingdom, 9Shionogi BV, London, United Kingdom, 10University College of London, Institute for Global Health, London, United Kingdom, 11Shionogi BV [former employee], London, United Kingdom, 12Shionogi Inc, Florham Park, United Kingdom

Abstract third-party references: Supported by Shionogi D.V.

**Background:** A systematic review was conducted to explore the incidence of nephrotoxicity and neurotoxicity from polymyxin treatment and whether any factors influence these.

**Materials/methods:** Searches of Pubmed and EMBASE were undertaken on 17 June 2019 to identify randomised controlled trials, cohort studies and case-control studies reporting nephrotoxicity and/or neurotoxicity rates in hospitalised patients with infections treated with polymyxins. Where appropriate, raw data of event numbers were pooled and analysed using a random-effects model. Subgroup analyses were performed using mixed effects models. The protocol is registered on PROSPERO (CRD42019134926).

**Results:** Data from 223 studies (29,729 patients) contributed to nephrotoxicity analyses. Across all studies, the rate of nephrotoxicity was 27.6% [95% CI 25.1–30.3%]. When restricted to studies using internationally recognised criteria for nephrotoxicity (AKIN, KDIGO or RIFLE), the rate was 37.8% [95% CI 35.0–40.8%], higher than studies using other criteria [15.4% [95% CI 12.7–18.5%]; p<0.001]. In a meta-analysis of head-to-head studies, polymyxins were associated with a higher rate of nephrotoxicity than non-polymyxin-based comparators (odds ratio 1.962 [95% CI 1.321–2.914]; p=0.001). Subgroup analyses showed that nephrotoxicity rate was significantly affected by polymyxin (polymyxin B: 33.1%; colistin: 26.9%; p=0.026), administration route [inhaled: 15.4%; intravenous: 37.0%; intravenous plus inhaled: 27.8%; p=0.001], dose [low: 26.1%; normal: 32.7%; high: 43.3%; p=0.006] and patient age [neonates: 7.6%; paediatrics: 10.1%; younger adults: 30.4%; older adults: 45.0%; p<0.001], but was unaffected by use of a loading dose [p=0.584], ICU setting [p=0.337], sex [p=1.000] or baseline renal impairment [p=0.145]. Nephrotoxicity rates varied by concomitant nephrotoxin [p=0.004] and were highest in patients receiving vasoressors, diuretics or glycopeptides. Cumulative nephrotoxic effects were observed with multiple nephrotoxins [p=0.001].

Seventy studies (5,464 patients) contributed to neurotoxicity analyses. The overall neurotoxicity rate was 2.9% [95% CI: 2.0–4.3%] and was not significantly affected by polymyxin type [p=0.480]. Across head-to-head studies, polymyxins were associated with a numerically, but not significantly, higher rate of neurotoxicity than non-polymyxin-based comparators [odds ratio 3.906 [95% CI 0.996–15.331]; p=0.051].

**Conclusions:** Polymyxin therapy is associated with a greater risk of nephrotoxicity than other therapies. Further data are required to confirm whether polymyxins are associated with neurotoxicity.

Evaluation of the NeuMoDx HPV assay
Bart Hesselink*1, Saskia Doorn1, Chris Meijer1, Danielle Heideman2, Elizabeth Craig3, Jessica Zhu3, Sundu Brahmasandra3

1Self-screen, Amsterdam, Netherlands, 2Amsterdam UMC, Pathology, Amsterdam, Netherlands, 3NeuMoDx Molecular, Ann Arbor, United States

Background: High-risk human papillomavirus (HPV) testing provides better protection against cervical cancer compared to cytology. Consequently, cervical screening by primary HPV testing has or will be implemented in multiple countries or regions thereof. This emphasizes the need for robust, high-throughput HPV testing solutions. The QIAscreen HPV PCR Test is a clinically validated CE-IVD in vitro real-time PCR-based assay for the qualitative detection of HPV DNA, targeting the E7 region of 15 HPV genotypes (i.e., 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, 67 and 68) and provides separate genotype information for HPV16 and HPV18. Implemented on the fully automated, random access NeuMoDx Molecular System in a high throughput, “sample to result” manner, the NeuMoDx HPV Assay enables significant improvements to the HPV testing workflow. This study reports on the analytical and clinical performance of the NeuMoDx HPV Assay.

Materials/methods: The following analytical performance metrics of the NeuMoDx HPV Assay were studied: limit of detection (LoD) of each genotype, specificity against non-target organisms, reproducibility, and impact of interfering substances. Agreement and clinical performance for CIN2+ was determined against a reference assay on 253 cervical scrapes collected in PreservCyt™ collection media, comprising 63 cases (CIN2+) and 190 controls (≤CIN1).

Results: All the reagents and consumables used for the NeuMoDx HPV Assay are stable at ambient conditions and have ready-to-use configurations requiring no user mediated steps. The LoD of the NeuMoDx HPV Assay was determined to be equivalent or better than the reference QIAscreen HPV PCR Test. No cross-reactivity was observed against relevant non-target microorganisms. No interference was demonstrated in the presence of endogenous and exogenous interfering moieties as well as commensal organisms. Turnaround time for the complete test was ~60 minutes, with no user monitoring required once the samples and reagents were loaded. Agreement on clinical specimens was 96.4% (244/253; kappa value 0.93) compared to reference and relative clinical sensitivity and specificity for CIN2+ were both 98%.

Conclusions: The NeuMoDx HPV Assay as implemented on the NeuMoDx Molecular System is a rapid, easy to use, and effective test for detection of high-risk HPV with HPV16 and HPV18 genotype information from cervical scrapes.

Impact of pretransplant norfloxacin prophylaxis on multidrug-resistant post–liver transplant infections

1Hospital Universitari Vall d’Hebron, Barcelona, Spain, 2Hospital Universitari Bellvitge, Hospital de Llobregat, Spain

Background: Bacterial infections are major causes of morbidity and mortality after liver transplantation (LT). We are currently facing a progressive increase in the rate of MDR microorganisms. Norfloxacin is widely used for the prophylaxis of spontaneous bacterial peritonitis. The effect of norfloxacin on post-LT MDR infections is unknown. The aim of our study was to determine the effect of norfloxacin prophylaxis on MDR infections within the first 30 days after LT.

Materials/methods: All adult patients who underwent LT at two institutions (Vall d’Hebron and Bellvitge University Hospitals, Barcelona, Spain) were included in this prospective cohort study from January 2015 to December 2016. Norfloxacin prophylaxis was considered if the recipient received it during the three months before transplantation. Infections were defined by the isolation of any bacterial microorganism with clinical signs of infection. Patients were stratified into 2 groups based on the presence or absence of MDR infection as defined by Magiorakos AP et al. Student t and chi-square tests and multivariate regression analysis were used to compare the 2 groups.

Results: We included 157 patients. 54 (34.6%) LT recipients were on norfloxacin before LT. The norfloxacin group had a higher median MELD score (20, IQR 14-24, vs 11, IQR 8-19; p<0.001). There were 17 infections due to MDR bacteria, mainly urinary tract infection (9/17, 52.9%). The most isolated MDR microorganism was ESBL Klebsiella pneumoniae (8/17, 47.1%). MDR infection was more frequent in the norfloxacin group (12/54, 22.2% vs 5/97, 4.9%, p=0.002). In the univariate analysis, MELD score (23 vs 13, p=0.001), administration of antibiotics other than norfloxacin prophylaxis (82.4% vs 31.4%, p<0.001) and renal replacement therapy (29.4% vs 5.7%, p=0.004) and ICU admission before LT (35.3% vs 8.6%, p=0.004) and norfloxacin prophylaxis (70.6% vs 30.2%, p=0.002) were associated with MDR infection. In the multivariate analysis, only the use of norfloxacin (OR 3.25; CI 1.02-11.63) and the administration of antibiotics within 3 months prior to LT (OR 5.54; CI 1.53-26.51) showed relationship with the appearance of MDR infection.

Conclusions: The use of norfloxacin as prophylaxis was associated with an increased risk of MDR bacterial infection in the early post-LT period.

Molecular diversity of carbapenem-resistant Enterobacteriaceae (CRE) in Singapore

Jocelyn Teo*1,2, Cheng-Yee Tang1, Sze Min Ong3, Shannon Lee1, Jun Yuan Ho1, Si Hui Tan1, Yiying Cai1, Tze-Peng Lim1,4,5, Thuan Tong Tan1, James Heng Chiak Sim1, Rick Tiew Hee Ong2, Andrea Kwa1,5,6

1Singapore General Hospital, Singapore, Singapore, 2National University of Singapore and National University Health System, Saw Swee Hock School of Public Health, Singapore, Singapore, 3National University of Singapore, Pharmacy, Singapore, Singapore, 4SingHealth Duke-NUS Pathology ACP, Singapore, Singapore, 5SingHealth Duke-NUS Medicine Academic Clinical Programme, Singapore, Singapore, 6Duke-NUS Medical School, Singapore, Singapore

Background: Active surveillance is a key strategy in our combat against CRE. In addition to classical surveillance based on phenotypic methods, whole genome sequencing (WGS) has allowed greater resolution in deciphering the CRE resistome. We described the molecular epidemiology of CRE in a large public healthcare institution across 10 years.

Materials/methods: 824 non-duplicate CRE isolated from inpatients admitted to a large tertiary Singapore hospital between 2008-2018 were sent for paired-end Illumina WGS. Antibiotic susceptibilities were determined using microbroth dilution. Multi-locus sequence typing (MLST) and antibiotic resistance genes analyses were performed. Cultures were classified as infection or colonisation based on the CDC surveillance definitions.

Results: 814 (99%) CRE were MDR. Resistance to last-line agents were detected [resistant rates: fosfomycin – 22%; polymyxin B – 14%; tigecycline – 9%]. Majority of the CRE harboured genes mediating resistance to multiple antibiotic classes. The prevalence of plasmid-mediated resistance genes was high [carbapenemases – 91%, aminoglycoside genes – 89%, fluoroquinolone genes – 73% and ESBLs – 63%]. The predominant carbapenemase genes were \( \text{bla}_{KPC} \) (50%) and \( \text{bla}_{NDM} \) (33%). There was a shift from \( \text{bla}_{NDM} \) to \( \text{bla}_{KPC} \) over the study period. Amongst ESBLs, CTXM-15 was frequently detected (56%). The phenotypic and genotypic susceptibility profiles of colonisers and infection-causing isolates were different. Infection-causing CRE had significantly higher amikacin, aztreonam, levofloxacin, and tigecycline resistance rates and higher proportions of \( \text{bla}_{OXA-48} \) and ESBLs, while \( \text{bla}_{NDM} \) was more common in colonisers. MLST revealed significant genetic diversity in the isolates, with multiple distinct STs and clonal complexes detected. Of note, ST14, the OXA-48 and NDM co-producing clone responsible for several outbreaks, was commonest amongst our \( K. \) pneumoniae (11%). ST131 occurred most frequently in \( E. \) coli (13%). Compared to the \( K. \) pneumoniae and \( E. \) coli, the dominant strain in \( E. \) cloacae (ST93) and \( C. \) freundii (ST22) appeared to be more genetically similar (Figure 1).

Conclusions: CRE in Singapore were MDR and genetically diverse. Resistance to last-line antibiotics has emerged. Genomic analyses suggest that the incidence of CRE was unlikely due to the expansion of single clones nor widespread outbreaks, although there were populations within \( E. \) cloacae and \( C. \) freundii which appeared genetically similar.
**Figure 1:** Distribution of commonly found antibiotic resistance genes in major CRE strains. KP – *K. pneumoniae*; EC – *E. coli*; ENT – *E. cloacae*; CF – *Citrobacter freundii* ST22.

Abstract 5303

**European Centre for Disease Prevention and Control system for cluster detection and interactive exploration of WGS data**

Erik Alm*

1European Center for Disease Prevention and Control, Stockholm, Sweden

**Abstract third-party references:** ECDC

**Background:** ECDC has been collecting WGS data for outbreak investigations since 2015, and has launched continuous WGS surveillance for multi-country outbreak detection and trend monitoring for *Listeria monocytogenes* in 2019. The ECDC strategic framework for the integration of genomic typing into European surveillance and multi-country outbreak investigations foresees that several additional pathogens will be implemented in 2020, including Salmonella, Shiga-toxin producing *E.coli*, *Neisseria meningitidis*, and multidrug-resistant *Mycobacterium tuberculosis*.

**Materials/methods:** ECDC is building a database and web service with very fast WGS data upload, matching and phylogenetic tree building capabilities for large number of isolates. The system does not perform raw data processing steps such as assembly and allele calling; instead, it collects derived results from several sources and optimizes the data for fast exploration. ECDC is also developing a web page with an interactive user interface to allow nominated national public health reference laboratory users in the EU Member States to explore their data in context of other users' data and reference data from public sources such as NCBI and pubMLST. The fast matching uses pre-calculated clusters and a pre-calculated distance matrix based on cgMLST that is stored in a SQL database; the system performs matching and reconstructs the distance matrix using SQL stored procedures, achieving very high performance, enabling real time data exploration.

**Results:** Searching for matches within seven cgMLST allelic differences in a database containing ~20,000 isolates, constructing a phylogenetic tree for ~100 isolate hits and presenting the tree together with epidemiological data to the user in a web browser, as an annotated tree image, an epicurve, a line list and an interactive MicroReact dataset takes less than 2 seconds.

**Conclusions:** ECDC has developed a high-performance interactive WGS data exploration interface for nominated EU Member State users. This system will enable fast and user-friendly contextualization of national WGS data as multi-country outbreak detection and investigations.

**Presenter email address:** erik.alm@ecdc.europa.eu
Performance of the new random access molecular diagnostics analyser Alinity m

Robert Ehret1*, Jens Dhein2, Stefan Breuer1, Martin Obermeier1

1MVZ MedizinischesInfektiologiezentrum Berlin, Berlin, Germany, 2Abbott Molecular, Abbott GmbH & Co. KG, Wiesbaden, Germany

Background: Molecular diagnostics is an essential part of diagnosis and treatment monitoring in infectious disease. Short turn-around-times are a requirement for rapid initiation of treatment and fast identification of treatment failures. New molecular diagnostic platforms allow to perform multiple parallel tests like detection of HIV, Hepatitis C Virus (HCV), Hepatitis B Virus (HBV) without the restriction of batching samples. We compare the assay performance of the new Abbott Alinity m system with the Abbott m2000 and the Hologic Panther platform.

Materials/methods: We tested 1841 clinical samples on the Alinity m system and compared the results to either the m2000 or the Panther. 1089 samples were tested for HIV viral load, 307 for HBV viral load and 445 for HCV viral load. Regression and Bland-Altman analysis was performed for samples with quantitative results. Turn-around-times (TAT) were analysed as time difference between sample arrival in the laboratory and availability of results in the laboratory information system with the same samples tested in parallel.

Results: 198 samples showed quantitative results for HIV (HBV: 151, HCV: 225). Comparison between Alinity m and m2000 showed high coefficients of correlation (HIV: R²=0.96, HCV: R²=0.96, HBV: R²= 0.95) with similar results between Alinity m and Panther (HIV: R²=0.94, HCV: R²=0.99, HBV: R²= 0.90). TAT analysis showed in 1125 samples with one Alinity m 90% of results were available after 11:09 hours compared to 7:12 hours with three m2000. A second set of 1033 samples was compared between one Alinity m and two Panther showing 90% of results were available after 5:46 hours (Alinity m) and 5:13 hours (Panther).

Conclusions: Our analysis shows excellent performance of the Abbott Alinity m system compared to Abbott m2000 and Hologic Panther with high levels of correlation. The analysis of turn-around-time shows a relevant reduction of duration until results can reported to the clinicians compared to the m2000 system, while both random access systems with an optimized pre-analytic workflow showed similar turn-around-times. The Abbott Alinity m allows to run 20 different assays in parallel as compared to 4 on Panther. This increase in automation leads to faster reportable results with less hands-on-time.

**Abstract 5311**

**Title:** Molecular epidemiology and genetic characteristics of New Delhi metallo-β-lactamase among Gram-negative bacteria in a tertiary care hospital of north India

Sanjay Singh*, Avinash Singh, Ashutosh Pathak, Chinmoy Sahu, Kashi Nath Prasad

*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India*

**Background:** Infections caused by Gram-negative bacteria harbouring NDM poses a serious challenge to clinicians and has become a major public health concern. Co-occurrence of multiple resistant genes with blaNDM further complicates the treatment regimen. Presence of blaNDM on transferable plasmids is responsible for its rapid and global dissemination. The present study evaluated the prevalence of blaNDM gene, types of blaNDM variants circulating, genetic location of blaNDM gene and whole genomic analysis of five *K. pneumoniae* harbouring blaNDM gene.

**Materials/methods:** A total of 2000 consecutive isolates of GNB recovered from different clinical specimens from patients admitted to SGPGIMS, Lucknow were included in the study. Susceptibility testing against carbapenems, cephalosporins, aminoglycosides, ciprofloxacin and colistin were performed. PCR was performed for detection of blaNDM and followed by sequencing of selected ninety isolates to determine blaNDM variants. Other resistance genes were also determined in ninety isolates. Conjugation studies and southern hybridisation was performed to determine transfer ability and their genetic location. Whole genome-sequencing of five blaNDM harbouring *K. pneumoniae* was done to understand the genomic dynamics.

**Results:** Out of 2000 isolates 813 (40.6%) isolates were found carbapenem (Imipenem/Meropenem/Doripenem/Ertapenem) resistant. Among 813 carbapenem resistant isolates, 334 (41.8%) were NDM positive by PCR. Sequencing of PCR products revealed the presence of four different variants of blaNDM-1 namely blaNDM-3, blaNDM-5, blaNDM-7, blaNDM-11. Among the ninety blaNDM harbouring GNB other resistance genes were also detected (75% blaIMP, 28.8% blaVIM, 44.4% blaOXA-48, 46.6% blaSHV, 74.4% blaCTX-M, 63.3% ampC, 30% armA, 42.2% Rmt B, and 9% RmtF). Successful conjugation assay proved the transfer ability of blaNDM genes in recipient *E. coli* J53 cells. Southern blot analysis showed that blaNDM genes were located on multiple plasmids of variable sizes. WGS analysis showed presence of genes responsible of resistance to diverse antibiotic groups. Multiple plasmids and virulence factors were also present in the blaNDM producers, and upstream and downstream element of blaNDM gene were also analysed.

**Conclusions:** NDM-positive strains are continuing to spread worldwide despite continuous efforts and remain a critical challenge for public health across the world. Targeted measures are needed to control the spread of blaNDM producers.

**Presenter email address:** singh.sanjay487@gmail.com
Impact of alternative dosing infusions of ceftolozane-tazobactam monotherapy against extremely-resistant *Pseudomonas aeruginosa* sequence type 175 isolates with different susceptibility profile ranging from 2 to 16 mg/L in a hollow-fibre infection model

M. Milagro Montero*1, Sandra Domene Ochoa1, Carla Lopez Causape2, Brian D. Vanscoy3, Sonia Luque1, Luisa Sorlí1, Ariadna Angulo1, Eduardo Padilla1, Nuria Prim4, Virginia Poma4, Alba Rivera2, Nuria Campillo1, Santiago Grau1, Paul G. Ambrose3, Antonio Oliver2, Juan P. Horcajada1

1Hospital del Mar, Barcelona, Spain, 2Hospital Universitario Son Espases, Palma, Spain, 3Institute of Clinical Pharmacodynamics, Schenectady, United States, 4Laboratori de Referencia de Catalunya SA, Prat de Llobregat (El), Spain, 5Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** The optimization of antimicrobial pharmacokinetics/pharmacodynamics (PK/PD) in infections due to XDR *P. aeruginosa* is a constant concern in our environment. As ceftolozane/tazobactam (C/T) is a time-dependent antimicrobial, the use of prolonged infusion could improve the probability of achieving an optimal PK/PD target.

**Objectives:** To compare the alternatives of human-simulated dosing infusions of C/T monotherapy against ST175 *P. aeruginosa* isolates with different C/T MIC values in a hollow-fiber model.

**Materials/methods:** A hollow-fiber model was employed to compare human-simulated exposures of C/T alternatives dosing infusions against three XDR ST175 *P. aeruginosa* clinical isolates with MIC values ranging from 2 to 16 mg/L. C/T dosing regimen simulated was 2/1g every 8h as a 1h (intermittent), 4h (extended) and 24h (continuous) infusion. Bacterial suspension was cultured onto agar supplemented with C/T at 2-fold, 4-fold and 8-fold the baseline MIC to assess the effect of each regimen on at less-susceptible bacterial population. Pharmacokinetic samples were collected and analysed by HPLC.

**Results:** Regarding the susceptibility profiles and resistance mechanisms of the isolates studied, ST175 [10-023] was C/T-susceptible with a MIC of 2mg/L and showed resistance to all β-lactams except C/T caused by OprD inactivation and AmpC hyperproduction. ST175 [09-12] was resistant to C/T with a MIC of 8mg/L and it had a specific mutation in PBP3 associated with increased β-lactam resistance. ST175 [07-016] was C/T-resistant with a MIC of 16mg/L and produced a GES-5. Figure 1 shows the total CFU/mL for the different regimens of C/T in the PK/PD model. The scheme of C/T as a continuous infusion showed greater overall reduction in the bacterial burden against the three isolates, particularly those resistant to C/T. Resistant strains to C/T were not selected with any scheme during the experiment. The simulated drug exposures achieved in this model were considered satisfactory for all regimens.

**Conclusions:** Our study shows that a dosing regimen of 2g/1g of C/T every 8h in a 1h infusion, as currently recommended, did not provide adequate coverage to achieve a good target attainment against *P. aeruginosa* isolates with MICs>2 mg/L. A continuous infusion regimen for C/T should be considered as a useful strategy, especially against C/T-resistant *P. aeruginosa* isolates.
Figure 1. Total CFU/mL using C/T alternatives dosing infusions (1h, 4h and continuous infusion) against three XDR ST175 *P. aeruginosa* clinical isolates, ST175 (10-023), ST175 (09-12) and ST175 (07-016), with MIC values ranging from 2 to 16 mg/L in a hollow-fiber infection model.

**Presenter email address:** 95422@parcdesalutmar.cat
Predicted risk and observed occurrence of *Clostridioides difficile* infection in patients with community-acquired bacterial pneumonia treated with omadacycline or moxifloxacin

Mauricio Rodriguez*1, Kelly Wright1, Bob Noble1

1Paratek Pharmaceuticals, Inc., King of Prussia, United States

**Background:** *Clostridioides difficile* infection (CDI) is the leading cause of healthcare-associated infections and is associated with an average economic burden of $42,000 per case. Use of antibiotics such as fluoroquinolones, cephalosporins, and clindamycin is associated with increased risk of CDI. In this analysis, we compared the risk and number of cases of CDI in patients with community-acquired bacterial pneumonia (CABP) treated with omadacycline or moxifloxacin in the phase 3 OPTIC trial, using the validated Davis scoring index.

**Materials/methods:** Patients were randomized 1:1 to received 100 mg intravenous (IV) omadacycline every 12 hours for two doses then every 24 hours (q24h) or 400 mg IV moxifloxacin q24h, with optional transition to oral after 3 days (omadacycline: 300 mg q24h; moxifloxacin: 400 mg q24h). Total treatment duration, 7–14 days. Risk of CDI (score: 0–10) was calculated per patient using the following factors: number of high-risk antibiotics received (1 point each, maximum 5 points); age (40–55 years: 1 point; >55 years: 2 points); Charlson Comorbidity Index (1 comorbidity: 1 point; >1 comorbidity: 2 points); receipt of proton-pump inhibitors (1 point). Distribution of CDI risk scores was assessed for each treatment group using logistic regression and observed CDI cases were compared using Fisher’s exact test.

**Results:** The omadacycline and moxifloxacin groups included 386 and 388 patients, respectively. Risk of CDI was balanced across the two treatment groups, with overlapping mean and variance distributions. Mean risk score was 4.02 (standard deviation, 1.35) in the omadacycline group and 4.12 (standard deviation, 1.45) in the moxifloxacin group. Risk was also balanced for individual CDI risk scores, with overlapping 95% confidence intervals between treatments (Figure). Observed occurrence of CDI was not balanced between treatment groups: eight cases of CDI were reported in the moxifloxacin group, versus no cases in the omadacycline group (p=0.0037).

**Conclusions:** Despite equal risk across the two treatments, no cases of CDI were seen with omadacycline treatment, whereas eight cases occurred in the moxifloxacin group. The results from this analysis may indicate a lower propensity to induce CDI with omadacycline compared with moxifloxacin treatment.

**Figure:** Predicted risk (95% confidence intervals) of *Clostridioides difficile* infection (CDI) by Davis risk index score for patients with community-acquired bacterial pneumonia, treated with omadacycline or moxifloxacin in the phase 3 OPTIC clinical study

Antibiotic penetration and bioavailability of vancomycin alone and in combination with rifampin in Staphylococcus epidermidis biofilms

Emily O’Neill*1,2; Emily Piehl1,2; Kathryn Daffinee2; Geoffrey Williams1; Kerry Laplante1,2,4

1University of Rhode Island, University of Rhode Island College of Pharmacy, South Kingstown, United States; 2Providence VA Medical Center, Infectious Diseases Research Program, Providence, United States; 3Brown University, Leduc Bioimaging Facility, Providence, United States; 4Brown University, Warren Alpert Medical School of Brown University, Providence, United States

Background: Despite frequent clinical use, a research gap exists regarding the efficacy and interplay of rifampin combination therapy for staphylococcal prosthetic joint infections (P JIs). Questions remain regarding the potential formation of a vancomycin-rifampin molecular complex that may hinder penetration through biofilm matrixes. Our lab’s previous time-kill results utilizing combination vancomycin + rifampin, identified persister cells after 48 hours of antibiotic pressure. Penetration and bioavailability of vancomycin alone, and with rifampin must be determined to elucidate interactions within biofilms.

Materials/methods: S. epidermidis isolate ATCC® 35984, a known biofilm forming bacteria, was grown on polyurethane coupons and stained with FilmTracer™ Sypro® biofilm matrix stain. Simulated humanized concentrations of BODIPY-vancomycin (BODIPY-van) [25 µg/mL] ± rifampin [1.4 µg/mL] were added to biofilm samples and observed over 60 minutes with confocal fluorescence microscopy. Drug diffusion rate was quantified as mean fluorescence intensity (FI) over time with color histograms. Separately, fluorescence recovery after photobleaching (FRAP) was performed at three depths within the biofilm to determine antibiotic bioavailability.

Results: Mean fluorescence intensity increased over 60 minutes in biofilm treated with BODIPY-van but decreased after 30 minutes in biofilm treated with BODIPY-van + rifampin [max FI: 16.25, 13.14 respectively] (figure 1). Generation of a FRAP curve revealed partial fluorescence recovery for BODIPY-van + rifampin at three depths within the biofilm; lower layer: 24%, middle layer: 32%, upper layer: 36%.

Conclusions: Antibiotic diffusion and bioavailability were reduced for BODIPY-van ± rifampin in S. epidermidis biofilms. The addition of rifampin did not improve vancomycin penetration. These data may explain the presence of persister cells identified in time-kill studies with vancomycin + rifampin, that were not observed with vancomycin alone. Further investigation into the molecular interactions with rifampin and other antibiotics, as well as the role of rifampin for biofilm associated P JIs is warranted.

Fig 1: Orthogonal images of S. epidermidis ATCC® 35984 biofilm treated with FilmTracer™ Sypro® biofilm matrix stain (red) at T1min and T60min after antibiotic administration. BODIPY-vancomycin (BODIPY-van) diffusion was incomplete after 60 min and did not reach the lowest layers of the biofilm as confirmed with color histogram. A) Biofilm treated with 25µg/mL BODIPY-van (green) + 1.4 µg/mL rifampin (rif). B) Biofilm treated with 25µg/mL BODIPY-van (green) alone.

Usefulness of qPCR for the assessment of vectorial competence of wild caught sand flies species: preliminary results

Latifa Remadi*1, Najia Chargui1, Maribel Jiménez2, Ricardo Molina2, Najoua Haouas1, Estela González2, Hamouda Babba1

1University of Monastir, Faculty of Pharmacy, Laboratory of Medical and Molecular Parasitology-Mycology LP3M (code LR12ES08), Department of Clinical Biology B, Tunisia, Monastir, Tunisia, 2Carlos III Health Institute, Laboratory of Medical Entomology, National Center for Microbiology, Majadahonda, Spain

Background: Leishmaniases are vector-borne diseases caused by a protozoan parasite of Leishmania (L.) genus and transmitted to humans by the bite of infected female phlebotomine sand flies. In Tunisia, south Mediterranean basin, three pathogenic taxa were described: L. infantum, L. killicki and L. major. The parasite detection in infected sand flies is based especially on the molecular detection using conventional PCR. The aim of this study is to demonstrate the usefulness of qPCR for the assessment of vectorial competence of infected sand flies.

Materials/methods: Sand flies were collected using CDC traps, individual specimens were dissected the head and posterior third segments of the abdomen were served for morphological identification. The abdomen was used for DNA extraction and molecular analysis. Firstly parasite was detected using conventional PCR, then parasite loads were quantified using a qPCR of the kinetoplast minicircle primers JW11 [5'-CCTATTTTACACCAACCCCCAGT-3'] and JW12 [5'-GGGTAGGGGCGTTCTGCGAAA-3']. Parasite typing was performed with nested PCR of the ribosomal internal transcribed spacer 1.

Results: In total 1,029 females were screened for the presence of Leishmania DNA, giving a positive rate of 8.26%. The parasite load was quantified using qPCR in 17 infected sand flies. Among them, seven were engorged and ten were unfed. The highest parasite load was observed in unfed Phlebotomus (Ph.) perfiliewi infected with L. infantum [10,000 parasites] and the lowest one was observed with Ph. perfiliewi infected by L. infantum with 19.9 promastigotes/ reaction. The mean parasite burden in unfed sand flies was 1,174 promastigotes/ reaction, while in engorged females was 90 promastigotes/ reaction.

Conclusions: Our preliminary findings, showed that the high parasite loads are correlated with a persistent feeding pattern and lead to an increase in Leishmania transmission.

Real time PCR results

Antimicrobial activity of plazomicin and old aminoglycosides against clinical isolates of Enterobacterales collected worldwide in 2018

Helio S. Sader*¹; Jennifer Streit¹; Leonard Duncan¹; Jaideep Gogtay²; Cecilia Carvalhaes¹; Mariana Castanheira¹

¹JMI Laboratories, North Liberty, United States; ²Cipla Ltd, Mumbai, India

Abstract third-party references: This study was performed by JMI Laboratories and supported by Cipla Ltd., which included funding for services related to preparing this abstract.

Background: Plazomicin is a new-generation aminoglycoside developed to overcome common aminoglycoside-resistance mechanisms and was approved by the United States Food and Drug Administration (US FDA) to treat complicated urinary tract infection (cUTI), including pyelonephritis. We evaluated the activity of plazomicin and comparator agents against Enterobacterales isolates collected worldwide in 2018.

Materials/methods: A total of 5,519 Enterobacterales isolates were consecutively collected from 92 medical centres located in Europe [38 centres in 18 countries], US [31 centres], Asia-Pacific region [APAC; 13 centres in 7 countries] and Latin America (LATAM; 10 centres in 6 countries), and tested for susceptibility by reference broth microdilution methods in a central monitoring laboratory (JMI Laboratories). MIC results for plazomicin and comparators were interpreted as per US FDA and EUCAST criteria, respectively. Isolates were mainly from cUTI (46.3%) bloodstream infections (BSI; 22.5%), and pneumonia (17.8%).

Results: Plazomicin (MIC₅₀/₉₀, 0.5/2 mg/L) was 4-fold more active than amikacin (MIC₅₀/₉₀, 2/4 mg/L), based on MIC₅₀ values. Plazomicin inhibited 95.0% of isolates at the US-FDA susceptible (S) breakpoint of ≤2 mg/L, whereas amikacin inhibited 95.6% of isolates at the current EUCAST susceptible breakpoint of ≤8 mg/L. Plazomicin activity was consistent across the geographic regions with susceptibility rates ranging from 92.9% in Europe to 96.5% in APAC (table). Moreover, plazomicin was 8- to 64-fold more active than amikacin against ESBL-phenotype, carbapenem-resistant (CRE), multidrug-resistant (MDR), and extensively-drug resistant (XDR) isolates, and retained activity against 83.4% of gentamicin-resistant isolates. CRE rates were highest in LATAM (6.5%) and Europe (6.3%), and lowest in the US (0.7%). The Enterobacterales species most susceptible to plazomicin were E. coli, E. cloacae, K. aerogenes, K. oxytoca, S. marcescens, C. freundii and C. koseri, with MIC₉₀ values of 0.5–1 mg/L and susceptibility of 98.3–100.0%. Plazomicin was also highly active against K. pneumoniae (n=1,819; MIC₉₀, 0.25/0.5 mg/L), with susceptibility ranging from 89.8% in Europe to 99.7% in the US (95.2% overall). Plazomicin activity was very consistent among isolates from cUTI (95.1%S), BSI (95.3%S), and pneumonia (94.3%S).

Conclusions: Plazomicin demonstrated potent activity against contemporary (2018) Enterobacterales isolates collected worldwide, including CRE, MDR, XDR, and gentamicin-resistant isolates.

Abstract third-party references: Dr. Ligia Camera Pierrotti

Background: Solid organ transplant recipients are at high risk for influenza-associated complications, but immune responses to routine standard-dose trivalent inactivated influenza vaccination (SDTIIV) are unsatisfactory, thus prompting further research on double- (DDTIIV) and booster- (BDTIIV) dose trivalent inactivated influenza vaccination regimens.

Materials/methods: We conducted a randomised controlled trial in stable kidney transplant recipients (KTRs) at the University of São Paulo Medical School. We enrolled and randomised 176 KTRs: 59 to SDTIIV, 59 to DDTIIV and 58 to BDTIIV. Fifteen health-care workers were enrolled as a standard-dose controls. Blood was drawn on D0 and D21 to determine pre- and post-vaccination antibody titres. The BDTIIV group was referred for second vaccination on D21 and returned on D42 for blood drawing. Immune responses were measured by seroconversion, seroprotection and geometric mean ratios. Statistical analyses were done by modified intention to treat (mITT) and per protocol (PP). Baseline characteristics, seroconversion and seroprotection rates were compared using Chi-square test. Continuous non-normal variables and geometric mean ratios were compared using Kruskal-Wallis. Age was analysed by analysis of variance. Multivariate analyses were done adjusting for vaccine dose and age.

Results: BDTIIV induced better immune responses in both mITT and PP analyses. In the PP analysis, seroconversion rates (A/H1N1 – 37.5% vs 9.1%, p=0.024; A/H3N2 – 43.8% vs 18.2%, p=0.052; Influenza B – 31.3% vs 25.0%, p=0.758) and geometric mean ratios (A/H1N1 – 2.4 vs 1.3, p=0.013; A/H3N2 – 3.1 vs 1.7, p=0.132; Influenza B – 2.4 vs 2.0, p=0.252) were higher after BDTIIV than SDTIIV, respectively. Additionally BDTIIV induced better seroprotection rates, with statistical significance for A/H3N2 (96.9% vs 70.5%, p=0.002), and was independently associated with seroconversion to A/H3N2 (PR=2.99, 95%CI=1.42-6.26, p=0.003). DDTIIV induced better responses than SDTIIV, albeit without statistical significance.

Conclusions: BDTIIV was superior to DDTIIV regimen. In our view, both regimens require head-to-head multicentre comparisons of their efficacy, while SDTIIV should be unutilized in immunosuppressed individuals due to lower immunogenicity.

Graph 1. Comparison of seroconversion rates per vaccine antigen by vaccination group (per protocol analysis)

Legend: BDTIIV – booster-dose trivalent inactivated influenza vaccination; DDTIIV – double-dose trivalent inactivated influenza vaccination; SDTIIV – standard-dose trivalent inactivated influenza vaccination; HC – healthy control who received SDTIIV

Abstract 5328

**Microbial epidemiology of acute graft pyelonephritis**

Pauline Martinet¹, Scheherazade Rezig*, Luca Lanfranco², Didier Tandé³, Yannick Le Meur², Severine Ansart¹

¹Brest Teaching Hospital, Infectious Disease Unit, Brest, France, ²Brest Teaching Hospital, Department of Nephrology, Hemodialysis and Kidney Transplantation, Brest, France, ³Brest Teaching Hospital, Department of Microbiology, Brest, France

**Background:** Acute graft pyelonephritis (AGPN) is a very common infection in renal transplantation. However, there is no specific practice guideline for the management of urinary tract infections (UTI) in kidney transplant recipients. Third generation cephalosporin or fluoroquinolone are recommended for empirical antibiotic therapy of community-acquired pyelonephritis; fourth-generation cephalosporin or piperacilline-tazobactam are recommended for the empirical antibiotic therapy of healthcare associated UTI. We suspect a higher rate of resistance to those drugs in kidney transplant recipient than in general population.

The aim of this study was to described microbial epidemiology of AGPN in our center and thus assesses the applicability of French guidelines for management of UTI in a kidney-transplant recipient.

**Materials/methods:** We conducted a single-center retrospective observational study on a population of kidney transplant recipients who were diagnosed with AGPN between January 2017 and December 2018. We defined AGPN as the association of fever and/or urinary tract symptoms and significant leucocyturia and bacteriuria (according to French guidelines).

**Results:** We retrospectively identified 106 AGPN in which 110 bacteria were involved. The rates of community-acquired and healthcare associated AGPN were respectively 54.7% (n=58/106) and 45.3% (n=48/106). Enterobacteriaceae were the most frequent pathogen encountered representing 87.2% of bacteria involved (n=96/110). Among these, 27.1% (n=26/96) were resistant to third-generation cephalosporins. This resistance was due to extended spectrum beta lactamase (ESBL) in 84.6% (n=22/26) and cephalosporinase in 15.3% (n=4/26). Concerning fluoroquinolones, 42.7% (n=41/96) of Enterobacteriaceae were resistant to this class of antibiotic.

**Conclusions:** Due to high rates of resistance to third-generation cephalosporins and quinolones, French practice guidelines for empirical antibiotic therapy of acute pyelonephritis do not seem applicable to a kidney-transplanted population. We need to repeat this study on a larger and prospective scale. If these results are confirmed, we propose the systematic addition of aminoglycosides to third-generation cephalosporins for the empirical antibiotic therapy of AGPN.

Piglets as a potential reservoir of atypical enteropathogenic *Escherichia coli* (aEPEC) with serotypes of human enterohaemorrhagic *Escherichia coli* (EHEC), including the O80:H2-A-ST301 (CH27-54) eae-ξ clone

Isidro García-Meníño*, Azucena Mora Gutiérrez1, Miguel Blanco1, Jesús Eulogio Blanco Alvarez1, Vanesa García Menéndez1, Saskia C. Flament-Simon1, Dafne Díaz-Jiménez1, Pilar Alonso2, Jorge Blanco1

1University of Santiago de Compostela, Laboratorio de Referencia de *E. coli* (LREC), Dpto. de Microbiologia e Parasitoloxía, Santiago de Compostela, Spain, 2Hospital Lucus Augusti (HULA), Unidad de Microbiologia Clínica, Lugo, Spain

**Background:** For aEPEC, both animals and humans can be reservoirs and are known as pathogenic for children and pigs. The concept of interconversion between EHEC and aEPEC have been previously suggested. Thus, the aim of the present study was to define porcine aEPEC clones and its comparison with clinical human aEPEC.

**Materials/methods:** Ninety-two porcine aEPEC isolates were characterized with regard to their serotypes, phylogroups, clonal types (CH), sequence types (ST), verotoxins, intimin types, and pulsed field gel electrophoresis (PFGE). In addition, porcine aEPEC were compared with aEPEC isolated from human patients with diarrhea.

**Conclusions:** Our results show that piglets with diarrhea represent a significant reservoir of aEPEC potentially pathogenic for humans. Importantly, the recently described O80:H2-A-ST301 (CH27-54) eae-ξ clone was detected in nine (9.8%) isolates. This highly virulent clone has been associated with hemolytic uremic syndrome and hemorrhagic colitis.

**Abstract 5335**

**Pathogenic determinants of the Mycobacterium kansasii complex: an unsuspected role for distributive conjugal transfer**

Florian Tagini*, Trestan Pillonel†, Claire Bertelli‡, Katia Jaton*, Gilbert Greub‡

*Lausanne University Hospital, Institute of Microbiology, Lausanne, Switzerland

**Background:** The former *Mycobacterium kansasii* species, comprising six major subtypes, was recently reclassified into six species-level lineages. Together with *Mycobacterium gastri*, they form the *M. kansasii* complex. *M. kansasii* (subtype 1) is the most frequent and most pathogenic species of the complex. *M. persicum* (subtype 2) is classically associated with diseases in immunosuppressed patients. The other species are mostly found as lung colonizers and only very rarely reported to cause disease. To unravel the genetic determinants contributing to their different pathogenicity, we performed a comparative genomics study of the *M. kansasii* complex.

**Materials/methods:** Genomes of 51 isolates collected from patients with and without disease were sequenced and compared with 24 additional publicly available genomes. The pathogenicity of each isolate was determined based on clinical records or public metadata. Comparisons of virulence factor homologs were performed using Orthofinder-defined groups loaded in a MySQL database. Genome-wide association study (GWAS) was done using matrices of presence/absence of single-copy homolog and of core genome SNPs. Distributive conjugal transfers (DCTs) were detected using sequence-identity approaches.

**Results:** *M. persicum* (subtype 2), *Candidatus M. fractum* (subtype 4), *M. innocens* (subtype 5) and *M. gastri* isolates lacked the ESX-1-associated EspACD locus that is thought to play a crucial role in the pathogenicity of *M. tuberculosis* and other non-tuberculous mycobacteria. Furthermore, *M. kansasii* was the only species exhibiting a 25Kb-large genomic island encoding for 17 type-VII secretion system-associated proteins. The GWAS revealed that two genes encoding a hemerythin-like and a nitroreductase-like proteins were significantly associated with pathogenicity. These genes may be involved in resistance to reactive oxygen and nitrogen species, an essential mechanism for intracellular survival of bacteria. Three non-pathogenic *M. kansasii* isolates lacked these genes likely due to two distinct DCTs between *M. attenuatum* (subtype 6) and *M. kansasii*, and one DCT between *M. persicum* and *M. kansasii*.

**Conclusions:** Large differences in virulence gene content were observed in the *M. kansasii* complex, all of which could contribute to the observed differences in pathogenicity. In addition, this study links for the first time DCT – a recently-described mycobacterial type of horizontal gene transfer – to bacterial virulence modulation.

Abstract 5338

Carbapenemase-producing Enterobacterales among urinary isolates from community in Belgrade, Serbia

Snežana Brkić*, Drina Topalov†, Dragana Božić‡, Nena Stojanović§, Ivana Cirkovic∥

1Institute for Laboratory Diagnostics “Konzilijum”, Belgrade, Serbia, 2University of Belgrade, Faculty of Pharmacy, Department of Microbiology and Immunology, Belgrad, Serbia, 3City Institute of Public Health of Belgrade, Belgrade, Serbia, 4University of Belgrade, Faculty of Medicine, Institute of Microbiology and Immunology, Belgrade, Serbia

Background: Urinary tract infections represent the main cause of antibiotics prescription and consumption in primary healthcare settings. Despite that, the data about acquired resistance among community bacterial isolates remains largely unknown. The aim of this study was to determine the prevalence and the types of carbapenemases among urinary isolates of Enterobacterales from community patients in Belgrade, Serbia.

Materials/methods: Study was conducted in 2016 and 2017 in two community-serving microbiology laboratories, which receive samples from primary care settings for the local population of around 1.6 million. Urinary tract isolates were identified by MALDI-TOF MS (VITEK MS, bioMerieux). Enterobacterales isolates were screened for carbapenemase production with meropenem 10 µg disk (BioRad, France), according to the EUCAST recommendations. For screening-positive isolates, multiplex PCR for bla_KPC, bla_NDM, bla_IMP, bla_OXA-48-like was performed. Susceptibility to colistin was determined with the broth microdilution method. The detection of mcr-1 to mcr-5 genes was done for the colistin resistant isolates.

Results: In total, 39117 Enterobacterales urinary isolates were screened for carbapenemase production. Screening was positive for 159 (0.41%) isolates, and the carbapenemase genes were confirmed in 131/159 (82.4%) isolates. The most common species was Klebsiella pneumoniae (105/131, 80.1%), with the most frequent carbapenemase genes bla_OXA-48-like (81.9%), bla_KPC (8.6%) and bla_NDM (7.6%), respectively. All 17 Enterobacter cloaceae/asburiae isolates were carbapenemase producers, with 70.6% harboring bla_NDM and bla_OXA-48-like genes. Four Providencia spp., 3 Escherichia coli and 2 Proteus mirabilis isolates were bla_NDM positive. Two isolates (Providencia stuartii and P. mirabilis) were positive for the bla_VIM carbapenemase gene. bla_OXA-48-like was not found. Resistance to colistin was detected in 17/131 (13%) strains of K. pneumoniae exclusively, but no mcr-1-5 genes were confirmed.

Conclusions: Previous researches in Serbia, all based in hospital settings, found bla_NDM as the most common carbapenemase in K. pneumoniae and E. coli. In our study, bla_OXA-48-like was the most frequent one among community Enterobacterales isolates. This may suggests the shift in carbapenemases types in Enterobacterales, as community patients could be reservoirs of carbapenemase-producing bacteria with the potential to spread to hospital settings.

Co-production of KPC and SPM carbapenemases by *Pseudomonas aeruginosa* in same hospital in northern Brazil

Ana Judith Quaresma*, Lívia Maria Guerra Dutra¹, Michelle Simone Ferreira Ribeiro¹, Rebeca Nazaré¹, Danielle Brasiliense¹

¹Instituto Evandro Chagas, Ministério da Saúde do Brasil, Ananindeua, Brazil

Abstract third-party references: Instituto Evandro Chagas/SVS/MS

**Background:** *Pseudomonas aeruginosa* is one of the most common opportunistic pathogens associated with nosocomial respiratory infections. Its adaptation to the hospital environment coupled with the high level of intrinsic resistance and the ability to acquire additional resistance mechanisms make antimicrobial therapy challenging in hospitals around the world. Among these mechanisms, carbapenemases are particularly important because of the ease of intra and interspecies dissemination.

**Materials/methods:** The isolates are part of the collection of cultures of the Section of Bacteriology and Mycology of the Evandro Chagas Institute, received from hospitals in the northern region of Brazil, from January 2018 to May 2019, for epidemiological surveillance of bacterial isolates resistant to carbapenens. The detection of genes encoding carbapenemases was performed by PCR, where the presence of the genes blaKPC, blaNDM, blaOXA-48-LIKE, blaIMP, blaVIM and blaSPM were investigated.

**Results:** Of the total of 84 *P. aeruginosa* isolates, 10 (12%) were producers of SPM type carbapenemases. Among these, in five isolates of the same hospital, obtained from tracheal secretion and urine, the simultaneous presence of the blaKPC and blaSPM genes was observed. It is worth noting that the phenotypic test using EDTA and phenylboronic acid was negative in these isolates.

**Conclusions:** We report the presence of two different carbapenemases (KPC and SPM) in five clinical isolates of *P. aeruginosa*. The production of carbapenemases in *P. aeruginosa* is still relatively rare in the Northern region. However, these findings demonstrate the ability of this microorganism to act as reservoir and dispersion vector of resistance determinants. This coproduction points to a possible change in the genetic context that can confer a high level of resistance to carbapenems, and it is necessary to evaluate their impact on patients’ morbidity and mortality. We also emphasize the importance of monitoring these pathogens as a strategy to minimize the circulation and dissemination of these resistance mechanisms in hospitals.

Abstract 5340

TLR4-independent effects of LPS identified using longitudinal serum proteomics
Erin Harberts*, Tao Liang, Sung Hwan Yoon, Belita Opene, David Goodlett, Robert Ernst

1University of Maryland - Baltimore, Baltimore, United States

Background: Sepsis remains one of the most lethal and costly conditions treated in hospitals worldwide, with about 50% of reported cases caused by Gram-negative bacterial infections. Gram-negative septic shock is largely induced by signaling of LPS, a main component of the outer bacterial membrane, through the innate immune receptor toll-like receptor 4 (TLR4). We used label-free quantitative [LFQ] proteomics to analyze changes in serum proteomes of mice that were either susceptible or resistant to LPS induced endotoxemia.

Materials/methods: WT and TLR4-/- C57BL/6 mice were injected with a lethal dose of Escherichia coli LPS (30 mg/kg) or PBS and serum collected every 6 hours post injection (n=3 per group). Tryptic digestion of 2 µL serum from each sample was subjected to LC-MS/MS followed by MaxQuant analysis. Data were analyzed longitudinally with global ANOVA and Ingenuity Pathway Analysis [IPA].

Results: PBS treated WT mice and LPS treated TLR4-/- mice showed no clinical signs of septicemia, while WT LPS treated mice showed symptomatic and molecular phenotype over 24 hours. Longitudinal serum proteome analysis [baseline = 0h] identified 182 out of 324 proteins in LPS injected WT mice were significantly changed across four time points (0, 6, 12 and 18h). From these 182 proteins, known sepsis biomarkers were validated by ELISA and showed similar trends to the LC-MS/MS data. No significant changes were identified in the two control groups. A global analysis found 69 significantly changed proteins unique to the WT injected LPS group, and 51 significantly changed proteins common among the WT and TLR4-/- LPS injected groups.

Conclusions: These studies validate proteomics and data analyses approaches for use in longitudinal studies and support the use of longitudinal comparisons for complex animal models of disease rather than traditional pair-wise comparisons. The global analysis of WT and TLR4-/- mice identified pathways activated independent of TLR4 which represent possible compensatory mechanisms that allow for control of Gram-negative bacterial infection regardless of host immune status.

Abstract 5341

**Population structure dynamics of *Escherichia coli* ST131 over time**

Gisele Peirano*, Tarah Lynch, Rebekah Devinney, Thomas Finn, Yasufumi Matsumura, Johann Pitout

1University of Calgary, Calgary, Canada, 2Kyoto University Graduate School of Medicine, Kyoto, Japan

**Background:** *Escherichia coli* ST131 is one of the most successful global antimicrobial drug resistant (AMR) clones among human isolates. Limited information is available regarding the population structure dynamics of ST131 over extended time periods. A study was designed to characterize ST131 responsible for blood stream infections over an 11 year period in a large well-defined Canadian geographical region.

**Materials/methods:** All *E. coli* from blood (n=1784) obtained in the Calgary region during 2006, 2012 and 2016 were screened with a ST131 PCR. Isolates positive for ST131 (n=344) underwent Illumina whole genome sequencing.

**Results:** Overall 19% of *E. coli* were PCR positive for ST131; the prevalence of ST131 increased from 11% in 2006 to 24% in 2012 and 21% in 2016. The majority of ST131 belonged to clade C (81%) followed by clades A (10%) and B (9%). Clade C (n=278) belonged to subclades C1-nonM27 (44%), C1-M27 (6%) and C2 (50%). ST131 clades were associated with different *fimH* alleles (e.g. A with *fimH*41, C with *fimH*30), IncF replicons (e.g. A with IncFII; B with IncFIB; C with IncFIA) and AMR determinants (e.g. A with *aph(3")*-Ib; B with *aadA*2; C1-nonM27 with *aph(3")*-Ia; C1-M27 with *bla* _CTX-M-27_ and *aph(3")*-Ib; C2 with *bla* _CTX-M-15_ and *aac(6")*-Ib-cr). The frequencies of clades A, C1-M27 and C2 increased while clades B and C1-nonM27 decreased over time. C1-nonM27 was the dominant subclade in 2006 while C2 with *bla* _CTX-M-15_ and C1-M27 with *bla* _CTX-M-27_ were responsible for the increase of ST131 among *E. coli* during 2012 and 2016.

**Conclusions:** This study demonstrates that the population structure of ST131 in a large Canadian geographic health care region is dynamic with the continuous interplay and emergence of different clades and subclades with various AMR determinates over time.

The diagnostic impact of adding a molecular-based algorithm to routine mycobacterial testing for non-respiratory samples at a reference Saudi Arabian laboratory

Abdulwahab Binjomah*1, Amani Alnimr2, Suzan Zareah1, Khalid Alasmari1, Shafi Alharbi1, Abdulaziz Aljubran1, Eman Alshammari1, Arwa Alharbi1, Kamel Aldosari1

1Regional Lab in Riyadh and Blood Bank, Ministry of Health, Riyadh, Saudi Arabia, 2Imam Abdulrahman Bin Faisal University, Ministry of Education, Dammam, Saudi Arabia

Abstract third-party references: Mycobacteriology Reference Laboratory in Riyadh, Diagnostic Microbiology, Riyadh Regional Laboratory & Blood Bank

Background: Extrapulmonary tuberculosis poses microbiological challenges due to the paucibacillary nature of the disease leading to low diagnostic yields. Here we sought to evaluate the impact of adding a rapid molecular diagnostic tool to the routine testing algorithm for extrapulmonary mycobacterial infections at a reference laboratory setting in a country with an intermediate prevalence of the disease.

Materials/methods: This cross-sectional study was conducted at the Mycobacteriology Reference Laboratory in Riyadh, Saudi Arabia. All non-respiratory specimens routinely received between 2012-2019 from patients suspected of having tuberculosis were included. Specimens were subjected to smear microscopy, liquid MGIT culture and susceptibility testing, direct Xpert MTB/RIF (Xpert) assay. The diagnostic accuracy of Xpert was calculated along with the incremental yield compared to microscopy.

Results: Among 2985 non-respiratory specimens investigated, 255 turned to be culture positive (38 tissue biopsies, 90 pus from lymph nodes, 15 gastric aspirate, 9 urine, 77 pleural, 11 cerebrospinal and 15 other body fluids). The pooled sensitivity and specificity of Xpert were 69.4% (95% CI 57.9-88.9%) and 100% (95% CI 98-100%) respectively when compared to the culture. The highest sensitivity was documented for pus (94%; 95% CI 86.5-97.3%) and urine specimens (88.9%; 95% CI 75-93.4%) with an incremental yield of 78.9 and 88.9% compared to microscopy. Moderate sensitivity for cerebrospinal fluid (81.9%; 95% CI 58.7-89.2%) pleural fluid (68.8%; 95% CI 47-77.9%) and tissues (57.9%; 95% CI 36.8-65.4%), with an incremental yield of 63.6, 41.1 and 47.4%, while the sensitivity was lowest for other body fluids (40%; 95% CI 0-57%). The rate of isoniazid monoresistance, multidrug resistance and polydrug resistance were 11, 5.8 and 3.2% respectively. Xpert detected rifampicin resistance in all but one patient and gave 1 false positive result showing an overall agreement of 77.7% (95% CI 68.5-83.7%) with phenotypic susceptibility testing.

Conclusions: Xpert can be an initial diagnostic tool for testing suspected cases of renal TB and tuberculous lymphadenitis. The added value to diagnose other forms of TB needs to consider the inferior sensitivity. Future evaluation of molecular assays needs to compare them to a composite reference standard considering the clinical and laboratory limitations.
A prediction model for identification of patients at high risk for Staphylococcus aureus intensive care unit pneumonia and implications for trial design

Claudia Recanatini1*, Fleur Paling1, Derek Hazard2, Jafri S Hasan3, Omar Ali3, Frangiscos Sifakis4, Herman Goossens5, Surbhi Malhotra-Kumar5, Willek J.B. Van Wamel6, Martin Wolkewitz2, Marc J.M. Bonten1,7, Jan A. J. W. Kluytmans1,8

Abstract third-party references: This research project receives support from the Innovative Medicines Initiative Joint Undertaking under grant agreement n° 115523, 115620, 115737 resources of which are composed of financial contribution from the European Union Seventh Framework Programme (FP7/2007-2013) and EFPIA companies in kind contribution.

Background: Staphylococcus aureus (SA) is an important cause of pneumonia acquired in the intensive care unit (ICU). Identifying patients at high risk of developing SA ICU-acquired pneumonia (SAIP) is essential for targeting preventive strategies and enhancing the efficiency of clinical trials. The aim of this study was to derive a prognostic prediction model to quantify the risk of acquiring SAIP by using a composite score of independent risk factors and assess its implications to trial design.

Materials/methods: We used data from ASPIRE-ICU, a prospective observational cohort study conducted at 30 European ICUs enrolling SA colonized and non-colonized subjects in a 1:1 ratio. SAIP development was assessed daily and was defined as pneumonia occurring >48 hours after ICU admission with SA was cultured from the lower respiratory tract or blood. A logistic regression model for SAIP was fitted using information available at ICU admission. Pre-defined predictors were selected based on the Akaike’s Information Criterion. Predictive performance, discrimination and calibration of the final model were assessed. Internal validation was performed using bootstrapping.

Results: Of 1,929 patients analyzed, 131 (6.8%) developed SAIP. The final logistic regression model included the following predictors: SA colonization status [OR: 3.20, 95%CI: 2.15-4.91, p<0.01], neurotrauma, defined as patients admitted with trauma and a Glasgow Coma Scale <8, [OR: 1.67, 95%CI: 1.02-2.66, p=0.04], and antibiotic use in the two weeks preceding ICU admission [OR:0.55, 95%CI: 0.31-0.90, p=0.03]. The area under the receiver operating characteristic curve was 0.73 (95%CI: 0.67-0.79) and decreased to 0.71 after internal validation. Model calibration was moderate [Brier score 0.063]. The model demonstrated that 9 subjects are needed to identify one SAIP case when using SA colonization at admission and/or neurotrauma (SAIP risk: 10.9%) as inclusion criteria, compared to 19 subjects needed to identify one SAIP when enrolling from the overall ICU population [SAIP risk of 5.3%].

Conclusions: S. aureus colonization status at ICU admission, neurotrauma, and antibiotic use in the two weeks preceding ICU admission performed moderately in predicting the risk of developing S. aureus pneumonia during ICU stay. Colonization status would be the most relevant predictor in terms of trial design and execution efficiency.

**Standardisation and validation of the PCR technique for detection of ST16-KL51 serotype among Klebsiella pneumoniae isolates**

Juliana Paulino1, Diego Andrey2, willames Brasilheiro Martins1, Nilton Lincopan1, Ana Gales*1

1Federal University of São Paulo, São Paulo, Brazil, 2Geneva University Hospitals and Medical School HUG, Geneva, Switzerland, 3University of São Paulo, São Paulo, Brazil

**Background:** Recently, bloodstream infections caused by KPC-2-producing KPN Sequence type (ST) 16 were associated with high mortality rates. Interestingly, all ST16 KPN belonged to capsular serotype KL51. MLST have been considered an important methodology to characterize bacterial isolates because sequence data are unambiguous, and the allelic profiles of isolates can easily be compared to those in a large central database. However, it requires 7 PCR and 14 DNA sequencing reactions. We aim to develop a single PCR reaction to easily identify ST16-KL51 in KPN clinical isolates.

**Materials/methods:** For selection of PCR targets, genomes of KP-ST16 available on GenBank, were aligned by Genious Prime to identify a single locus just present in this background. Thus, an inner portion of hpKL51 capsule was selected. The following primers were used for PCR assay: 1. hpKL51internalF: 5’-AGCATCTCTGGCCAACGATAA-3’, 2. hpKL51internalR: 5’-CTGTCTTACCTGGCGTACCT-3’ (product size, 500pb). The study included 132 KPN isolates either characterized by MLST or WGS. The PCR reaction contained: 5ul de Top Taq® Master Mix Kit, Qiagen, 3ul of water, 1ul of loading and 0.25 ul of the primers (0.2 uM/L). To evaluate PCR accuracy, data were submitted to the MedCalcv19.1 statistical test to construct the ROC curve. The higher the AUC value (over 0.9), closer the curve approaches upper left corner, indicated higher sensitivity and lower proportion of false positives.

**Results:** Genomic analysis revealed that, in our collection only the ST-16-KPN (all associated to human infections) and ST231 (animal infections) have the K51 capsule, and consequently the pkL51 gene. PCR was highly discriminatory being positive with all KP-ST16 isolates (n=21/21) and KP-ST231 (n=1/1). The other 110 isolates that presented negative PCR belonged to other STs as following: ST11 (n=34), ST258 (n=44), ST437 (n=14), ST15 (n=8), ST101 (n=5), ST307 (n=2), ST29 (n=1), ST20 (n=1) and non-typed ST (n=1). The ROC curve showed AUC value of 0.995 and p<0.001, presenting 100% of sensitivity and 99.1 of specificity to detect the ST16.

**Conclusions:** This PCR showed excellent discriminatory power to identify ST16-KL51 in KP clinical isolates, since ST231 is not frequent in human specimens and could constitute an alternative option to MLST.

Frequency and impact of differences across Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and Cockcroft-Gault (C/G) estimations of glomerular filtration rate on antimicrobial dosing

Domenick Francis¹, Brian Potoski*²

¹University of Pittsburgh, School of Pharmacy, Pittsburgh, United States, ²University of Pittsburgh, University of Pittsburgh Medical Center, Presbyterian Campus, Pittsburgh, United States

Background: Estimation of glomerular filtration rate (GFR) is the most commonly used patient-specific parameter to determine medication dosing. However, the EMA and FDA recommend different GFR estimation methods, CKD-EPI and C/G, respectively. Further, an electronic medical record (EMR) in the United States may provide both, potentially yielding differences across renal dosing thresholds leading to discordance in dosing selection. We sought to quantify the frequency of these discordant results, and further describe associations which may allow for greater opportunities for education and antimicrobial stewardship interventions.

Materials/methods: A one-month retrospective snapshot of select new intravenous antimicrobial starts were queried using decision support software (TheraDoc). Antimicrobials included were comprised of the greatest frequency of use by institution-specific days of therapy (DOT) along with novel agents including meropenem; ciprofloxacin; piperacillin-tazobactam; cefepime; ceftolozane-tazobactam; ceftazidime-avibactam; and meropenem-vaborbactam. Patient demographics, EMR provided CKD-EPI and C/G calculations, and infectious disease service consults were collected. Patients were excluded from analysis due to renal-replacement therapies, one-time orders, unstable renal function, and missing data. Duplicate patients were excluded unless different antibiotics were represented. Patient comparisons of GFR data across methods were performed and evaluated based on discordance with FDA approved renal dosing threshold recommendations and antimicrobial dosing regimens selected.

Results: Of the 622 patients initially identified, 388 remained after exclusion criteria applied. When evaluating for patient renal dosing threshold categorical discordance by comparing CKD-EPI with C/G lean body mass; C/G ideal body weight; and C/G actual body weight, results were 62 (15.9%), 28 (7.2%); and 43 (11%), respectively. Renal dosing threshold discordance between CKD-EPI and C/G lean body mass lead to dosing selections in 37 (59.7%) and 25 (40.3%) instances, respectively. GFR discordance by renal dosing thresholds were more likely to occur in females (p<0.00001) and older patients (p<0.00001).

Conclusions: The observed differences in dosing selection by GFR method is significant and may yield under- or over-dosing of renally eliminated antimicrobials with clinical outcome implications. Institutions should minimize the number of reported GFR methods in the EMR, and provide recommendations to clinicians regarding an endorsed GFR estimation approach. Antimicrobial stewardship programs are well positioned to incorporate GFR estimation as part of ongoing educational efforts.

Successful introduction of a bundle of measures to reduce surgical site infection by *Staphylococcus aureus* in patients undergoing coronary artery bypass grafting

Ercilia Evangelista De Souza¹, Larissa Gordilho Mutti Carvalho¹, Diego Feriani¹, Aline Santos Ibanes¹, Vera Lucia Barros Barbosa¹, Eliana Vasconcelos¹, Cely Abboud*¹

¹Instituto Dante Pazzanese de Cardiologia, Instituto Dante Pazzanese de Cardiologia, São Paulo, Brazil

**Background:** *Staphylococcus aureus* is the major cause of surgical site infection (SSI) after coronary artery bypass grafting (CABG) worldwide. We observed in our institution that *S. aureus* SSI rate increased in the last year, mainly in patients undergoing CABG.

**Materials/methods:** Quasi-experimental study conducted at a Brazilian public teaching and research hospital, reference in cardiovascular surgery, aiming the reduction of SSI by *S. aureus* in CABG. Intervention measures were carried out from January to October 2019, consisting in (1) bath on the day of surgery with chlorhexidine digluconate 2% wipes; (2) screening for *S. aureus* nasal carriage and use of nasal mupirocin ointment if positive test; (3) change in antimicrobial prophylaxis from vancomycin and ceftriaxone to vancomycin and cefuroxime. The definition of SSI was according to CDC criteria.

**Results:** There were 630 surgeries before and 513 after the intervention starts. In the pre-intervention period (12 months) the CABG SSI rate caused by *S. aureus* was 3.49% and in the intervention period (10 months) the rate was 0.97%, representing a 73% reduction (P = 0.006). We observed a reduction in superficial, deep incisional and organ / space SSI, but only superficial incisional reduction was significant [Table 1]. The positivity of *S. aureus* in nasal swab was 10.35% (47/454) and 90% was methicillin-susceptible. In 59 patients the screening for *S. aureus* carriage was not performed.

**Conclusions:** The implementation of a multifaceted perioperative surgical site infection prevention bundle was associated with a significant reduction in surgical site infection rate by *S. aureus* in patients undergoing CABG.

Abstract 5352

**Feasible approach to reduce antibiotic overuse in preterm neonates**

Jakob Armann*,1, Lars Mense1, Barbara Seipolt1, Mario Rüdiger1, Reinhard Berner1

1Dresden, University Children’s Hospital, Dresden, Germany

**Background:** Empiric antibiotics in early onset sepsis (EOS) in neonates are used to improve outcome. They are generally started based on maternal risk factors and clinical presentation of the neonate shortly after birth. This leads to an overuse of antibiotics with well described adverse effects in this age group. The use of biomarkers to guide the initiation of antibiotics is controversial whereas their use to support treatment discontinuation after sepsis is ruled out is well described.

We use a combination of maternal risk factors, clinical presentation and biomarkers (WBC, I/T ratio, CrP and IL-6) to start empiric antibiotics in newborns. This study aims to evaluate this approach for preterm infants with premature rupture of membranes (PROM) who are at high risk for EOS.

**Materials/methods:** Retrospective chart review and analysis of clinical, epidemiological and microbiological data of all infants < 37 weeks gestation and rupture of membranes at least 1h prior to delivery at our institution between January 2015 and March 2019. Clinical sepsis (CS) was defined as antibiotic treatment of at least five days with sterile blood culture, blood culture positive sepsis (BCxS) as antibiotic treatment of at least five days and growth of any bacteria but coagulase negative staphylococci.

**Results:** 456 infants were identified using these criteria. 120 (26%) received empiric antibiotics whereas 336 (74%) did not. Of those receiving empiric antibiotics 13 (11%) had a BCxS, 46 (38%) a CS and in 61 (51%) sepsis was ruled out and antibiotics were stopped after 48-96h. All infants with BCxS were identified and treated within the first 24h of life using this approach and none of the 336 infants who were not started on empiric antibiotics needed antibiotic therapy within the first 5 days of life. Only 9 premature infants were treated with empiric antibiotics to treat one BCxS. There were no deaths, IVH > grade 1, NEC or BPD observed in the group that did not receive empiric antibiotics.

**Conclusions:** A combination of clinical presentation and biomarkers at birth can safely be used in a high risk population for EOS to reduce the overuse of antibiotics.

**Presenter email address:** jakob.armann@uniklinikum-dresden.de
**Abstract 5353**

**A systematic literature review of the efficacy and tolerability of polymyxins in resistant Gram-negative infections**

Ryan Dillon¹, Ann Colosia², Shahnaz Khan², Catherine Masaquel³, Eilish Mccann*⁴

¹Merck & Co., Inc., Kenilworth, United States, ²RTI Health Solutions, Durham County, United States, ³RTI Health Solutions, Santa Clara, United States

**Background:** The development of antibiotic resistance in Gram-negative bacteria is a serious global problem. Resistance limits the number of antibiotics which can successfully treat bacterial infections; consequently, clinicians are increasingly reintroducing polymyxins into clinical practice despite evidence of toxicity. This review summarizes current published literature reporting the efficacy/tolerability of polymyxins in patients with carbapenem-, multidrug-, or extensively-drug resistant Gram-negative infections.

**Materials/methods:** Eligibility criteria were developed using the PICOS framework. Searches of MEDLINE®, MEDLINE® In-process, Embase®, and Cochrane were conducted in November 2018. Eligible studies reported efficacy and/or tolerability outcomes for patients with resistant infections who were treated with polymyxins. Data were descriptively summarized.

**Results:** 2,219 identified articles; 48 articles representing 46 unique studies met eligibility criteria (four randomized controlled trials [RCTs], 42 observational studies). All RCTs evaluated colistin; of the observational studies: colistin (n=35), polymyxin B (n=4), multiple polymyxins (n=3). Studies were heterogenous with respect to size, causative pathogens, and antibiotic susceptibility definition. One RCT reported infection-related mortality: 26.6% [monotherapy] vs. 21.2% [combination]. Three RCTs reported Day 28-30 all-cause mortality rates of 24%-45%; there were no significant differences by formulation or monotherapy/combination therapy. All-cause mortality reported in 12 observational studies ranged from 11%-83%. Clinical response rate in one RCT: 21% [monotherapy] vs. 27% [combination], 10 observational studies: 20%-87% (median: 53%), one of which showed significantly lower rates with low-dose vs. high-dose colistin; clinical cure rates in one RCT: 67% (aerosolized) vs. 72% [intravenous], 11 observational studies: 18%-82% (median: 55%); microbiological cure in two RCTs: 45%-69%, 15 observational studies: 32%-88% (median: 67%). Nephrotoxicity (per RIFLE criteria) was measured in three RCTs, ranging from 15%-48%; a similar range was seen in three observational studies [7%-51%]. Neurotoxicity was measured in 17 observational studies but was less common, with reported rates of 0%-15%.

**Conclusions:** Published literature demonstrates acceptable response rates but unacceptably high mortality rates. Clinically and economically impactful adverse events such as nephrotoxicity were also observed. Although a large degree of heterogeneity exists in the identified evidence base, available data suggest that polymyxins may be sub-optimal treatments for serious bacterial infections, with a need for alternative treatments with better efficacy and tolerability profiles.

Abstract 5355

**Nocardia Infection over 10 years (2009-2019) in a Greek tertiary university hospital**

Eleni Kalogeropoulou¹, Fanourios Kontos*, Sofia Damianidou², Paraskevas Tsilikis¹, Konstantina Orlandou¹, Barbara Basilopoulou¹, Paraskevi Varda¹, Maria Kostoula², Spyros Pournaras¹

¹Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, ²Attikon University Hospital, National and Kapodistrian University of Athens, Greece, Athens, Greece

**Background:** *Nocardia* spp. usually are Gram(+), slow-growing, opportunistic microorganisms, that cause rare and severe infections mainly in immunocompromised individuals.

**Materials/methods:** We analyzed the clinical and laboratory features in 56 patients affected by nocardiosis over 10 years (2009-2019) in the University Hospital of Athens "Attikon". We retrospectively reviewed the medical data of the patients with culture–proven *Nocardia* infection, including demographics, underlying diseases, antibiotic treatment and outcome. Species identification was performed by sequencing analysis of 16S rDNA (1500-bp) gene. Drug susceptibility testing was performed according to the CLSI recommendations and results were interpreted based on CLSI breakpoints [documents M24 and M62, 2018].

**Results:** We identified 56 patients (32 men, mean age 61.3 years), with clinical evidence of nocardiosis and one or more positive cultures from various specimens. Among these patients, 42 (75%) had a Physician’s high level of suspicion, 44 (78.6%) had an underlying immunosuppressive disease and 12 (21.4%) were immunocompetent. The most common underlying immunocompromising condition was hematological and solid tumor neoplasm (59%), followed by autoimmune diseases (18.1%). In this group, most of the *Nocardia* strains were isolated from the lungs (27/44) or from subcutaneous abscesses (17/44). In one patient, the same strain of *Nocardia* was isolated from bronchial and blood culture. In the group of immunocompetent, 9 patients had Chronic Obstructive Pulmonary Disease (COPD) with frequent pulmonary infections (8 patients and 1 from brain abscess). In the last 3 immunocompetent patients, *Nocardia* strains were isolated from subcutaneous tissue. *Nocardia* strains belonged to 9 species. *Nocardia cyriacigeorgica* was the most frequently isolated (35.7%), followed by *N. abscessus* (12.5%) and *N. farcinica* (10.7%). *Nocardia* strains were highly susceptible to trimethoprim-sulfamethoxazole, linezolid and amikacin [susceptibilities 94.6-100%] and highly resistant to ciprofloxacin [resistance 75%]. Treatment was based on susceptibility data (when available). Long–term prognosis was good, with a treatment success rate of 92.9%

**Conclusions:** Nocardiosis is a common opportunistic infection in patients with underlying immunosuppressive conditions or in patients with COPD and frequent pulmonary infections. In our study, trimethoprim-sulfamethoxazole remains effective in treating nocardial infections. High level of clinical suspicion, timely species identification and antimicrobial susceptibility tests may guide treatment.

**Presenter email address:** fankon68@gmail.com
Epidemiology and antifungal susceptibility of *Rhodotorula* spp. in a tertiary care hospital

Isabel Costales*1, Cristian Castelló-Abietar1, Helena M. Lorenzo Juanes2, Amparo Templado-Barroso1, Angel Ramirez1, Marta Sandoval1, Teresa Pelaez Garcia1

1Hospital Universitario Central de Asturias, Oviedo, Spain, 2Hospital Universitario de Salamanca, Salamanca, Spain

**Background:** *Rhodotorula* spp. have been recognised as emerging yeast pathogens in humans in the last two decades. While no cases of *Rhodotorula* infection were reported in the medical literature before 1985, the number of infections increased after that time, most likely because of the increase of immunocompromised patients and wider use of intensive treatments. Our aim was to evaluate the epidemiology and the antifungal susceptibility of *Rhodotorula* infection in our hospital during 5-year period

**Materials/methods:** Clinical reports of patients with *Rhodotorula* infection attended at our institution from 2015 to 2019 were included in the study. *Rhodotorula* spp were identified by MALDI-TOF MS. In vitro activities of amphotericin B (AMB), fluconazole (FZ), itraconazole (IZ), voriconazole (VZ), posaconazole (PZ), isavuconazole (ISV), anidulafungin (AND), caspofungin (CAS), micafungin (MYC) and terbinafine (TB) were determined by the broth microdilution method following CLSI criteria.

**Results:** During the study period, 125 isolates of *Rhodotorula* spp (125 patients) were isolated, being the distribution each year as follows: 2015 (18), 2016 (25), 2017 (35), 2018 (22), 2019 (23). From 125 cases, 4 (3.2%) were invasive mycoses (3 fungemia and one peritonitis) from onco-haematological patients (two solid tumors and two leukemias). The remaining sites of isolation were: skin 62 (49.6%), nails 31 (24.8%), wounds/abscess 12 (9.6%), conjunctival 4 (3.2%), ear 4 (3.2%), genital 4 (3.2%), oropharyngeal 3 (2.4%), and respiratory tract 1 (0.8%).

Globally, the antifungal susceptibility (range/geometric mean µg/ml) of 45 available *Rhodotorula* isolates, were as follows: AMB (0.25-1/0.605), FZ (8-128/44.121), IZ (0.06-2/0.591), VZ (0.03-2/0.508), PZ (0.015-1/0.344), ISV (0.03-0.5/0.137), AND (4-8/6.755), CAS (4-32/12.208), MYC (8-128/62.927) and TRB (0.125-32/7.476).

**Conclusions:** Invasive mycoses due to *Rhodotorula* is a rare clinical entity, but it has to be kept in mind in onco-haematological patients, due to its multiresistance profile. Amphotericin B and isavuconazole showed to be the most active antifungal agents.

Abstract 5360

**The Global Point Prevalence Survey of Antimicrobial Consumption and Resistance (Global-PPS): the results of antimicrobial prescribing in 33 hospitals in Guinea**

Mamadou Saliou Sow1,2,3,4*, Ann Versporten5, Ines Pauwels6, Djomo Stanislas Djiro7, Herman Goossens6

1Conakry, Conakry, Guinea, 2Donka, National Hospital, Conakry, Guinea, 3Service des Maladies Infectieuses, Hôpital National Donka, CHU Conakry, Faculté des Sciences et Techniques de la Santé, Conakry, Guinea, 4Donka, National Hospital, Conakry, Guinea, 5Laboratoire de microbiologie médicale, Institut de vaccination et maladies infectieuses (VAXINFECTIO), Faculté de médecine et sciences de la santé, Université d’Anvers, Anvers, Belgium, 6Laboratoire de microbiologie médicale, Institut de vaccination et maladies infectieuses (VAXINFECTIO), Faculté de médecine et sciences de la santé, Université d’Anvers, Anvers, Belgium, 7Département de Santé Publique, Faculté des Sciences et Techniques de la Santé, Conakry, Guinea

**Background:** Since 2015, Guinea is participating in the Global Point Prevalence Survey of Antimicrobial Consumption and Resistance (www.global-PPS.com). We aimed to evaluate the quantity and quality of antimicrobial prescriptions and resistance at 30 Hospitals in the Republic of Guinea

**Materials/methods:** A cross-sectional point prevalence survey (Global-PPS) was conducted in 2017 and 2018, including all adult and pediatric medical and surgical services in 33 different Guinea’s hospitals. Detailed data were collected for all patients receiving anti-infective agents present at 8.00 am on the day of the survey. Data included details on antimicrobial agents, reasons and indications for treatment as well as set of quality indicators. The information was extracted from the patient’s medical and nursing records. The missing data were supplemented by information obtained directly from the professionals in charge of the patients.

**Results:** Out of the 33 hospitals, 2834 patients were present in the facilities on the day of the PPS, of which 2107 (74%) were on at least one anti-infectious drug. Of the 3925 antimicrobial prescriptions, 80.6% (n = 3165) were systemic antibiotics, 16.7% were antiprotozoal. The most commonly prescribed antibiotics were ceftriaxone (n = 671) and metronidazole (n = 574). Community acquired infections were the main indication for the prescription of antibiotics (50%), followed by surgical prophylaxis (30.2%).

The medical prophylactic prescribing was (2.4%). Documentation of the reason for the prescription was written in 67.8% of the prescriptions, but a revision date was not documented.

Guidelines were missing in 33.2% of cases. If guidelines were existing, most antimicrobials were prescribed according to these (34.5%).

**Conclusions:** This study has shown high prevalence’s of antimicrobial use in hospitals in Guinea. We aim to draft a national policy against antimicrobial resistance and further develop a guide to the appropriate use of antibiotics in Guinea. As part of antimicrobial stewardship (AMS) programs, which will be crucial to develop, feedback of the Global-PPS results and education of the different hospitals will enhance creating global awareness amongst physicians and staff. We aim to repeat the Global-PPS after the initiation of these AMS programs.

Abstract 5363

Prevalence of and risk factors for extended-spectrum beta-lactamase genes carriernship in a middle-aged and elderly population-based cohort

Marlies Mulder1, Pascal Arp1, Djawad Radjabzadeh1, Jessica Kiefte-De Jong2, Andre Uitterlinden1, Corné H. Klaassen1, Robert Kraaij3, Wil Goessens1, Bruno Stricker1, Annelies Verbon*1

1Erasmus MC, Rotterdam, Netherlands, 2Leiden University - Campus Den Haag, Den Haag, Netherlands

Background: The increasing resistance to beta-lactam antibiotics is an alarming development worldwide. Especially the worldwide spread of CTX-M and other plasmid encoded β-lactamases such as TEM, SHV and CMY-variants contribute to the increasing resistance. The prevalence of these genes has been reported to vary between populations but only a few of these were studied in community-dwelling populations.

Materials/methods: We studied the prevalence of TEM, SHV, CTX-M and CMY genes in stool samples of middle-aged and elderly individuals of the Rotterdam Study, a population-based cohort. We isolated DNA from these samples, followed by RT-PCR using previously published primer and probe sequences. We calculated the prevalence of these genes in stool and studied the association with several potential risk factors, such as use of antimicrobial drugs, use of proton pump inhibitors, diet and factors describing the composition of the microbiota.

Results: From the studied targets, the gene with the highest prevalence was TEM (61.3%), followed by SHV (18.1%). The prevalence of the extended beta-lactamase genes CTX-M (5.3%) and CMY (3.5%) was relatively low. Use of proton pump inhibitors was associated with a higher prevalence of carriernship of TEM, SHV and CMY genes [TEM: OR 1.38; 95%CI 1.06-1.79; SHV: OR 1.93; 95%CI 1.44-2.57; CMY: OR 2.10; 95%CI 1.15-3.85]. There was an association between beta-lactamase resistant penicillin use and CMY carriernship, but no other associations between use of beta-lactam antibiotics and carriernship of these genes was found.

Conclusions: The prevalence of carriernship of TEM, was substantial, but the prevalence of carriernship of the extended-spectrum beta-lactamase genes CTX-M and CMY was low in this healthy population-based cohort. Interestingly, use of proton pump was associated with carriernship of three of these genes, whereas use of antimicrobial drugs showed little associations. Our approach is feasible in determining the prevalence of carriernship of known resistance genes and may be used to compare different populations. Further studies are needed to determine the role of the composition of the microbiota on the prevalence of resistance genes and to determine the linkage to specific micro-organisms.

Antimicrobial drug resistance, molecular typing and whole genome sequencing of *Salmonella enterica* serovar Derby from human clinical samples and pork products

Vanesa García Menéndez*1;2, Xenia Vázquez1;3, Raquel García-Fierro1, Paula Quirós1, Rocío Granda1, Cristina Cuervo1, María Margarita Bances4, María Rosaura Rodicio3;5, M. Rosario Rodicio1;3

1University of Oviedo, Área de Microbiología, Departamento de Biología Funcional, Oviedo, Spain, 2University of Santiago de Compostela, Departamento de Microbiología y Parasitología, Facultad de Veterinaria, Campus Lugo, Lugo, Spain, 3Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, 4Dirección General de Salud Pública, Laboratorio de Salud Pública (LSP), Consejería de Sanidad, Principado de Asturias, Oviedo, Spain, 5University of Oviedo, Departmento de Bioquímica y Biología Molecular, Oviedo, Spain

**Background:** *Salmonella* Derby is among the 10 most prevalent serovars of *S. enterica* in Europe and is the predominant serovar in pigs. Accordingly, it can be transmitted to humans through the food chain by consumption of pork-derived products. In the present study *S.* Derby isolates recovered in Spain from humans and pork products were investigated using traditional techniques and whole genome sequencing (WGS).

**Materials/methods:** Fifty-five *S.* Derby isolates collected between 2006 and 2018 from human clinical samples (26) and pork products (29) in a Northern Spanish region were characterized regarding to antimicrobial resistance, detection of mobile genetic elements (integrons, transposons and plasmids), and pulsed-field gel electrophoresis (PFGE). Besides, four representative isolates (2 from each source) were sequenced with Illumina and their sequences analyzed using “on line” bioinformatic tools.

**Results:** Thirty-nine isolates (71%) were resistant to at least one antimicrobial and 22 (40%) were multidrug-resistant, sharing nearly all of them (20 isolates) resistance to streptomycin (*aadA*), sulphonamides (*sul1*) and tetracycline (*tet(A)*). The *aadA* and *sul1* genes were located in a class 1 integron and Tn1721 was detected in 15 *tet(A)*-positive isolates. In relation to other resistant genes, *tet(B)* was associated with Tn10 in three tetracycline-resistant isolates and *bla*TEM-1 was identified in five ampicillin resistant isolates, one of them positive for Tn3. The Asp87/Asn substitution in GyrA was detected in isolates resistant to nalidixic acid. The characterized isolates displayed a high diversity of plasmid and PFGE profiles, with each of the PFGE profiles being common to human and pork isolates. The four sequenced isolates belonged to ST40 and carried the *Salmonella* Pathogenicity Island SPI-23 (both features associated with pig origin), and presented the fosfomycin resistance gene *fosA7*. A high number of prophages and virulence genes implicated in fimbriae biosynthesis were also identified. ColE10 plasmids, carrying *tet(C)*, were detected in two isolates, and an IncI1 ST134 plasmid was present in a susceptible isolate.

**Conclusions:** Molecular typing and WGS support that the same *S.* Derby isolates are circulating in pork products and humans in our region, a fact that calls for control measures to prevent further dispersion of this serovar through the food chain.

Abstract 5369

Characterisation of ceftobiprole’s cerebrospinal fluid penetration in patients with external ventricular drainage

Matteo Castaldello*, Michele Malla, Valeria Avataneo, Miriam Antonucci, Amedeo De Nicolò, Alberto Librizzi, Lucrezia Guadagnini, Fabio Turia, Antonello Di Paolo, Francesco Ceccherini, Laura Galeotti, Liana Signorini, Antonio D’avolio, Frank A. Rasulo, Nicola Latronico, Simone Piva

Background: Healthcare-associated meningitis (HAM) is associated with significant morbidity and mortality. HAM treatment is challenging because of antibiotics resistance and the difficulty to achieve a therapeutic dose of antibiotics in the CNS. Ceftobiprole is a novel broad-spectrum cephalosporin with excellent activity against multi-drug resistant (MDR) pathogens. Since ceftobiprole is bactericidal, well-tolerated and it has anti-biofilm activity, it could be useful in case of HAM. Nowadays there are no human studies concerning the penetration and the efficacy of ceftobiprole in the cerebrospinal fluid (CSF). The present study aims to fill these gaps in the literature.

Materials/methods: We enrolled 5 patients with and implanted EVD who received Ceftobiprole for other reasons than HAM, in a single-center pilot study. Exclusion criteria were: patients < 18, cephalosporine allergy, end-stage renal insufficiency, BMI >30, pregnancy and end-stage diseases. We have measured the ceftobiprole concentration in 8 blood samples and 11 CSF samples from each patient (95 samples in total), as described at www.coqualab.it. We calculate the maximum serum (Cmax-s) and CSF concentration (Cmax-csf) and the percentage of CSF penetration of ceftobiprole, after the third infusion of Ceftobiprole (500mg e.v. every 8hr).

Results: The mean Cmax-s was 12.02 mg/L, reached after 2hr from drug infusion, whereas the mean Cmax-csf was 0.6 mg/L. In Figure 1 the mean concentrations [and the relative standard deviations] of serum and CSF ceftobiprole concentration for each time point are represented. The mean Ceftobiprole CSF penetration was 15.3%.

Conclusions: For the first time we studied the CSF ceftobiprole’s penetration in humans, founding a mean value of 15.3%. Although we cannot conclude anything about the Ceftobiprole CSF efficacy, its meningeal penetration is in line with other cephalosporines and it is higher than Vancomycin, posing the base for a possible role of Ceftobiprole in HAM treatment.

![Figure 1: Mean serum and CSF ceftobiprole concentration in the five patients studied, with the relative standard deviation. It is possible to note either the lower CSF concentration (15.3%) and the lower variability of CSF concentration. To: steady-state, before ceftobiprole administration, at the third dose; T1-T10 are respectively at 2-2.5-3-4-4.5-5-6-8-10-12 hours after ceftobiprole administration.](image)

Abstract 5374

**Insights in the resistome of multidrug-resistant *Pseudomonas aeruginosa* strains isolated in Romania from nosocomial infections and wastewater**

1University of Bucharest, Faculty of Biology, Microbiology Department, Research Institute of the University of Bucharest, Bucharest, Romania, 2University of Bucharest, Faculty of Biology, Microbiology Department, Research Institute of the University of Bucharest, Bucharest, Romania, 3University of Bucharest, Faculty of Biology, Genetics Department, Research Institute of the University of Bucharest, Bucharest, Romania, 4National Institute for Infectious Diseases ‘Matei Bals’, Bucharest, Romania, 5Synevo Central Laboratory Medicover, Bucharest, Bucharest, Romania

**Background:** Hospitals generate an impressive amount of wastewater per day, the hospital effluents being loaded with pathogenic microorganisms, antibiotics and pharmaceutical or toxic substances, which are partially removed during wastewater treatments, contributing to the pollution of the natural environments, including selection and dissemination of antibiotic resistance (AR). We aimed to examine the antibiotic resistant genes (ARGs) in multidrug resistant *Pseudomonas aeruginosa* (MDR *Pa*) strains isolated in the same temporal sequence from hospital infections (HI) and hospital sewages (HS) from Bucharest, the capital city of Romania.

**Materials/methods:** *Pa* strains were isolated in the same temporal sequence, plated on carbapenem and third generation cephalosporin supplemented culture media were identified using automatic and genetic methods and their resistance profiles (RPs) were investigated by disc-diffusion, automatic, and chromogenic methods. Selected strains were subjected to whole genome sequencing (WGS) (Illumina MiSeq pair end sequencing). For bioinformatic analyses SpaDES, ResFinder MLST and CARD Database were used.

**Results:** Following the RP results, a total of 30 MDR *Pa* strains were isolated and screened for the presence of ARGs. WGS revealed that one HI *Pa*, two Pa from the effluent (EF) and one from influent (IN) of the HS were assigned to ST 357 clone harboring *bla*IMP-13, *bla* OXA-10, *bla* VEB-9, and additionally the aminoglycoside ARGs aac(6’)-I1, aadA1 and ant(3’)-Ia, tetracycline resistance tet[A], ciprofloxacin resistance crpP1, qacEdelta1 (efflux), trimethoprim resistance drfB2 and sulphonamide resistance sul1. Another two Pa ST 357 from HS EF were positive for a different ESBL gene, i.e. *bla* VEB-1. Pa assigned to ST 62 isolated from HS IN harbored *bla* IMP-13, *bla*OXA-494, *bla* PDC-55, and additionally, sul1 and fosA. Three HI Pa strains were assigned to the high-risk sequence type ST 233, harboring *bla* VIM-2, *bla*GES-1 (n=2)/*bla* VEB-9 (n=1) (additional ARGs: crpP-1, tetG, sul1, cmlA6, drfB5, drfA6, qnrVC1, aph(3’)-Iib, aadA2 and ant(3’)-Ia) and one HI Pa to the ST 395 clone (*bla* OXA-488, *bla* PDC-113, aph(3’)-Iib and fosA).

**Conclusions:** We report here the first comparative description of the genetic background of AR in MDR *Pa* high risk clones circulating between the hospital wastewater and the hospital environment in Bucharest, Romania.

Abstract 5376

**Endemic extended-spectrum beta-lactamase-producing *Klebsiella pneumoniae* ST48 in a hospital setting and genomic plasticity driven by transposable elements**

Minh Nguyen Ngoc*, Friederike Maechler, Juan Pablo Rodriguez Ruiz, Basil Britto Xavier, Christine Lammens, Herman Goossens, Petra Gastmeier, Surbhi Malhotra-Kumar

1Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, University of Antwerp, Antwerpen, Belgium, 2Charité University Medicine, Berlin, Germany, 3Antwerp University Hospital, Edegem, Belgium

**Background:** Multidrug resistant (MDR) *Klebsiella pneumoniae* (*Kp*) are leading causes of severe hospital-acquired infections. Here, we report an endemic MDR *Kp*-ST48-clone with multiple chromosomally integrated copies of *blaCTX-M-15* (*Chr-blaCTX-M-15*) from a tertiary hospital in Berlin, Germany.

**Materials/methods:** From 2014-2016, we conducted a retrospective study in 8 wards of the hospital within a larger European study involving 4 countries. Rectal swabs were collected from patients at admission, weekly during hospitalization, and at discharge. Extended-spectrum beta-lactamase-producing *Kp* (*ESBL-Kp*) was isolated (CHROMID ESBL, BioMérieux, France) and identified (MALDI-TOF). Antimicrobial susceptibility to 15 antibiotics was determined by disk diffusion (Rosco, Denmark), E-test (BioMérieux, France), and CarbaNP using EUCAST-2019 breakpoints. During the study period, 49 ESBL- *Kp* were isolated from 46 patients across the 8 wards. Short- and long-read sequencing was performed on these ESBL- *Kp* using MiSeq (Illumina Inc., USA) and PacBio Sequel II (Pacific Biosciences, USA), respectively. Subsequent analyses were performed using an in-house bioinformatics pipeline (Bacpipe v.1.2.6), and ISFinder. Phylogenetic analysis was performed on core-genome SNPs using ME-GA-X and pairwise SNP distances were calculated using CLC Genomics Workbench v.9.5.1 (Qiagen, Germany). The presence of *Chr-blaCTX-M-15* genes was validated by long-range PCR using in-house designed primers.

**Results:** A total of 14 ESBL- *Kp* belonging to ST48 were isolated from 14 patients residing in 2 wards. All these strains were MDR defined by ECDC as non-susceptibility to at least 1 agent in ≥3 antimicrobial categories (Figure A). The first and the last ESBL- *Kp*-ST48 strains were isolated 535 days apart with only 16 SNP differences, suggesting the circulation of a single endemic clone in these wards. Core-genome SNP analysis revealed three clusters with a maximum of 20 intra-cluster SNP differences. A total of 7 regions of plasticity (RGPs) were identified (Figure B). Two to five copies of *Chr-ISEcp1-blaCTX-M-15* were found in these RGPs. Amongst the 14 clonal strains, one (P125A, Figure-A) was resistant to ertapenem and was isolated from a patient who received meropenem therapy. Resistance was due to IS1R-mediated *ompK36*-gene-inactivation.

**Conclusions:** Our results highlight the remarkable genomic plasticity, evidenced by multiple IS element integrations, and the persistent circulation of the ESBL-*Kp*-ST48 clone in a hospital setting.
Figure. (A) Phylogenetic tree constructed by Maximum Likelihood method based on 2142 core genome SNPs between 14 studied ESBL Kp ST48 strains and three publicly available reference strains (ERR025104, ERR025108 and ERR1740561), only bootstrap values >70% were shown. Strain clusters were defined as strains with ≤21 core-gene SNP differences. The presence and absence of the region of plasmidic (RGP), with 5 RGP contained blaCTX-M-15 (RGP1, RGP2, RGP4, RGP5, RGP6), are depicted by green and red cells, respectively. Antimicrobial susceptibility of studied strains were interpreted according to EUCAST-2019 breakpoints, susceptibilities indicated by light-green cells and resistances indicated by light-red cells. AM: Amoxicillin, XL: Amoxicillin-climoxil, CT: Cefotaxime, XM: Cefuroxime, TZ: Trimethoprim/Sulfamethoxazole, CL: Chloramphenicol, CI: Ciprofloxacín, NX: Norfloxacin, GM: Gentamicin, FM: Fosfomycin, MP: Meropenem, ETP: Ertapenem, IP: Imipenem, TC: Tetracycline (B) Seven RGP contained resistance genes (red) and mobile genetic elements (green); chromosomal genes are represented in blue.

**Abstract third-party references:** Supported by Hospital Clinic, IDIBAPS

**Background:** Epidemiological changes in infective endocarditis (IE) have been described in the 21st century. There is an increase in complexity, nosocomial or healthcare-associated acquisition and more involvement of vascular prostheses and cardiovascular implantable electronic devices (CIED). We aimed to describe the epidemiological and clinical changes and outcomes of CIED-IE in a reference center during the last 40 years.

**Materials/methods:** Retrospective analysis of prospectively collected CIED-IE cases from 1979 to 2018. Only definite CIED-IE cases were included (Duke criteria). Clinical and microbiological characteristics and outcomes (mortality, surgery) were analyzed comparing the period of diagnosis (1979-1999 vs. 2000-2018) and whether or not the patients had the device removed.

**Results:** Of 1,605 IE cases, 147 (9%) were CIED-IE. 21 episodes [3%] in 1979-1999 and 126 [13%] in 2000-2018 [p <0.001]. The distribution between pacemakers, defibrillators and cardiac resynchronization therapy was 75%, 24% and 1%, respectively. In the recent period, there were significantly more transfers, nosocomial infections, and fewer lead-vegetations. Staphylococci were the most frequent causative microorganism in both periods, but in the latter, there was a greater proportion of Streptococcus, Enterococcus, non-HACEK gram-negative bacilli and negative culture. CIED was removed in most patients [90.5% first period and 84.1% second]. There were no differences in-hospital mortality and one-year follow up between both periods but the recurrence rate was higher in the second period. Patients without device removal were significantly older [76 vs. 66 years, p <0.01] and had more recurrences [16% vs. 2%, p = 0.12]. The extraction of CIED was the only factor associated with a higher hospital mortality [10% vs. 44%, p <0.01] and at one year follow up [16% vs. 59%, p <0.01].

**Conclusions:** There were important epidemiological and clinical changes in CIED-IE in the last 40 years. In the last two decades there was an increase of lead-associated IE in patients with defibrillators and cardiac resynchronization therapy and an important proportion of cases were health-care related. Staphylococci was the most common etiological agents in both periods. Overall mortality was 14% and CIED extraction reduced relapses and was the only variable associated with survival.

**Table 1.** Comparison of CIED-IE cases by period and by surgical treatment (removal or non-removal)

Background: Pseudomonas aeruginosa (PA) is a water-associated, environmental pathogen frequently implicated in nosocomial infections. PA is known to exhibit a wide range of resistance mechanisms, including carbapenemase production. We encountered a cluster of PA isolates harboring blaVIM (VIM-PA) and sought to describe the clinical characteristics, outcomes, and infection control strategies associated with these infections.

Materials/methods: A total of 12 patients with positive cultures for VIM-PA were identified between 12/2018-06/2019. An infection control bundle was introduced to decrease horizontal transmission. Measures included: changing sink P-traps, installing point-of-use sink filters (changed bimonthly), cohorting patients, and decreasing the nurse-to-patient ratio. A reflex-testing algorithm was implemented in the microbiology laboratory to enhance rapid identification and improve antimicrobial stewardship. Testing methodology for carbapenemase genes was modified from CarbaNP to Carba-R PCR. A new surveillance protocol allowing for timely identification of new cases, early provider notification, and immediate contact isolation was implemented. Mechanism based susceptibility testing (MBST) using combination antimicrobial double and triple disk diffusion assays guided therapy.

Results: Nine patients developed infections with VIM-PA, three of which were identified retrospectively. Three additional patients were colonized with PA. The median age was 63.6 (IQR 51 -74) years and the average length of stay was 37.8 days. Nine patients were admitted from home; three transferred from nursing homes. Organisms were isolated from the respiratory tract (59%), urine (9%), rectal surveillance (16%), and wound (16%) cultures. MBST was successful in identifying an effective antibiotic combination regimen against VIM-PA among prospectively identified patients (n=6). Four patients were treated with a regimen consisting of ceftazidime/avibactam, aztreonam, and polymyxin b (Figure 1). Three had follow-up cultures. One patient with urosepsis had microbiological clearance. Two patients with pneumonia had persistent colonization despite clinical improvement. No patients died from infection and incident cases did not emerge over the following five months.

Conclusions: We describe a cluster of VIM-PA encountered in Miami. Until recently, there was no single effective antimicrobial on the market for this organism. We report success utilizing rapid identification and MBST to guide combination therapy, resulting in low attributable mortality. An infection prevention control bundle was successful in preventing further transmission.

Abstract third-party references: GAMES study group

Background: Mural endocarditis (MIE) is a rare but severe condition. There are no published MIE series and information about its characteristics and outcome is scarce.

Materials/methods: Consecutive patients with IE according to Duke criteria were prospectively included in the registry “Spanish Collaboration on Endocarditis (GAMES)” between January 2008 and December 2017 in 35 Spanish hospitals. Multidisciplinary teams completed a standardized case report form. Patients with mural endocarditis (endocarditis involving non-valvular native endocardium) were analysed and compared with patients with valvular (VIE) or device-associated (DIE) endocarditis in the database.

Results: During the study period, 28 cases out of 3830 fulfilled the inclusion criteria (0.7% of IE during the same period). Vegetations were more frequently located in the right heart (atrium 46.4%, ventricle 10.7%, ventricular outflow tract 10.7%, superior cava vein 10.7%) than in the left heart (atrium 10.7%, ventricle 3.6%, ventricular outflow tract 3.6%) or other (persistent ductus 3.6%).

The most frequent etiology was staphylococcal (32%), followed by Streptococci and fungi (25% each), Enterobacteriaceae and polymicrobial (7% each) and Enterococci (4%).

When compared with VIE or DIE endocarditis, patients with MIE were younger (median age 59y [46 - 57] versus 69 [57 – 77], p <0.01). Transplant and hemodialysis were more common (12.9% versus 1.7% and 12.9% versus 4.3%, p<0.01 and p=0.008 respectively) and Charlson comorbidity index was lower (4 [2 - 6] versus 5 [3 – 7], p=0.06) among them. Endocarditis originated in catheters was significantly more frequent among patients with MIE (57% versus 9.6%, p <0.01) and right heart endocarditis was more prevalent (85.7% versus 15.2%, p <0.01). Surgery was indicated less often (35.7% versus 66.8%, p<0.01), but therapy was longer (42 (30 - 52) versus 38 (25 – 45), p= 0.01).

In-hospital mortality and one-year mortality were similar to that of VIE and DIE.

Conclusions: Mural endocarditis accounts for 0.7% of endocarditis. It is often a complication of catheter use and usually involves right heart. It appears in immunocompromised patients and fungal etiology is common. Surgery is less commonly indicated, but medical therapy is longer, to achieve a similar mortality.

Lamb meat as a source of dissemination of cephalosporin-resistant Escherichia coli

Katia Suemi Gozi, Luana Deus Ajude, Leticia Kalir Pradela*, Marlon Barroso, Caroline Silva, Mara Nogueira, Tiago Casella

1Faculdade de Medicina de São José do Rio Preto - FAMERP, Sao Jose do Rio Preto, Brazil, 2Centro Universitário de Rio Preto - UNIRP, Sao Jose do Rio Preto, Brazil, 3Hospital de Base de São José do Rio Preto, Sao Jose do Rio Preto, Brazil

Background: The presence of Escherichia coli in food suggests faecal contamination, and indeed several studies have reported the transmission of bacteria and antimicrobial resistance genes through the food chain. Third-generation cephalosporin (3GC)-resistance is an important threat to public health, and bacteria presenting such phenotype points out to the transmission of resistance genes from and to the intestinal microbiota. Antimicrobial resistant bacteria from sheep are a still neglected field in Brazil despite the exponential increase in the meat consumption. Thus, this study aimed to characterize the 3GC-resistant E. coli isolated from lamb meat.

Materials/methods: Twenty-five retail lamb meat were purchased in the State of São Paulo, Brazil, and analyzed with 4 mg/L ceftiofur as selective agent. Suggestive colonies of E. coli in MacConkey agar were identified and submitted to antimicrobial susceptibility test by disk-diffusion or broth microdilution. Genes responsible for 3GC-resistance and 27 virulence genes were screened by PCR. bla-carrying plasmids were characterized. Isolates were typed by phylogenetic group, XbaI-PFGE and MLST.

Results: Twenty-six E. coli were isolated from 60% of federal service inspected lamb meats, and 13 harboured IncI1-bla_{CTX-M-8} plasmids [73 kb to 97 kb] as responsible for 3GC-resistance. Ten isolates harboured IncHI2-bla_{CTX-M-2} plasmids [242.5 kb to 290 kb], two presented the bla_{CTX-M-55} in a not typed plasmid (< 48.5 kb), and one carried a bla_{CTX-M-14} in a not typed plasmid (97 kb). The majority of isolates was considered commensal, but one carried the vat gene of extraintestinal pathogenic E. coli. The XbaI-PFGE revealed general dissimilarity among isolates, with exception of four clusters formed by isolates recovered from different samples originated from animals slaughtered at the same slaughterhouse. The MLST also revealed the majority as commensal bacteria, with exception of the potentially pathogenic lineages ST58, ST106, ST117, ST205, and ST349.

Conclusions: Genes and plasmids responsible for 3GC-resistance in E. coli from lamb meat are the ones also prevalent in food-producing animals in the country, which supports that intestinal bacteria in animals could contaminate the ensuing products. This study also demonstrated slaughterhouses as a source of meat contamination by 3GC-resistant E. coli.

Abstract 5390

Invasive pneumococcal disease among adults in Germany, nine years after PCV13 introduction

Mark Van Der Linden*1, Andreas Itzek1, Stephanie Perniciaro2, Matthias Imöhl1

1University Hospital RWTH Aachen, Department of Medical Microbiology, German Nationale Reference Center for Streptococci, Aachen, Germany, 2Yale School of Medicine, Epidemiology of Microbial Diseases, New Haven, United States

Background: Streptococcus pneumoniae remains a leading cause of infectious disease among children and the elderly. In July 2006, vaccination with pneumococcal conjugate vaccine was generally recommended in Germany for all children ≤24 months. Apart from a strong direct effect, pneumococcal conjugate vaccination has shown herd protection effects among non-vaccinated children and adults.

Materials/methods: The GNRCs has monitored the epidemiology of IPD in adults in Germany since 1992. All isolates were serotyped using the Neufeld Quellung reaction.

Results: Since 2006/2007, the amount of IPD isolates sent to the GNRRCS has steadily increased from 2000 to over 3000 per season. Before childhood PCV vaccination, 40-45% of IPD cases among adults were caused by PCV7 serotypes. After the start of childhood vaccination, this percentage was gradually reduced to 5.4% in 2018-2019. In 2009, higher valent vaccines [PCV10, PCV13] were introduced among children. Among adults, a reduction of the percentage of IPD caused by the six additional serotypes from 42.1% in 2010-2011 to 28.0% in 2014-2015 was observed, and percentage has remained stable until 2018-2019 (30.2%). In the last five seasons, PCV13 serotypes, 3, 4, 19F and 19A have remained at prevalences over 1%. In 2018-2019, prevalences were 20.3% [3], 2.1% [4], 3.7% [19A] and 1.5% [19F], whereas 19A has slightly decreased in the last season. Serotype 4 has increased and 19F and 3 have remained stable. The prevalence of serotype 3 has reached its highest point ever since the introduction of PCVs. Among non-PCV13 types, 8 [14.0%], 22F [7.2%], 9N [6.4] and 12F [5.0%] are most prevalent. New PCV formulation would have a theoretical coverage of 38.7% [PCV15 and 65.2% [PCV20].

Conclusions: The herd protection effect of PCV7 and PCV13 on serotype distribution of IPD among adults in Germany has reached its limit. PCV13 serotypes have remained at a prevalence of about 30% during the last five seasons. Serotype 3 shows no herd protection, with prevalence increasing to 20.3% in 2018-2019. The data implicate circulation of PCV13 serotypes among adults, which might only be interrupted by direct vaccination.

Abstract 5391

Comprehensive analysis of evolutionary dynamics of circulating strains and immunopathogenesis of respiratory syncytial virus-associated acute lower respiratory tract infections in children

Subhabrata Sarkar1*, Radha Kanta Ratha1, Meenu Singh1, Amarjeet Singh1, Mini P. Singh1

1Post Graduate Institute of Medical Education & Research, Chandigarh, India

Background: The study aimed to explore the role of circulating genotypes, evolutionary dynamics, viral load and host cytokines in RSV mediated ALRTI.

Materials/methods: NPAs were collected from children (n=349) between December 2013-March 2017. RSV positive samples were subjected for viral load estimation by RT-PCR. IL-17A, IFN-Ɣ, TNF-α, IL-10, IL-6 levels in NPA samples were determined by CBA and MMP-9 and TIMP-1 levels by ELISA. The viral load and cytokine levels were correlated with the WHO criteria for ALRTI severity. ‘G’ gene region of RSV (n=77) was sequenced for phylodynamics analysis. Potential N-glycosylation and O-glycosylation sites and Selective pressure were predicted.

Results: RSV positivity was 41.38% (146/349). Of 59 RSV-A strains, 58 belong to RSV A ON1 genotype with 72 bp nucleotide (24aa) duplication. AA mutation analysis identified four most frequented mutations in duplicated region, E295K (42.1%; 24/57) followed by G284S (36.84%; 21/57) and V303A/I (28.07%; 16/57). Evolutionary rate of RSV A ON1 strains was 5.29X10⁻³ substitution/rate/year. The ON1 strains studied were seen to be sharing a similar profile of O-glycosylation sites and contained 40—50 O-glycosylation predicted sites and the 24 AA duplication resulted in 8 potential O-glycosylation site introduction in the duplicated site. Two codon sites were under positive selection pressure L310P by SLAC method and L298P by IFEL method and comparison with NIV1114046 strain isolated from Pune, India, observed that only a single codon was found to be under positive selection pressure L310P by SLAC method and L298P by IFEL method and with 60bp nt duplication in the second hypervariable region of G gene. The RSV viral load of severe ALRTI patients was significantly higher than the ALRTI patients. Pro-inflammatory cytokine TNF-α level [p<0.001], IL-6 [p<0.01] and MMP-9 was secreted in significantly higher levels in severe ALRTI patients than ALRTI patients [<0.001] leading to higher MMP-9/TIMP-1 ratio in severe ALRTI patients [p<0.001].

Conclusions: This comprehensive study on the phylodynamics of circulating RSV strains in Indian subcontinent. The study highlights Th2 cytokine bias in the pathogenesis of RSV disease with the possible contribution of MMP-9 towards disease severity.

Leptospira spp. in rodents and environmental samples from Lisbon and Setubal districts (Portugal): what are the risks for public health?

Maria Do Rosario Oliveira Fernandes*, Filipe Delgado, Teresa Carreira, Rosa Teodósio, Maria Luísa Vieira

1Global Health and Tropical Medicine (GHTM), Institute of Hygiene and Tropical Medicine (IHMT), Universidade NOVA de Lisboa, Lisbon, Portugal, Lisboa, Portugal, 2Universidade NOVA de Lisboa, Lisbon, Portugal, Global Health Tropical Medicine [GHTM], Institute of Hygiene and Tropical Medicine [IHMT], Lisbon, Portugal

Abstract third-party references: Leptospirosis and Lyme Borreliosis laboratory, Medical Microbiology Unit, Global Health and Tropical Medicine [GHTM], Institut of Hygiene and Tropical Medicine (IHMT), Universidade NOVA de Lisboa (UNL), Lisbon, Portugal, Tropical Clinic Unit

Background: Leptospirosis is an infectious zoonotic disease of worldwide importance. Rodents are the most common reservoirs in Leptospira spp. dissemination. When excreted in the urine, spirochetes can survive for several weeks or months under favorable conditions (wet soil, water with neutral or slightly alkaline pH). Thus, contaminated water and soils become essential vehicles of transmission to humans, which can be infected by penetration of these infectious agents into intact mucous membranes (nose, mouth, eyes), or to healthy or injured skin. Thus, this study aimed to evaluate the presence of Leptospira spp. in soils, freshwater collections, and rodents from two districts of Portugal mainland (Lisbon and Setubal).

Materials/methods: Environmental samples (N=250), of which 161 were obtained from different freshwater collections (surface of lakes, rivers, and public fountains), and 89 soil samples (near freshwater collections, dustbins, or wooded areas) were collected in nine cities from Lisbon and Setubal districts. At the collection sites, chemical and physical parameters (e.g., pH, nitrates, temperature) were evaluated. In parallel with environmental samples, it was trapped rodents (N=18) for the analysis of blood, urine, and organs (kidneys, liver, spleen, and lungs).

After DNA extraction from all samples, two nested-PCR protocols with different primers were used. At first, it was applied a nested-PCR protocol with universal primers from the rrs (16S) gene, for Leptospira spp. detection. Each sample with leptospiral DNA amplification was submitted to a second nested-PCR protocol, with specific primers (targeting lipL32 gene) for detection of pathogenic species.

Results: Assessment with “LipL32” protocol, revealed pathogenic Leptospira DNA in 38+/100 water samples (38%), 7+/75 soil samples (9%) and in 14 rodents (78%), being observed that the kidneys (n=13+/14; 93%), liver, and lungs (n=12+/14; 86%) were the more colonized organs. No Leptospira DNA was detected in any blood samples.

Conclusions: The amplification of Leptospira spp. DNA in more than half of the rodents and water samples, as well as in the majority of soil samples, represents a disturbing result, leading to a significant public health concern about the risk that it poses to population health.

The necessity of testing for diarrhoea-causing intestinal parasites on broad indications

Gitte Nyvang Hartmeyer*1, Silje Vermedal Hoegh1, Michael Kemp1

1Odense University Hospital, Department of Clinical Microbiology, Odense, Denmark

Background: Testing faecal samples for parasites have traditionally been done by microscopy. The limited capacity of this technology has necessitated strict indications for testing, mostly severe immunosuppression or travel history. Many laboratories have now replaced microscopy by molecular techniques, which are more sensitive and economical affordable, and allow high throughput in a short time. Access to molecular testing allows implication of a less restricted visitation of samples and calls for a re-evaluation of which patients to test for intestinal parasites.

Materials/methods: 5006 stool samples from 2249 patients (on average 2.2 samples per patient) were examined for Giardia duodenalis, Cryptosporidium species and Entamoeba histolytica from 5th November 2017 to 4th November 2018. The investigation was performed by microscopy and strict visitation (specific requisition, a history of diarrhoea > 14 days, travel outside Europe or immunosuppression). 5686 stool samples from 4706 patients (on average 1.2 samples per patient) were examined for the same three parasites from 5th November 2018 to 4th November 2019. The investigation was performed by RT-PCR and broad visitation (specific requisition, all children <17 years old, macroscopic watery stool samples, a history of travelling, bloody diarrhoea or immunosuppression).

Results: The rates of patients with G. duodenalis increased from 0.4 % to 0.8 %, and patients with Cryptosporidium spp. increased from 0.2 % to 1.5 %. The total number of tested samples/patients and detected parasites are shown in table 1.

Conclusions: Replacing microscopy by species-specific RT-PCR and introducing a broader visitation, more than doubled the number of patients tested with only a small increase in the total number of tests. The positive rate for G. duodenalis was doubled and for Cryptosporidium spp. it was seven times higher in the samples tested. It shows very clearly that there is a need for an extended visitation than most frequently used in the investigation of diarrhoea-causing intestinal parasites.

Abstract third-party references: REIPI (Red Española de Investigación en Patología Infecciosa), Instituto de Investigación "i+1", Hospital 12 de Octubre, GEIO-SEIMC (Grupo de Estudio de Infeccion Osteoarticular - Sociedad Española de Enf. Infecciosas y Microbiología Clínica)

Background: The prognosis of OAI caused by QR-GNB is poor, especially when an orthopaedic device (OD) is retained or when caused by MDR/XDR microorganisms. C+BL could be an effective alternative treatment, but experience is lacking. Our aim was to prospectively assess the safety and efficacy of this antimicrobial regime.

Materials/methods: Prospective (February 2018-September 2019), observational, multicentre (14 hospitals), non-comparative study of patients with OAI caused by QR-GNB treated with C+BL after surgery (if indicated). The primary outcome was the absence of clinical relapse or persistence due to the same QR-GNB.

Results: 45 patients were included (median age 73y [IQR 52-79]; 51% women; Charlson 1[IQR 0-2]). Thirty-three cases (73%) involved OD: 18 prostheses and 15 osteosynthesis; the rest were 9 osteomyelitis and 3 arthritis (table). Median treatment duration was 42d (IQR 36-53), it being with C+BL during 28d (IQR 22-36). Most-employed β-lactams were meropenem (40%), ceftazidime (24%), ceftriaxone (18%) and piperacillin-tazobactam (7%), administered as continuous/extended infusion in 22 cases (49%). Toxicity led to treatment withdrawal in 13 patients (29%), it being always reversible. Colistin-related toxicity happened after median treatment duration of 16d (IQR 7-24) in 9 patients (20%): renal-failure (AKIN≥1) in 6 (13%), neurological in 2 (4%) and digestive in 1 (2%). It was associated with higher drug plasmatic levels (2.2mg/L -vs- 1.0mg/L, p<0.001). β-lactam-related toxicity occurred in 7 episodes (16%): neurologic in 3 (7%), hematologic, digestive, dermatologic and renal in 1 (4%) each. Seven (16%) cases were not-evaluable: 3 (7%) are under-treatment, 3 (7%) due to not-related-to-infection-death and 1 (2%) lost to follow-up.

Absence of microbiologic-failure was reported in 37 cases (82%, CI95% 69-91%) in the overall cohort, after a median follow-up of 190d (IQR 99-320). Non-failure by subgroups: OD-retention 13/16 (81%); MDR/XDR 21/26 (81%); non-MDR/XDR 16/19 (84%).

Conclusions: Our preliminary data shows C+BL to be an effective treatment for complex OAI caused by QR-GNB, including MDR/XDR strains and the need for OD retention. Toxicity is a concern but seems to be reversible and potentially preventable by colistin concentration monitoring.

**Polymyxin B broth disk elution as a screening test to determine polymyxin B susceptibility in Enterobacterales**

Naiany Cielo¹, Tanise Belmonte¹, Mariana Preussler Mott², Gabriela Rosa Da Cunha¹, Neidimar Tolfo², Cezar Vinicius Würdig Riche*²,³, Ravena Maya Cardoso Da Silva¹, Otávio Hallal Ferreira Raro², Cicero Dias¹, Juliana Caierao¹

¹Federal University of Rio Grande do Sul, Porto Alegre, Brazil, ²Ernesto Dornelles Hospital, Porto Alegre, Brazil, ³Federal University of Health Science of Porto Alegre, Porto Alegre, Brazil

**Background:** Infections caused by carbapenem-resistant Enterobacterales are challenging and treatment may be restricted to limited drugs, including polymyxins. Detection of susceptibility to polymyxins is a nightmare due to physicochemical properties of the drug. EUCAST recommends Broth Microdilution (BMD) as reference method. However, it is a laborious and expensive technique. Polymyxin B Broth Disk Elution (PBDE) test, based on the elution of the polymyxin B disk content, is an easy and cheap methodology. We aimed to evaluate PBDE accuracy as a screening test.

**Materials/methods:** 196 non-duplicated Enterobacterales including mainly *K. pneumoniae* (88.6%) were tested. Minimal Inhibitory Concentration (MIC) of polymyxin B was defined by BMD and interpreted according to EUCAST. PBDE was performed in duplicate using a 300 IU-polymyxin B disk eluted for 30 minutes at room temperature on 15 mL of cation-adjusted Mueller-Hinton Broth (final polymyxin B concentration: 2 µg/mL). After elution, 75 µL of 0.5 McFarland bacterial suspension was added (final concentration 7.5 x 10⁵ UFC/mL) and tube was incubated for 16-20h. A tube containing only broth (growth control) was used for each isolate. Visual growth of bacteria indicated positive result (MIC > 2 µg/mL). A subset of 40 resistant isolates were tested using shorter periods of incubation (6h, 7h and 8h).

**Results:** Polymyxin B MICs varied from 0.125 to >64 µg/mL, with 34 (17.3%) presenting borderline MICs (2 and 4 µg/mL). Ninety (45.9%) were resistant to polymyxin B. PBDE demonstrated 98.9% of sensitivity and 100% of specificity when standard incubation time was applied. One *K. pneumoniae* presenting MIC 4 µg/mL gave negative result in PBDE. Shorter incubation reduced sensitivity (57.5%, 67.5% and 82.5% after 6h, 7h and 8h, respectively). However, when excluding isolates presenting MICs borderline (4 µg/mL), sensitivity increased significantly (65.6%, 78.1% and 96.9% after 6h, 7h and 8h, respectively).

**Conclusions:** PBDE proved to be a cheap, easy to perform and accurate screening test for determining polymyxin B susceptibility in Enterobacterales. Reduced incubation compromised sensitivity although it seems to be dependent of MIC values. Moreover, the limited number of isolates tested (n=40) may had influenced the sensitivity.

Abstract 5402

**Retrospective study of cytomegalovirus infection in orthotopic liver transplantation recipients receiving low dose valganciclovir prophylaxis**

Mary Lucey*, Suzy Fitzgerald1, Sinead Mcdermott1

1St Vincent’s University Hospital, Dublin, Ireland

**Background:** Prophylaxis with valganciclovir has shown efficacy in reducing the rate of cytomegalovirus (CMV) infection post solid organ transplantation (SOT), although there is a lack of consensus regarding optimal use and dosing in liver transplantation. Some centres advocate a low dose prophylaxis regimen of 450mg once daily to reduce complications related to myelosuppression. The aim of the study was to demonstrate the rate of CMV DNAemia in the context of universal low dose valganciclovir prophylaxis and evaluate the timing and severity of CMV infection when it occurred.

**Materials/methods:** A retrospective study was carried out in the National Liver Transplant Unit, St Vincent’s University Hospital, Dublin between 2017 and 2018. Data was collected from clinical charts and the laboratory information management system.

**Results:** 63 orthotopic liver transplantations (OLT) were performed between 2017 and 2018. 13 patients (21%) experienced CMV DNAemia post OLT; 3 donor positive, recipient negative (D+/R-), 4 D-/R+ and 3 D+/R+. One D-/R- patient, who did not meet criteria for prophylaxis with valganciclovir, experienced primary CMV infection. Seven patients had early CMV DNAemia (within three months of transplant). Eleven patients experienced uncomplicated asymptomatic DNAemia. One patient (D-/R+), experienced biochemical hepatitis coincident with a high CMV viral load although liver biopsy did not confirm CMV disease. Two patients with CMV DNAemia died. In one, the cause of death was bowel ischaemia. The second patient, (D-/R+) had common variable immunodeficiency syndrome with profound immunosuppression, experienced prolonged CMV DNAemia and died of pneumonia.

**Conclusions:** No high risk (D+/R-) patient developed CMV disease. CMV infection was observed in two patients, both D-/R+, (one late onset). Studies suggest a higher incidence of CMV disease once prophylaxis with valganciclovir 900mg OD has been discontinued (12.1 – 24.6%), this may be due to delayed recovery of specific T cell responses. This was not observed with low dose prophylaxis, the overall incidence of CMV disease being 3%. Low dose prophylaxis is safe and efficacious, whilst facilitating asymptomatic seroconversion in high risk patients.

MoCaT as first option in the cystic echinococcosis treatment: what we have obtained
Cosmin Popa*1,2, Carmen-Michaela Cretu1, Marius Petru?escu3, Loredana Popa3, Cristian Botezatu1, Patricia Mihailescu5, Bogdan Mastalier1

1Carol Davila University of Medicine and Pharmacy, Clinic of General Surgery, “Colentina” Teaching Hospital, Bucharest, Romania, București, Romania, 2Colentina Teaching Hospital, Clinic of General Surgery, “Colentina” Teaching Hospital, Bucharest, Romania, București, Romania, 3Carol Davila University of Medicine and Pharmacy, Clinic of Parasitology, “Colentina” Teaching Hospital, Bucharest, Romania, București, Romania, 4Colentina Hospital, Clinic of General Surgery, “Colentina” Teaching Hospital, Bucharest, Romania, București, Romania, 5Ecopara Diagnostic Clinic, București, Romania

Abstract third-party references: Clinic of General Surgery, “Colentina” Teaching Hospital, Bucharest, Romania, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania

Background: According to the last recommendations of the WHO-IWGE, published since 2008 in various guidelines, the minimally invasive approach has become the first choice in treating cystic echinococcosis (CE), whenever is possible, starting with the well-known PAIR procedure. Furthermore, the other or non-PAIR percutaneous techniques gained an important place, moving from the lower position “rarely used” (but accepted) to the top: “recommended”. We prefer in our surgical clinic the MoCaT technique, developed by Prof. O. Akhan in Turkey.

Materials/methods: During 01.01.2014 – 31.05.2019, 126 patients diagnosed with CE have been admitted and treated in our surgical clinic, 88 of them being treated using minimally invasive techniques. 42 patients have had cysts considered feasible for MoCaT technique, the indications being: type CE2 and CE3b cysts, as the original technique claims, but we have used also for selected cases of type CE3a and CE4 cysts. MoCaT was performed in 40 patients, the technique failed in one case (cyst’s wall too rigid), or there was an anesthetic contraindication. 43 cysts were treated in this manner.

Results: In 10 (25%) cases the cyst’s cavity has been re-filled due to bile, lymph or mixed amount of secretion, so we needed a percutaneous drainage performed in the same way. Finally all cases have a favorable evolution; none of them would need to be treated by open surgery.

Conclusions: Using MoCaT as first option in minimally invasive treatment CE is definitely correct, but we have to choose accurately the type of CE assigned for MoCaT and to maintain the drainage as long as it is necessary. Re-filling of the cavity with bile and lymph is one way of evolution and not an error of this technique, neither an important complication; it is easily solved using a percutaneous drainage. Finally the results are optimal, obtaining the imagenistic appearance of scar.

Carbapenemase-producing Pseudomonas from Bulgarian hospitals: spread of ST233 with multiple virulence factors

Ivan Ivanov1, Veselin Dobrinov1, Krasimira Ivanova1, Elina Dobreva1, Martyn Nedjalkov1, Rumyana Hristova1, Stefana Sabtcheva1, Todor Kantardijiev1

1National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria, 2National Oncology Center - USHATO, Sofia, Bulgaria

Abstract third-party references: Supported by The Bulgarian National Science Fund under Grant No H23/H24

Background: Carbapenem-resistant Pseudomonas spp. has been classified as a highest priority concern according to WHO. MDR strains often express multiple virulence factors which pose additional problem. In this study we have characterized various MDR and XDR Pseudomonas spp. carbapenemase producers (PCP) collected over 9 year period.

Materials/methods: 178 MDR Pseudomonas spp. isolates from the collection of the National Reference Laboratory for AMR (2011-2019) were screened for carbapenemase activity by Carba NP test and antimicrobial susceptibility (AST) to 16 drugs was determined according to EUCAST. PCP were subjected to multiplex PCRs detecting 21 carbapenemase genes and associated integrons were further sequenced. Bi- and triparental mating was performed to assess transmissibility of plasmids containing bla genes. A newly devised PCR-based replicon typing scheme targeting 10 replicon types [IncP-1αβγδεζ, P-2, P-3, P-4, P-6, P-7, P-9, P-10, IncN and IncW] as well as the recently described pMOS94 and pKLC102-like plasmid families was applied for studying plasmids. MLVA9 and MLST were performed to assess clonal relatedness in P. aeruginosa. Virulence determinants (algD, aprA, fliC, toxA, lasAB, plcHN, rhlR,) were studied by PCR and biofilm formation quantified by the crystal violet assay.

Results: Overall 24 PCP (20 P. aeruginosa, 3 P. putida and 1 P. pseudoalcaligenes) were confirmed. Three blaVIM variants were identified: blaVIM-2 (n=12), blaVIM-4 (n=6), one blaVIM-5 (n=1) as well as blaNDM-1 in one isolate. All blaVIM genes were located as casettes in six different class I integrons. Interestingly none of the 21 targeted carbapenemase genes were found in four isolates. AST revealed that 22/24 isolates were XDR, resistant to ceftazidime-avibactam and ceftolozane-tazobactam and 4/24 were colistin resistant. None of the targeted replicon types were registered except the novel pMOS94-like replicon in one of the unidentified carbapenemase gene producers. Mating experiments failed suggesting chromosomal location of the carbapenemase genes. Overall six MLVA9 types were differentiated distributed in ST111, ST233 and ST235. Moderate to strong biofilm production was detected in 18/24 isolates and virulence factors (algD, plcH, toxA, rhlR) were evident in all P. aeruginosa strains.

Conclusions: XDR Pseudomonas spp. is sporadic in Bulgaria however recent tendencies suggest inter-hospital clonal spread of highly virulent blaVIM-2 ST233.

Abstract 5409

**Investigating the microbiological growth of donor organ preservation fluid in liver and kidney transplantation**

Jack Helliwell¹, Natasha Helen Cutmore*¹, Nicola Young¹

¹Leeds Teaching Hospitals Trust, Leeds, United Kingdom

**Background:** Recipient infection after organ transplantation is a major cause of morbidity and mortality. Culture of donor organ preservation fluid (PF), may be used as a surrogate of possible graft infection. However, there is currently no published UK method for its microbiological evaluation. At our centre, PF was initially sampled using blood culture bottles. This appeared to have a high isolation rate of non-pathogenic organisms.

The aim of this evaluation was to compare microbiological growth from PF using two different collection methods: blood culture bottles and universal containers. We also aimed to determine the impact of positive PF on any subsequent clinical infection post-transplantation.

**Materials/methods:** This was a tertiary hospital service evaluation in Leeds. Part 1 included all liver and kidney transplants between August 16-June 17 where PF was sampled using blood culture bottles. Part 2 included transplants between August 18-August 19. PF was sampled using universal containers and processed using a plate-based culture method.

The microbiological results of PF were evaluated to determine the isolation of recognised pathogenic and non-pathogenic organisms. Recipient data was collected including microbiological growth from all post-operative samples.

**Results:** Amongst 136 samples taken using blood culture bottles, 117 (86.0%) had positive microbiological growth, and 44 (32.4%) grew pathogenic organisms, including: *Staphylococcus aureus* (n=19), *Enterobacteriaceae* (n=11), *Enterococcus spp.* (n=5), *Pseudomonas spp.* (n=4), *Candida spp.* (n=3), *Acinetobacter spp.* (n=2) and pyogenic streptococci (n=1).

Of the 148 samples taken using universal containers, 27 (18.2%) had positive microbiological growth and 18 (12.2%) grew recognised pathogenic organisms, including: *Enterobacteriaceae* (n=7), *Candida spp.* (n=6), *S. aureus* (n=3) and *Pseudomonas spp.* (n=3).

In no cases, were the pathogenic organisms isolated in PF subsequently identified in post-operative microbiological specimens from the recipient.

**Conclusions:** Microbial growth in PF is common after liver and kidney transplantation, with a large proportion of these being due to non-pathogenic organisms. A change in sampling method from blood culture bottles to universal containers reduced isolation of non-pathogenic organisms, whilst still allowing isolation of recognised pathogens. Identification of concurrent pathogens in recipient samples did not occur, suggesting transmission via the donor organ leading to clinical infection in our population was uncommon.

Background: It has been shown that specific CD8+ T-cell response to Mycobacterium tuberculosis is higher in RC-TBI than that of remotely acquired infection. A surrogate marker for CD8+ T-cell response can be retrieved by subtracting the TB1 from TB2 interferon (IFN-γ) tube concentrations (ΔTB2-TB1). Therefore, ΔTB2-TB1 may be useful to differentiate RC-TBI from remote TBI.

Materials/methods: Retrospective, multicenter study (19 centers in 7 countries). We included individuals screened for TBI with positive QFT-plus results. Participants were grouped according to the risk for RC-TBI (high risk: contacts of pulmonary TB, and low risk: subjects with immune-mediated inflammatory diseases [IMID] before biologics, without risk factors for RC-TBI). Patients with HIV infection, advanced chronic liver or renal disease, organ transplant, or chemotherapy for cancer were excluded. We compared ΔTB2-TB1 between the two groups, and between smear-positive and smear-negative TB cases. Ethics clearance was obtained at all centers.

Results: 726 individuals were included: 405 (55.8%) TB contacts [close or frequent (74.1%), sporadic (15.3%), unknown closeness of the exposure (10.6%)], and 321 (44.2%) candidates to biologics.

</tbody>
</table>

(*1) 362 in which the closeness of the exposure was known. There were no significant differences in ΔTB2-TB1 between contacts of smear-positive and smear-negative TB cases (p=0.65). Twelve contacts had QFT-Plus conversion (IFN-γ concentration was higher in TB2 than in TB1, but only in 1 the difference was ≥0.6 UI/mL).

Conclusions: We did not find any relevant differences in ΔTB2-TB1 IFN-γ production between individuals with or without risk for RC-TBI. Our results put into question the potential role of the QFT-Plus for distinguishing recent from remote TB infection, as had previously been suggested.

Abstract 5412

**Microbial aetiology of prosthetic joint infections: what’s growing in the cultures?**
Emily Piehl*1,2, Vrishali Lopes1, Aisling Caffrey1,2,3,4, Kerry Laplante1,2,3,5

1Providence Veterans Affairs Medical Center, Rhode Island Infectious Diseases Research Program, Providence, United States, 2University of Rhode Island, College of Pharmacy, Kingston, United States, 3Providence Veterans Affairs Medical Center, Center of Innovation in Long-Term Support Services, Providence, United States, 4Brown University, School of Public Health, Providence, United States, 5Warren Alpert Medical School of Brown University, Division of Infectious Diseases, Providence, United States

**Background:** Prosthetic joint infections (P JIs) are a tremendous burden for patients and healthcare systems. The Veterans Health Administration is the largest healthcare system in the United States of America (USA), and is comprised of over 170 medical centers. The objective of this study was to describe the organisms isolated from patients diagnosed with P JIs across this national healthcare system.

**Materials/methods:** Our retrospective cohort study included patients with a diagnosis code for prosthetic joint infection between January 2016 and December 2018 who were admitted to a Veterans Affairs (VA) hospital. Cultures obtained from one day prior to admission through date of discharge were included. Cultures were only included if the site of culture could be specifically attributed to a joint and may have included more than one organism.

**Results:** We identified 692 positive joint cultures from 3,660 admissions among 2,216 unique patients. The sources of cultures were from the knee (78%), hip (17%), and other/unspecified joint site (6%). Only 7.9% (n=55) of all cultures were polymicrobial. *Staphylococcus aureus* was the most frequently identified organism (49%, n=339), followed by other staphylococci (22%, n=153), and streptococci (12%, n=83). Methicillin resistance was identified in 27% (n=92) of the *S. aureus* isolates, and the majority of methicillin-resistant *S. aureus* (76%, n=70) were isolated from the knee. Gram-negative organisms were identified in 18% (n=123) of all cultures and *Pseudomonas aeruginosa* was the most frequently implicated gram-negative organism (23%, n=28).

**Conclusions:** Prior studies have reported coagulase-negative staphylococci to be the most common pathogens in PJI, but our study found that *S. aureus* was the most frequently isolated organism in the largest healthcare system in the USA. While gram-positive pathogens are more commonly associated with PJI and are targeted in surgical prophylaxis, gram-negative organisms were present in 18% of cultures, which is concerning due to increasing virulence and antimicrobial resistance.

Antifungal prophylaxis in acute myeloid leukaemia patients receiving chemotherapy is cost-effective in a resource-limited country

Teeramet Pungprasert1, Ployploen Phikulsod2;3, Varalak Srinonprasert2;3, Dhanach Dhirachaikulpanich1;3, Narisa Tantai2;3, Satanun Maneen2;3

1Wang Nuea Hospital, Lampang, Thailand, 2Mahidol University, Tambon Salaya, Thailand, 3Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Invasive fungal infections (IFI) cause high morbidity and mortality in acute myeloblastic leukemia (AML) patients receiving chemotherapy. Antifungal prophylaxis is recommended in this setting. However, due to the healthcare reimbursement policy, this intervention is not widely implemented in resource-limited countries. We aimed to investigate the cost-effectiveness of antifungal prophylaxis in Thailand.

Materials/methods: A model estimating costs and outcomes from a hypothetical cohort of 1,000 AML patients receiving antifungal prophylaxis was established. Due to local high incidence of aspergillosis, anti-mold agents available in Thailand were included in this study; itraconazole (capsule and solution), posaconazole (solution) and voriconazole (tablet). Clinical efficacies of the antifungal drugs were obtained from a network-meta analysis study. The model accounted for the incidence rate, cost of care, healthcare resource utilization and 100-day outcomes of patients with IFI. These were based on previous local studies, a hospital registry, expert opinions, and a national healthcare price list. Results represented the extrapolated cost, life-year saved (LYs) and health outcome with quality-adjusted life-years (QALYs). The probabilistic incremental cost-effectiveness ratios (ICERs) were calculated from a provider's perspective. A one-way sensitivity analysis was also performed.

Results: Itraconazole capsule, solution, and voriconazole were dominant and cost-saving options. They resulted in LYs and QALYs gaining when compared to no prophylaxis. In a sensitivity analysis, at willingness to pay (WTP) threshold of the nation's per-capita gross domestic product per QALY gain (160,000 THB; 5291.01 USD), the probabilities that providing voriconazole would be cost-effective is highest followed by itraconazole capsule and solution. Posaconazole was also cost-effective (ICERs of 118,514 THB; 3924.31 USD/QALY gain) and gave the highest LYs and QALYs gain (0.19, 0.15).

Conclusions: Itraconazole, voriconazole, and posaconazole were all cost-effective with the itraconazole capsule being the most cost-saving. Overall, voriconazole would be considered the most cost-effective option for IFI prevention during AML treatment in this model. Antifungal prophylactic therapy, although considered expensive in Thailand, may improve clinical outcomes and reduce the economic burden of AML treatment.

Comparative evaluation of the Bruker Biotyper and Vitek MS MALDI-TOF MS systems for identification of non-albicans Candida and uncommon yeast isolates

Leyla Teke*1, Banu Bayraktar1, Ayse Baris1

1Health Science University, Sisli Etfal Training and Research Hospital, Istanbul, Turkey

Abstract third-party references: Marmara University, Department of Medical Microbiology, Becton, Dickinson and Company, Bioeksen, Terra Analysis and measurement Equipment Trade Co.Inc, bioMerieux

Background: Rapid and accurate identification of causative agent is critically important for invasive and disseminated fungal infections. The present work aims to compare two MALDI-TOF MS systems for the rapid identification of non-albicans Candida and uncommon yeast species.

Materials/methods: This study includes 157 isolates representing 23 yeast species (of 15 non-albicans). All isolates were identified by Bruker MALDI Biotyper [Bruker Daltonics], VITEK MS [bioMérieux] and BD Phoenix automated system [Becton Dickinson]. An isolate was considered correctly identified if two MALDI-TOF MS systems yielded the same results with acceptable confidence values or scores. ITS sequencing and VITEK MS Saramis database testing were performed on isolates with discordant/no identification results.

Results: Using a revised threshold of ≥1.7, Bruker MALDI Biotyper identified 155 isolates, VITEK MS IVD identified 153 isolates. Two MALDI-TOF MS systems gave 152 concordant and five discrepant results which were further clarified by ITS sequencing and VITEK MS Saramis database testing (see Table). ITS sequencing revealed that VITEK MS IVD misidentified one Meyerozyma caribbica isolate so correctly identified isolate number dropped to 152. Phoenix automated system correctly identified 128 isolates with 20 misidentifications and nine no-identification. The sensitivities of Bruker MALDI Biotyper, VITEK MS IVD and BD Phoenix in the identification of yeasts were 98.7%, 96.8%, and 81.6% respectively.

Conclusions: Both of the MALDI-TOF MS performed well in terms of rapid and accurate identification of clinical yeast isolates. Meyerozyma caribbica isolates either identified as Candida guilliermondii (closely related species) or not identified at all by MALDI-TOF MS systems. Both of MALDI-TOF MS was superior to a conventional automated identification system for identification of clinically relevant uncommon yeast species and can improve the diagnosis of infection as well as the patient management.

Abstract 5416

Susceptibility to Group A Streptococcus invasive infections in children: preliminary results of a multi-centre prospective study in France: the STREPTOPEDIA study

Jean Gaschignard1, Bidet Philippe1, Corinne Levy2, François Dubos1, Julie Toubiana4, Yves Gillet5, Emmanuel Grimpel6, Stephane Bonacorsi1, Bertrand Boisson1, Jacinta Bustamante4, Capucine Picard4, Albert Faye1

1Robert Debré University Hospital, Paris, France, 2Association Clinique et Therapeutique du Val de Marne, Creteil, France, 3Jeanne de Fandre University Hospital, Lille, France, 4Necker University Hospital, Paris, France, 5Hopital Femme Mere Enfant, Lyon, France, 6Trousseau University Hospital, Paris, France, 7Rockefeller University, New York, United States

Background: Group A Streptococcus (GAS) is associated with a broad clinical spectrum ranging from common benign to severe invasive infections (iGASI). Though iGASI can be associated with specific emm genotypes or virulence factors, the variability of disease severity in patients infected by the same strain suggests a role of host immunity. The primary objective of this study was to identify specific virulence factors and primary immunodeficiencies in children with iGASI, compared to children with non-invasive GAS infection (niGASI).

Materials/methods: A national multicenter prospective study recruited children ≤ 15 years old with iGASI in 19 hospitals between 2015 and 2018. All strains were analyzed by emm and PCR genotyping of virulence genes (speA, speB, speC, sso, sic, smeZ). They were compared to strains isolated in matched children for age and period diagnosed with niGASI in a pediatric outpatient network. An immunological work-up was performed in children with iGASI (WBC count with blood smear, lymphocyte phenotyping, plasma Ig dosage, vaccinal serologies, complement analysis and abdominal ultrasound) and whole exome sequencing (WES) in those with no risk factor.

Results: We included 107 children hospitalized for iGASI, of which 70 had a risk factor for iGASI (mainly chickenpox or immunosuppression). Toxic shock or severe sepsis were more common in children without risk factor compare to children with risk factor [21/67 vs 3/33, p=0.01] whereas age and sex ratio were similar. Emm1 was more frequent in iGASI (38 vs 12%) and emm89 in niGASI (22 vs 7%). SpeA was more frequently found in iGASI than niGASI strains (47 vs 18%). Among strains of iGASI, the diversity of emm genotypes measured by the Shannon index was significantly greater in the group with no risk factor [2.22 vs 1.66, p=0.009]. So far, a primary immunodeficiency has been identified in two patients (one asplenia, one GATA2 mutation).

Conclusions: The greater diversity of emm genotypes in children with risk factor-free iGASI may suggest host involvement. WES of children with no risk factor along with genome sequencing of their GAS strain are ongoing to further characterize the association between bacterial virulence and host immunity in iGASI.

Abstract 5417

Healthcare-associated Staphylococcus aureus bloodstream infection (HA-SABSI): clinical practice variation in its management

Mercedes García-Gasalla*, Carmen Collado Giner1, Aroa Villoslada Gelabert1, Lola Ventayol-Aguiló1, Mari Cruz Perez-Seco1, María Arrizabalaga Asenjo1, María Carmen Gallegos Alvarez1

1Hospital Universitario Son Llàtzer, Palma de Mallorca, Spain

Background: Previous studies assessing physician practices in the management of SABSI have shown there is considerable practice variation.

Materials/methods: Retrospective study of HA-SABSI diagnosed from 01/08/2015 to 31/07/2019 in Son LLàtzer Hospital, a 350-bed university hospital in Majorca (Spain). Epidemiological, clinical and microbiological data, treatment prescribed, and outcomes were collected and analysed.

Results: After excluding patients who were transferred while on therapy and those who died before microbiological results were obtained, 82 patients were included. Median age was 73y [0-93] and mean Charlson comorbidity index was 5.9 [SD: 3.1]. SABSI was associated with peripheral venous catheters (n=36), central venous catheters (CVC) (n=11), port or tunnelled CVCs (n=12), and unknown sources/other foci (n=24). Repeated blood cultures (BCs), transthoracic, and transoesophageal echocardiographies were performed in 60 (73.2%), 53 (64.6%), and 16 (19.5%) patients, respectively. Complicated SABSI (c-SABSI) were observed in 30 (36.6%) patients and infectious endocarditis diagnosed in 11 (13.4%). MRSA was isolated in 19 (23.2%) cases. Patients with MRSA-HA-BSI were hospitalised in the Intensive Care Unit more frequently than patients with MSSA-HA-BSI (5/19 versus 5/63, p≤0.005), and 8 had complicated BSIs. MRSA-HA-BSI was treated with: vancomycin in 4 (21.1%) cases, linezolid in 5 (26.3%), and daptomycin alone or in combination in 9 (47.4%). MSSA-HA-BSI was treated with: cloxacillin in 34 (54%) cases, daptomycin alone or in combination in 14 (22.3%), linezolid in 5 (7.9%), vancomycin in 4 (9.5%), and other antibiotics in 4 (6.3%). Vancomycin MIC was >1 μg/mL in 6 cases (Etest®). Mean duration of antibiotic therapy was 13.8 days [SD: 5.6] for uncomplicated SABSIs and 21.1 days [SD: 7.1] for c-SABSI [p≤0.05]. With regard to outcomes, 2 patients were readmitted due to persistent BSI and 24 patients died. Death was related to c-SABSI in 8/30 of the cases versus 5/52 for uncomplicated SABSI [p≤0.05] and to MRSA-BSI in 2/19 of the cases versus 11/63 for MSSA-BSI [p=ns].

Conclusions: Adherence to guidelines on HA-SABSI management is poor, especially for the performance of repeated BCs, echocardiographies, and selection and duration of antibiotic therapy in complicated BSIs. The high mortality observed in complicated MSSA-HA-BSI may be related to these factors.

Abstract 5418

**Novel lipid A mimetics (BECC438 and BECC470) act as potent adjuvants in bacterial and viral subunit vaccines**

Erin Harberts¹, David Varisco¹, Akshay Jain², Charles Middaugh², Robert Ernst*¹

¹University of Maryland - Baltimore, Baltimore, United States, ²University of Kansas, Lawrence, United States

**Background:** Infectious diseases continue to be the leading cause of morbidity and mortality worldwide, and therefore, an urgent need exists to develop effective vaccines against a variety of pathogens. Effective vaccines contain appropriate antigens from the vaccine target and adjuvant(s) to potentiate the magnitude, duration and nature (humoral and/or cellular) of the generated immune response. Bacterial enzyme combinatorial chemistry (BECC) was developed to create bacterial lipid A that are partial agonists for innate immune receptor Toll-like receptor 4 (TLR4). Specifically, BECC allows for the synthesis and characterization of custom lipid A structures, the lipid anchor of lipopolysaccharide. These defined modifications have the potential to control the quality of specific activating immunity while avoiding excessive adverse host reactions. BECC is used to establish a robust mechanism for adjuvant/vaccine design.

**Materials/methods:** From initial screenings, two lead adjuvant candidates were identified, BECC438 and BECC470 that were subsequently formulated with bacteria and viral antigens, including *Yersinia pestis* (rF1-V), *Staphylococcus* alpha toxin, and human papillomavirus (VLPs). Mice were immunized using a two-week interval prime-boost-boost, prime-boost, or prime alone vaccination strategy with several different formulations. Antigen-specific antibody titers were measured by ELISA for total IgG, IgG1, and IgG2c(2a) isotypes and levels of efficacy/survival were determined using murine pathogen challenge models. Subsequently, vaccination with ovalbumin was used to further characterize the longevity of the adjuvant-driven immune responses.

**Results:** Vaccine formulation adjuvanted with BECC438 or BECC470 result in durable and IgG1/IgG2c(2a) balanced antibody production, as compared to alhydrogel or the TLR4 agonist PHAD, for all antigens tested. For all antigens, both BECC compounds allowed for durable antibody production, antigen sparing, dose sparing, adjuvant sparing, production of T follicular helper cells, and interestingly provided protection against a heterologous challenge in viral infection models.

**Conclusions:** Adjuvants play a critical role in enhancing and directing adaptative immune responses to vaccine antigens. Our data demonstrate that the BECC molecules induce strong T₁,1 and T₁,2 immune responses and so will be effective adjuvants in vaccines using purified protein, peptide, and DNA antigens. Data presented provide evidence that BECC molecules will be effective as a component in next-generation vaccine formulations.

Clinical epidemiology of Lyme disease in Quebec, Canada and compliance with American and European guidelines
Jean Berchmans Musonera*, François Milord1,2, Louis Valiquette3,4, Geneviève Baron1,2, Dominique Marcoux1, Karine Thivierge5, Claire Nour Abou Chakra1, Samuel Bedard-Dallaire1, Raphaël Lachance7, Jeremy Bourget7, Catherine Simard1, Emmanuelle Cantin2, Farhad Abbasi7, Louis-Patrick Haraoui9, Alex Carignan1,4

1Université de Sherbrooke, Faculté de médecine et des Sciences de la santé, Département de microbiologie et infectiologie, Sherbrooke, Canada, 2Université de Sherbrooke, Faculté de médecine et des sciences de la santé, Département des sciences de la santé communautaire, Sherbrooke, Canada, 3CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada, 4CRCHUS CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada, 5CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada, 6Laboratoire de santé publique du Québec, Montréal, Canada, 7Université de Sherbrooke, Faculté de médecine et des Sciences de la santé, Sherbrooke, Canada, 8Université Laval, Québec, Canada, 9Faculté de médecine et des Sciences de la santé, Département de microbiologie et d’infectiologie, Sherbrooke, Canada

Background: Little is currently known about the management and clinical evolution of patients with Lyme disease (LD) in Canada. This study aimed to describe the management of LD in Quebec, Canada, and assess compliance to the Infectious Disease Society of America and European guidelines.

Materials/methods: We conducted a retrospective multicenter cohort study of patients with serologically confirmed LD seen in acute care facilities in two endemic regions of Quebec from 2004 to 2017. Our main outcome was a favourable clinical evolution, defined as the resolution of all clinical signs, 3 months following initiation of a LD treatment. Two clinicians assessed clinical evolution and guidelines adherence independently.

Results: Over the study period, 614 serologically confirmed LD cases were identified through the provincial laboratory database. Medical charts for 272 patients from 14 institutions were available and complete for data collection. The median age of patients was 51 years [interquartile range (IQR) 32-64]. Infection led to hospitalization of 48 patients (17.7%) for a median duration of 4 days [IQR 1-4]. Early localized LD was recorded in 33% of cases [90/272], early disseminated LD in 52% [140/272] and late disseminated LD in 15% of patients [42/272]. A favourable outcome was observed in 266/270 (98.5%) patients for whom follow-up visits were documented, while 10% of patients (28/270) developed a Post-Lyme Disease Syndrome. One death unrelated to LD occurred 589 days after diagnosis. Compliance to IDSA guidelines was observed in 219/243 (90.1%) patients for whom data on antimicrobial therapy was complete, and did not vary throughout time [2004-2013: 54/60 (90%); 2014-2015: 61/68 (90%); 2016-2017: 104/115 (90.4%); p=0.99]. The main reason for noncompliance was a duration of therapy superior to recommendations [14/24, 59.3%]. Compliance to the 2018 National Institute for Health and Care Excellence [NICE] guidelines was lower [110/243, 45.2%], mainly because of a duration of therapy superior to recommendations [73/133, 54.9%; p<0.001].

Conclusions: Most patients had complete resolution of the objective clinical signs at three months following the initiation of treatment. We did not observe changes in the compliance to IDSA guidelines over 13 years. This study also emphasizes significant differences between European and American guidelines.

Early microbiome changes associated with the novel, targeted-spectrum antibiotic ACX-362E compared to oral vancomycin

Kevin Garey1, Khurshida Begum1, Chris Lancaster1, Anne Gonzales-Luna1, Dinh Bui1, Ming Hu1, Michael Silverman2, M. Jahangir Alam1

1University of Houston, Houston, United States, 2Acurx Pharmaceuticals, White Plains, United States

Background: The mechanism by which a healthy microbiome loses colonization resistance, leading to gut colonization with Clostridioides difficile and multidrug-resistant organisms after antibiotic use is poorly understood. Oral vancomycin has broad-spectrum activity against all major phyla of the human gut microbiome including Firmicutes, Bacteroidetes, and Actinobacteria. ACX-362E is a DNA polymerase IIIC inhibitor in development for the treatment of C. difficile infections that specifically targets low G+C Gram positive bacteria, including some Firmicutes. The purpose of this study was to compare early microbiome changes associated with use of these antibiotics in healthy volunteers.

Materials/methods: As part of the completed phase I clinical study of ACX-362E, stool samples were collected daily from volunteers given a ten-day course of ACX-362E (300 or 450 mg given twice daily) or vancomycin (125 mg given four times daily). DNA was extracted from stool and sequenced using shotgun metagenomics (Illumina HiSeq). Daily antibiotic concentrations were measured by LC-MS/MS. Phylum- and family-level changes in microbiota were compared from baseline.

Results: Eighteen subjects (female: 33%) aged 30±8 years were enrolled. Baseline microbiota were similar between study groups and comprised of Firmicutes (62%), Actinobacteria (23%), and Bacteroidetes (11%). Concentrations of all antibiotics exceeded 2,000 ug/g of stool by day 5 of therapy. In subjects given vancomycin, host microbiota had been replaced by two distinct families, Lactobacillaceae or Enterobacteriaceae, by day 10 of dosing. At day 10, subjects given either dose of ACX-362E had replacement of Firmicutes by an expansion of existing baseline Actinobacteria microbiota, primarily Bifidobacteriaceae.

Conclusions: Early microbiome changes after antibiotic therapy were associated with the pharmacologic activity of the antibiotic. A targeted-spectrum agent ACX-362E was associated with replenishment of host microbiota while a more-broad spectrum antibiotic led to replacement with novel microbiota.

**Abstract 5421**

**Vancomycin for patients with MRSA bloodstream infections (BSIs) is nephrotoxic even within the recommended area under the curve (AUC) therapeutic exposure range**

Thomas Lodise*, Marc Scheetz2, Joseph Carreno1, Thomas Holland3

1Albany College of Pharmacy and Health Sciences, Albany, United States, 2Midwestern University Chicago College of Pharmacy, Chicago, Illinois, United States, 3Duke University Medical Center, Durham, North Carolina, United States

**Abstract third-party references:** Marmara University, Department of Medical Microbiology, Becton, Dickinson and Company, Bioeksen, Terra Analysis and measurement Equipment Trade Co.Inc, bioMerieux

**Background:** Vancomycin remains the standard of care for serious MRSA infections, but optimal dosing is constrained by a tradeoff between clinical effectiveness and acute kidney injury (AKI) at higher vancomycin exposures. Draft consensus vancomycin dosing guidelines recommend targeting a daily AUC of 400 to 600 mg-h/L to minimize AKI while preserving effectiveness. To investigate AKI risk within this range, we evaluated the relationship between day 2 AUC and change in serum creatinine (SCr) from baseline among patients who were enrolled in PROVIDE, a multicenter prospective cohort study of patients with MRSA BSIs who received vancomycin [PMID: 31157370].

**Materials/methods:** Data from previously completed prospective, multi-center (n=14), observational study (2014-2106) of hospitalized adults with confirmed MRSA BSI treated with VAN ≥ 72 hours who had a Scr ≤ 2 mg/dL were analyzed. Vancomycin day 2 AUC were estimated using maximum a posteriori Bayesian procedure in ADAPT 5 (Bayesian Estimator). Maximum change in SCr was calculated by subtracting the maximum recorded SCr value during vancomycin therapy from baseline SCr value. Univariable negative log binomial generalized linear regression (NLBGLR) was used to assess the relationship between Day 2 vancomycin AUC and change in SCr. Multivariable NLBGLR was performed and included covariates which had previously demonstrated associations with AKI. All analyses were performed with SAS version 9.4.

**Results:** Of the 265 patients in PROVIDE, 212 had a Scr < 2 mg/dL. Mean (SD) baseline SCr was 1.0 (0.4), mean (SD) age was 60 (18), mean (SD) APACHE II score was 11 (5); 124 (58.5%) subjects were male. In the univariate NLBGLR analysis, the mean change in SCr from baseline increased as a function of the day 2 AUC (figure). In the multivariable regression analysis, each 100 incremental increase in was associated with a 9% increase in the mean SCr change after adjusting for clinically relevant covariates.

**Conclusions:** Among patients with MRSA BSIs, SCr increased as a function of the day 2 vancomycin, even with vancomycin exposures that is within the recommended AUC therapeutic range of 400-600.

Abstract 5423

**Botulism early recovery: one-decade experience in a referral centre**

Firouze Hatami¹, Ilad Alavidarazam*¹², Shervin Shokouhi¹, Masoud Mardani Dashti³

¹Shahid Beheshti of Medical Sciences, Tehran, Iran, ²Clinical Research Development Center, Loghman Hakim Hospital Shahid Beheshti University of Medical Sciences, Tehran, Iran

**Background:** Botulism is a rare and fatal disease that has various forms that food-borne botulism is often identified as an outbreak. About 1000 cases of foodborne botulism are reported annually worldwide. We reviewed all clinical features, lab data and outcome of patients who have referred to our tertiary center.

**Materials/methods:** All cases of proven botulism at an academic referral center and teaching hospital were retrospectively reviewed between 2009-2019.

**Results:** During 10 years, 53 cases of clinical or laboratory confirmed botulism (mean age 36.6 (14-74) and 56.6% males/43.4% females) were extracted. In seven cases, source of botulism was unclear and in 2 patients systemic symptoms were occurred after iatrogenic injection of botulinum toxin. The most of cases (83%) had an obvious food source, including conserved foods, tuna fish and corn (the most prevalent), 28.3% homemade dairy products, 5.7% red meat, 5.7% sausage and 1.9% salty fish.

In 66% of patients initial symptoms were presented in less than 36 hours and in 20.8% of them ≥36 hours; in 7 indeterminate source, the onset time could not be estimated. All patients had cranial involvement, including 66% ptosis, 75.5% diplopia, 71.7% dysphagia, 43.3% dysarthria, 49.1% impaired gag reflex and 28.3% mydriasis. About 47.2% of patients had autonomic manifestations [dizziness, constipation, dry mucosa, etc.] and 49.1% had gastrointestinal symptoms [abdominal pain, nausea, vomiting, etc.]. Some patients had diarrhea due to other concomitant cause of food poisoning.

Except for two patients who were unable to be prescribed due to immediate drug reaction, the rest were treated with trivalent antitoxin (A, B, E) according to our center protocol. About 17% of patients were intubated due to impaired intercostal muscle tone. Eventually, two patients died due to massive embolism and cardiac asystole. Surprisingly, in 50.9% of patients complete resolution of symptoms were documented.

**Conclusions:** Early treatment in most cases resulted in a favorable clinical outcome. Although the duration of complete resolution of symptoms usually last for several weeks and is dependent to half-life of regeneration of neural synapses, in our experience, most of patients revealed at least partial relief in early phase after treatment.

**Epidemiology of pyrazinamide-resistant tuberculosis in a low-incidence setting**

Carmen Martín Higuera*, Elisabeth Prieto Ávalos, Beatriz Velazquez-Gonzalez, María Jesús Ramírez-Vela, Irene Muñoz Gallego, Paula Lopez-Roa

1Hospital Universitario 12 de Octubre, Madrid, Spain

**Background:** Pyrazinamide (PZA) is a central component of first-line and second-line regimens for treatment of both susceptible and multidrug-resistant (MDR) tuberculosis (TB). Spain is a low-incidence TB country with an increase burden of MDR TB cases but little is known regarding the prevalence of PZA monoresistance, and PZA resistance in drug susceptible as well as MDR-TB isolates. We aimed to investigate the prevalence of PZA mono-resistance and PZA resistance among susceptible and MDR-TB isolates.

**Materials/methods:** we carried out a search of all isolates reported as PZA resistant in a tertiary referral hospital in Madrid, Spain, between 2016 and 2019. PZA susceptibility testing of these isolates was performed by using the automated BACTEC MGIT 960 system. Isolates with an initial result of PZA resistance were sent to the national reference laboratory for repeat susceptibility testing and for pncA sequencing.

**Results:** During the study period a total of 256 culture-positive TB cases were reported in our hospital. Of these, we identified 15 PZA resistant strains (5.9%). 11/15 were PZA-monoresistant and 4/15 were PZA-resistant MDR cases. Of the 11 PZA-monoresistant isolates, 9 were identified as *M. bovis* and 1 was identified as *M. bovis* BCG. The remaining isolate was identified as PZA-monoresistant *M. tuberculosis*. Among the 15 PZA-resistant strains, 3 different mutations were detected; C169G (H57D), A29G (Q10B), and A422C (Q141P). C169G (H57D) was only detected in *M. bovis* species. The remaining two mutations were found in MDR strains. No mutation was detected in the PZA-monoresistant *M. tuberculosis* isolate.

**Conclusions:** This study demonstrates that, in our setting, PZA monoresistance is a reliable marker of *M. bovis* species since only one isolate of *M. tuberculosis* was identified as PZA-monoresistant. Consistent with that reported in the literature, PZA resistance was mostly detected in MDR strains.

Nanoparticles loaded with extracts of Brucella abortus vaccine (strain RB51) trigger protective immune responses in murine macrophages and splenocytes

Africa Cubero Ribas1, Gabriel Alberto March Rosselló2, María Purificación Gutiérrez1, Dino Joaquin Gobelli3, Carlos Durantez4, Miguel Angel De La Fuente2, María Simarro1, Antonio Orduna Domingo*1,2

1Facultad de Medicina, University of Valladolid, Valladolid, Spain, 2Hospital Clínico Universitario de Valladolid, Valladolid, Spain, 3Institute of Molecular Biology and Genetics IBGM, University of Valladolid, Valladolid, Spain, 4University of Castilla-La Mancha Toledo Campus, Toledo, Spain

Background: Brucella sp. is a facultative intracellular pathogen able to survive within macrophages by inhibiting phagolysosome fusion and perturbing the early immune response to infection. This in vitro study evaluated the protective effect of hydrogel nanoparticles (NP) containing Brucella abortus vaccine (strain RB51) in murine macrophages and splenocytes.

Materials/methods: The protein extracts were obtained by the hot water extraction method and characterized by LC-MS/MS prior to its encapsulation by supercritical anti-solvent method. Peritoneal macrophages and splenocytes were obtained from 8-12 weeks old C57BL/6 mice. Macrophages were seeded at 5x105 /well in 24-well plates. Splenocytes were seeded at a density of 4x106/ml in 6 well plates. Cells were cultured in the presence of NP [20 µg/mL protein equivalent] and collected at different time points [6 hours, 1, 2 and 3 days]. Total RNA was extracted and reverse-transcribed to generate cDNA for SYBR-Green based qPCR analysis of the following genes: IL-2, IL-4, IL-6, IL-10, IL-12a, IL-17a, IL-23a, IFN-gamma, TNF-alpha and Tgfb1. 18S and beta-actin genes were used for the normalization of the qPCR data.

Results: Macrophages: NP strongly induced the upregulation of IL-6, TNF-alpha and IL-12a mRNAs [1777, 104 and 373 fold increase, respectively] after 6 hour incubation, and also led to a mild upregulation of IL-23a mRNA [20 fold increase] and very slight upregulation of IL-10 [4 fold increase]. Upregulation of these transcripts peaked at 6 hours. Splenocytes: NP induced the expression of IL-2, IFN-gamma and IL-17 transcripts gradually increased up to a maximum level on day 3 [8.6, 13.1 and 25.7 fold increase, respectively]. The levels of mRNA for Th2 cytokine IL-4 remained unaltered.

Conclusions: NP were able to trigger a pro-Th1 response (IL-12a, p<0.001), pro-Th17 response (IL-23a, p<0.001) and pro-inflammatory response (IL-6, p<0.001) in mouse macrophages, and a Th1 response (IL-2 and IFN-γ, p<0.001) and a Th17 response in mouse splenocytes. Both Th1 and Th17 responses are key to the elimination of Brucella sp.

Abstract 5426

**Prospective observational study of antimicrobial stewardship programmes in Brazil: preliminary results**

Rochele Menezes¹, Mara Gonçalves², Magda Costa², Eliane Krummenauer¹, Cézane Reuter³, Jane Dagmar Renner³, Marcelo Carneiro¹,⁴

¹Hospital Infection Control Service - HSC and Stricto Sensu Health Promotion Program, University of Santa Cruz do Sul, Santa Cruz do Sul, Brazil, ²National Agency for Sanitary Surveillance, ANVISA, Brasília, Brazil, ³Stricto Sensu Health Promotion Program, University of Santa Cruz do Sul, Santa Cruz do Sul, Brazil, ⁴Brazilian Association of Hospital Infection Control and Epidemiology Professionals, São Paulo, Brazil

**Background:** The worldwide trend of the clinical management of antimicrobial use through the Antimicrobial Stewardship Program (ASP) aims to rationalize therapy. The need to diagnose the Brazilian national scenario is essential to define strategies due to regional differences and standardize governmental norms. In this context, the lack of national hospital data contributed to the study performance.

**Materials/methods:** This is a national, cross-sectional prospective study, containing preliminary data from 954 (56.0%) hospitals with Adult Intensive Care Unit (ICU), corresponding to 25,565 beds, from all 27 Brazilian states, including the variables that contributed and favored the implementation of ASP. Data collection was carried out from July to August 2019.

**Results:** Of the 954 hospitals, 453 (47.5%) declared that they had the ASP implemented and among the most frequent factors that contributed to the program were: 369 (81.5%) had support from the hospital’s senior management; 343 (75.7%) had availability of clinical protocols based on the institutional profile; 276 (60.9%) had support and adherence from prescribing physicians and 259 (57.2%) had the official definition of a multiprofessional group (managing team) responsible for the creation of the ASP. Among the main reasons that delayed the implementation were: 202 (44.6%) components of the operational team had not defined or enough time to perform the ASP activities; 134 (29.6%) lack of information technology support; 173 (38.2%) met resistance or opposition from the hospital prescribing physicians and 116 (25.6%) lacked commitment of the hospital teams to implement the ASP norms.

**Conclusions:** ASP is a viable strategy for the optimization and rational use of antimicrobials in developing countries. In Brazil, this plan is still under development, but will contribute to objective actions in the ICUs led by the government, with an important impact on the sustainability of antimicrobial resistance dissemination control in the country.

**Presenter email address:** rochelemenezes@unisc.br
Background: Diabetes Mellitus (DM) increases the risk of developing Tuberculosis (TB) infection up to 3 times and causes unfavorable treatment outcomes. It has been described that the association between DM/TB reaches 15.3% worldwide and in Latin America it can be 7.7%. This work described the clinical presentation and the outcomes to treatment of patients with a history of DM and active TB infection treated in a health institution in Cali, Colombia between 2011-2018.

Materials/methods: a cases series of patients with diagnosis of TB and history of DM reported in the institutional registry of Mycobacteria at University Hospital Fundación Valle del Lili, Colombia, between 2011 and 2018 were described. The exploratory analysis of data for evaluation of outliers and lost data was carried out. Categorical variables were summarized in tables of absolute and relative frequencies; the quantitative variables were reported according to their distribution using measures of central tendency and dispersion.

Results: Of the 1097 records of patients examined during the study period, 69 were found with a history of DM and TB infection (6.2%); the majority of patients were men (54%), of mixed-race (61%) with a median age of 63 years old (Interquartile Range - RIC: 55-77 years old); smoking was the most outstanding antecedent (27%). The pulmonary location of the infection was the most frequent presentation (72%); Fever (61%), weight loss (58%) and cough (55%) were the most commons symptoms. In 81% of the patients, microbiological confirmation was achieved, mostly by smear microscopy (53.6%). 70% of the subjects with known outcomes met the cure criteria, 13% failed and 10.14% died.

Conclusions: we recommend to develop models of differential integral health care in diabetics patients, to assess the risk of developing TB, since almost a quarter of the diabetic population may have unfavorable treatment outcomes.

Presenter email address: jofergarcia@gmail.com
Abstract 5432

**Evaluation of the performance of the Dynamiker Fungus (1-3)-β-D-glucan assay for the diagnosis of invasive aspergillosis in high-risk patients with haematological malignancies**

Maria Siopi1*, Maruša Krmelj1, Stamatis Karakatsanis2, Christoforos Roumpakis3, Elina Eldeik4, Konstantinos Korantanis5, Helen Sambatakou1, Panagiotis Tsirigotis1, Maria Pagoni2, Nikolaos Syspas5, Spyros Pournaras1, Joseph Meletiadis1;6

1Clinical Microbiology Laboratory, “Attikon” University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 2Department of Hematology and Lymphoma, Unit of Bone Marrow Transplantation, “Evangelismos” General Hospital, Athens, Greece, 32nd Department of Internal Medicine, Hematology Unit, “Attikon” University General Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece, 42nd Department of Internal Medicine, “Hippokration” General Hospital, Athens, Greece, 5Pathophysiology Department, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 6Department of Medical Microbiology and Infectious Diseases, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** Non-culture-based methods, like detection of circulating galactomannan (GM) and (1-3)-β-D-glucan (BDG), are important adjunctive diagnostic tools for invasive aspergillosis (IA). Until recently, only the Fungitell® assay (Associates of Cape Cod) has been commercially available (CE marking and FDA approval) for BDG testing. This changed with the release of the Dynamiker® Fungus BDG assay (CE marking), which contains detachable microplate rows allowing the test to be performed on a few clinical samples. We therefore evaluated the performance of the Dynamiker® Fungus assay in serum of high-risk haematological patients for the diagnosis of IA providing comparative data with the Fungitell® assay.

**Materials/methods:** During 4/2013-7/2015, a total of 173 serial blood specimens from 62 patients with haematological malignancies (35 AML, 9 ALL, 2 MDS, 2 NHL, 14 other) were collected twice-weekly and tested for GM (Platelia Aspergillus EIA) and BDG (Fungitell®/Dynamiker®). 19/62 (31%) patients had probable IA and received voriconazole, while 43 had no IA according to the EORTC/MSG criteria. The BDG assays were performed following the manufacturer’s instructions and the samples were considered positive, indeterminate/inconclusive or negative based on the BDG levels of <60, 60-79, ≥80 pg/mL (Fungitell®) and <70, 70-95, >95 pg/mL (Dynamiker®), respectively. The BDG values generated by the two assays were compared quantitatively (Spearman analysis) and qualitatively (3x3 x² analysis). Sensitivity/specificity rates and positive/negative predictive values (PPV/NPV) were calculated for each BDG assay.

**Results:** The mean absolute and relative difference between the BDG values of the assays tested was 50 pg/mL and 14%, respectively. BDG concentrations generated by the two assays were linearly correlated (slope 0.65±0.03, r²=0.73) with high degree of correlation [Spearman r (95%CI)=0.91 (0.88-0.94), p<0.0001]. Sensitivity, specificity, PPV and NPV was 73%, 50%, 23%, 90% for Fungitell® and 68%, 63%, 28%, 91% for Dynamiker®, respectively. Statistically significant correlation was found between the assays [χ²(4)=121.7, p<0.0001] with 85% agreement and 6% major discrepancies [Fungitell® negative/positive → Dynamiker® positive/negative and vice versa].

**Conclusions:** The Dynamiker® Fungus BDG assay is a useful complementary test for diagnosing IA, with technical flexibility to assist laboratories that process a small number of samples.

Abstract 5433

Performance of VITEK 2 AST-GN meropenem/vaborbactam for antimicrobial susceptibility testing of Enterobacteriaceae and Pseudomonas aeruginosa: a multi-centre study

Simone Franklin*, Hari Dwivedi1, Gary Procop2, Maria Traczewski3, Omai Garner4, Parampal Deol1

1bioMérieux Inc., St. Louis, MO, United States, 2Cleveland Clinic Foundation, Cleveland, OH, United States, 3Clinical Microbiology Institute, Portland, OR, United States, 4University of California Los Angeles (UCLA), Los Angeles, CA, United States

Background: Meropenem/Vaborbactam (MEV), a β-lactam combination antimicrobial consisting of meropenem, a carbapenem, and vaborbactam, a beta-lactamase inhibitor, is indicated for treatment of patients 18 years and older with complicated urinary tract infections (cUTI) including pyelonephritis caused by designated susceptible bacteria. In this study, the performance of VITEK® 2 AST-GN MEV with Enterobacteriaceae and Pseudomonas aeruginosa was evaluated against the CLSI broth microdilution (BMD) reference method.

Materials/methods: A total of 526 clinical and challenge isolates, including 449 Enterobacteriaceae and 77 Pseudomonas aeruginosa were tested by VITEK® 2 AST-GN MEV and BMD reference at four clinical trial sites. Results were analyzed for essential agreement (EA), category agreement (CA), major error (ME) and very major error (VME) rates following the ISO performance criteria and (EA and CA ≥90%, ME and VME ≤3.0%) and using EUCAST breakpoints for Enterobacteriaceae and Pseudomonas aeruginosa (S ≤ 8µg/mL, I = N/A, R ≥ 16µg/mL).

Results: VITEK® 2 AST-GN MEV clinical trial performance is summarized below for Enterobacteriaceae and Pseudomonas aeruginosa. VITEK® 2 AST-GN MEV met the ISO susceptibility performance criteria for EA, CA, ME and VME, when applying EUCAST breakpoints.

<table>
<thead>
<tr>
<th>Claimed Species</th>

The importance of CXCL13 cytokine as a biomarker in the molecular diagnosis of Lyme neuroborreliosis versus multiple sclerosis

Teresa Carreira*, Filipa Geraldo Dias, Ana Armada, Maria Luísa Vieira

1Universidade NOVA de Lisboa, Global Health and Tropical Medicine (GHTM), Institute of Hygiene and Tropical Medicine (IHMT), Lisbon, Portugal, 2Universidade NOVA de Lisboa (UNL), Institute of Hygiene and Tropical Medicine (IHMT), Lisboa, Portugal, 3Universidade NOVA de Lisboa, Lisbon, Portugal, Global Health Tropical Medicine (GHTM), Institute of Hygiene and Tropical Medicine (IHMT), Lisbon, Portugal

Abstract third-party references: Leptospirosis and Lyme Borreliosis laboratory, Medical Microbiology Unit, Tropical Medicine Global Health and Tropical Medicine (GHTM), Institute of Hygiene and Tropical Medicine (IHMT), Universidade NOVA de Lisboa (UNL), Lisbon, Portugal

Background: Lyme Borreliosis (LB) is a multisystemic disease caused by spirochetes, belonging to the *Borrelia burgdorferi* sensu lato complex, which includes different pathogenic species. The transmission of these spirochetes occurs by ixodid ticks bite. In Portugal, LB is often under-diagnosed due to the clinical polymorphism. Diagnosis is mostly clinical and epidemiological. When untreated, the disease can progress to Lyme Neuroborreliosis (LNB). Sometimes it is difficult for the laboratory to help the clinician in the diagnosis of this disease. Thus, it is crucial to develop/testing methods that support a more efficient diagnosis. The goal of this work was to understand the role of CXCL13 as a biomarker for diagnosis of LNB vs. Multiple Sclerosis (MS) in cerebrospinal fluid (CSF) samples from patients suspected or diagnosed of LB since it is known that human-specific cells (monocytes, macrophages, and dendritic cells) produce this cytokine.

Materials/methods: CSF samples (N=327) were used, and the concentration of the CXCL13 in CSF (cut-off 30pg/ml) was determined using an ELISA assay. For detection of anti-*B. burgdorferi* s.l., antibodies, and amplification of its DNA, the samples were analyzed by immunofluorescence (IFA) and nested-PCR [intergenic space 23S (rrl)-5S (rrf) and flaB gene], respectively.

Results: The CXCL13 cytokine was quantified in 88/327 samples [6/88, corresponding to LNB patients (>250pg/ml) and 82/88 to probable cases (>30pg/ml) if neurological symptoms were present], and in 24/327 the results were borderline (20-30pg/ml). Samples with high concentrations of CXCL13 were associated with LNB, or MS. IFA results showed (5+/197) and six borderline samples. The evaluation by nested-PCR targeting flaB gene and intergenic space, showed (2+/125) and (9+/323), *Borrelia* DNA detection, respectively. Overall, the results of the various laboratory approaches showed the presence of anti-*B. burgdorferi* antibodies in 6% (11/197), while the test under study quantified the CXCL13 cytokine by 34% (112/327) of the total CSF samples. On the other hand, *Borrelia* DNA detection was only 2-3%.

Conclusions: This cytokine proved to be an important and promising biological marker for late LB, supporting namely the diagnosis of LNB vs. MS, as well as distinguishing several diseases from Central Nervous System (CNS).

Clinical features related to \textit{blaKPC} versus \textit{blaNDM} carbapenem-resistant \textit{Enterobacteriaceae} bacteraemia: are we talking about the same?

Patricio Favier*, Enrique Serio1, Jesica Maresca1, Claudia Muñoz Soto1, Fidel Pinilla Huayta2, Carla Raffo1, Liliana Kumar1, Johanna Perez1, María Antonia Lovigne1, Ivana Primost2, Carlos Blanco1, Diego Torres1, Alejandra Marcela Macchi2

1Hospital de Trauma y Emergencias Dr. Federico Abete, Servicio de Infectología, Pablo Nogués, Argentina, 2Hospital de Trauma y Emergencias Dr. Federico Abete, Servicio de Terapia Intensiva, Pablo Nogués, Argentina, 3Hospital de Trauma y Emergencias Dr. Federico Abete, Laboratorio de Microbiología, Pablo Nogués, Argentina, 4Hospital de Trauma y Emergencias Dr. Federico Abete, Laboratorio de Genética y Biología Molecular, Pablo Nogués, Argentina, 5Municipalidad de Malvinas Argentinas, Secretaría de Salud, Pablo Nogués, Argentina

\textbf{Background}: Carbapenem-resistant Enterobacteriaceae (CRE) infections are a significant public health issue. CRE-\textit{blaKPC} events are predominant, even though other CRE infections (e.g.: CRE-\textit{blaNDM}) are arising in several countries. Hence, understanding their particular clinical features could be an important tool for their proper management. Our aim was to compare clinical characteristics between CRE-\textit{blaKPC} vs. CRE-\textit{blaNDM} bacteraemia. The secondary objective was to contrast 14-day mortality.

\textbf{Materials/methods}: Retrospective and observational study which included patients with CRE-\textit{blaKPC} or CRE-\textit{blaNDM} bacteraemia from a tertiary hospital of Buenos Aires Province (Argentina) from January 2016 to September 2019. Consecutive episodes were matched 1:1 by each mentioned CRE. Patients who died before 48h of bacteremia onset and those who did not receive empiric therapy were excluded. Any antimicrobial combination with at least one active drug or scheme based on time-killed curve were taken into account for the analysis. Cultures and susceptibility tests were performed according to CLSI guidelines. Molecular techniques were used to confirm resistance mechanisms. Univariate analysis and logistic regression were executed by EPI-INFO™7.2.

\textbf{Results}: Out of 54 infections, 31 were eligible (51.6% CRE-\textit{blaKPC}, 48.4% CRE-\textit{blaNDM}). 64.5% were male and median age was 71 years (IQR23). 38.7% (n=12) died before 14 days. Previous carbapenem use was related to CRE-\textit{blaNDM} (OR 6.5 [95% CI 1.3-33.0] \textit{p} 0.03). On the other hand, time to institution of definitive therapy was longer in CRE-\textit{blaNDM} episodes, albeit that, it did not reach statistical significance (8 vs. 7 days \textit{p} 0.07). Differences in shock at bacteremia onset, source of infection and effective empiric therapy were not evident. After adjusting analysis, only prior prescription of carbapenem (aOR 96.7 [95% CI 2.2-4169] \textit{p} 0.02) was linked to CRE-\textit{blaNDM} (Hosmer-Lemeshow \textit{chi}2 14.2 df 8 \textit{p} 0.07). None specific factor was associated to 14-day mortality, even more, this outcome was similar between both groups (OR 0.6 [95% CI 0.2-2.8] \textit{p} 0.5, logrank \textit{p} 0.9).

\textbf{Conclusions}: Our findings suggest that previous carbapenem use was strongly associated to CRE-\textit{blaNDM} bacteraemia. Nevertheless, no other differences could be spotted between both groups, including 14-day mortality. For the reasons given, we do not recommend guiding empirical treatments only by clinical features.

Abstract 5439

**Value of soluble programmed death-1 (sPD-1) and sPD-ligand-1 (sPD-L1) as early biomarkers for the post-surgical monitoring of cystic echinococcosis in Tunisian paediatric patients**

Eya Ben Salah*, Wahiba Sakly1, Coralie Barrera2, Sana Mosbahi1, Rabeb Farhani3, Anne-Pauline Bellanger4, Amine Ksia3, Bruno Gottstein5, Abdellatif Nouri3, Hamouda Babba1, Laurence Millon*

1Université de Monastir, Faculté de Pharmacie, Laboratoire de Parasitologie-Mycologie Médicale et Moléculaire, LR12ES08, 5000, Monastir, Tunisia; 2Chrono-Environnement UMR CNRS 6249, Bourgogne Franche-Comté University, Besançon, France; 3Paediatric Surgery Department, Fattouma Bourguiba Hospital, Monastir, Medical School, Tunisia; 4Chrono-Environnement UMR CNRS 6249, Bourgogne Franche-Comté University, Besançon, France; 5Institute for Infectious Diseases, Faculty of Medicine, University of Bern, 3001 Bern, Switzerland

**Background:** Cystic echinococcosis (CE) is a major health problem in African countries, including Tunisia. The post-surgical management of CE is facing relatively high rates of recurrences, which often could not be early detected by imaging techniques or available serological tests. Here, we evaluated the prognostic accuracy of laboratory tests including soluble programmed death-1 (sPD-1) and sPD-1 ligand (sPD-L1) in CE.

**Materials/methods:** A total of 62 Tunisian children (186 sera), surgically treated for CE and monitored for 1 post-operative year, were included in this prospective study. Twenty-six young patients presented pulmonary cysts, 18 and 16 cases had hepatic and multiple CE, respectively. Unusual localizations were detected only in two children (1 peritoneal lesion and 1 cyst located in spleen). Based on post-surgical outcomes and clinical courses of CE infection, patients were clustered into the cured CE group (CCE; n = 40) and the non-cured CE (NCCE; n = 22). For each patient, 3 plasma samples were obtained at the main time points of the follow-up period; 1 pre-operative sample (D0), 1-month (D30) and 1-year (D365) post-surgery specimens. Concentrations of sPD-1 and sPD-L1 were measured using ELISA commercial kits (Invitrogen, Thermo Fischer Scientific, Austria). We applied the Wilcoxon test to compare the expression levels of sPD-1 and sPD-L1 between the three points of time in the CCE and NCCE groups.

**Results:** Our results showed significant increase in sPD-1 levels 1-month after surgery compared to pre-operative titers (p = 0.004), followed by a considerable decrease after 1-year (p < 0.001), exclusively in CCE. Soluble PD-L1 exhibited significant decrease of levels 1-year in CCE group compared to 1-month concentrations (p = 0.04) but no significant difference was observed between pre-operative and 1-month levels. In contrast to CCE, the kinetics of both sPD-1 and sPD-L1 in NCCE group exhibited a similar pattern marked by unchanged levels throughout the whole monitoring period.

**Conclusions:** Our study revealed that sPD-1 showed a better performance than sPD-L1 for the post-surgical follow-up of CE cases, since it could clearly provide an early information regarding the effectiveness of therapy and the most probable clinical outcome of CE patients.

**Figure:** Evolution of sPD-1 (A) and sPD-L1 (B) levels during the monitoring period in CCE and NCCE patients. A. Median sPD-1 levels compared in CCE. a. D0 versus D30. b. D0/D30 vs D365. B. Median of sPD-L1 levels. c. compared in CCE D0/D30 vs D365. *P < 0.05; **P < 0.01, ***P < 0.001

Differences in the lower respiratory tract microbiota in patients with severe pneumonia of viral or bacterial origin

Jose Maria Marimon Ortiz De Zarate1*, Ana Perez-Gavilán1, María Ercibengo1, Nekane Azcue1, Marta Alonso1, Loreto Vidaur2

1Biodonostia, Infectious Diseases Area, Respiratory Infection and Antimicrobial Resistance Group, Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Microbiology Department, Donostia-San Sebastián, Spain, 2Biodonostia, Infectious Diseases Area, Respiratory Infection and Antimicrobial Resistance Group, Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Intensive Care Unit, Donostia-San Sebastián, Spain

Background: Composition of pulmonary microbiota of patients with severe pneumonia is still poorly known.

Materials/methods: Patients were involved in the study on the basis of clinical and radiological findings. Conventional microbiological studies included urinary antigen test for Streptococcus pneumoniae and Legionella pneumophila detection, blood and respiratory samples cultures and PCR for the detection of respiratory virus and some bacterial (atypical pneumonia) pathogens.

Mini-BAL samples of 11 patients with severe pneumonia admitted to the ICU between January and June 2019 were collected in the first 24 hours since initiation of antimicrobial treatment. Nucleic acids from 1 mL of the mini-BAL samples were extracted using the NUCLISENS easyMAG platform (bioMérieux). Microbiome was studied using the Ion 16S Metagenomics Kit (Thermo Fisher Scientific) that amplifies 7 hypervariable regions of the 16S rRNA gene. Libraries were sequenced in the Ion PGM sequencer and data analysed with the Ion Reporter software 5.1 using the consensus data of all variable regions. The study was approved by the regional Ethics Committee

Results: In 3 cases Influenza virus AH1 was detected, in 1 Influenza virus AH3, in 1 Respiratory syncytial virus (RSV), in 1 Rhinovirus, in 1 L. pneumophila and in 4 S. pneumoniae.

In the lung microbiome of patients with Influenza pneumonia there was a predominance of Firmicutes (mainly Streptococcus, Staphylococcus and Veillonella at the genus level) and Proteobacteria [Moraxella and Pelomonas at the genus level] [Figure]. Patients with RSV and Rhinovirus pneumonia showed more bacterial diversity at the phylum level. Patient 7, with L. pneumophila pneumonia showed 97.5% of Proteobacteria [95% Legionella]. Patient 8, with pneumococcal pneumonia showed a high proportion of Proteobacteria, but at the genus level had the same proportion of Streptococcus and Enterobacteria. The other 3 patients with pneumococcal pneumonia showed a clear predominance of Firmicutes [Streptococcus].

Conclusions: Severe bacterial pneumonia resulted in a respiratory microbiota characterized by the predominance of one phylum, the one causing the infection. The respiratory microbiome in patients with viral severe pneumonia showed a higher diversity. These differences can aid in the diagnosis and prognosis of severe pneumonia.

Microbiological features of vulvovaginitis in prepubescent girls

Maria Damalia1, Aggeliki Nikolakopoulou1, Christina Anthoulaki1, Ioulia Koumpi1, Eleni Prifti1, Lina Michala2, Natasa Loukopoulou1

1Alexandra General Hospital, Microbiology Department, Athens, Greece; 2Alexandra General Hospital, Department of pediatric and adolescent gynecology, Athens, Greece

Background: Vulvovaginitis is one of the most common gynecological conditions encountered in pediatric outpatient units. Aim of this study was to evaluate the prevalence of various microorganisms involved in the pathology of vulvovaginitis in girls of prepubertal age over a six-year period.

Materials/methods: A total of 442 girls were included, aged 1–10 years (mean age 6.7 years), presented in the outpatient department of pediatric and adolescent gynecology of our hospital, from January 2013 to December 2018, with signs and symptoms of vulvovaginitis. Vaginal swabs were placed in Stuart transport medium for culture and in normal saline for wet preparation. All samples were referred to microbiology laboratory where standard microbiological diagnostic procedures for bacterial and fungal pathogens were performed. Isolated microorganisms were identified using conventional methods. A rapid latex agglutination test was performed for identification of Lancefield A, B, C, D, F and G group antigens of streptococci (Avipath Strep, Omega Diagnostics). The microorganisms detected were classified as specific pathogens and potential pathogens (bacteria of fecal origin).

Results: Causative agents were isolated in 139/442 (31.4%) of girls studied, whereas in 303/442 (68.6%) no pathogens were identified. Of 139 culture-positive cases, specific pathogens were isolated in 52 (37.4%) and potential pathogens in 87 (62.6%). Specific pathogens were S. pyogenes 29/139 (20.9%), Haemophilus influenzae 11/139 (7.9%), S. aureus 5/139 (3.6%), Candida spp 4/139 (2.9%), Haemophilus parainfluenzae 3/139 (2.1%). Potential pathogens were Enterococcus spp 27/139 (19.4%), Escherichia coli 26/139 (18.7%), other Enterobacterales 23/139 (16.6%), S. agalactiae 9/139 (6.5%), Pseudomonas aeruginosa 2/139 (1.4%).

Conclusions:
1. In a high percentage (68.6%) of symptomatic cases of prepubertal vulvovaginitis no infectious pathogen was isolated.
2. The most common specific pathogen of pediatric vulvovaginitis is S. pyogenes followed by Haemophilus spp.
3. Bacteria of fecal origin are often found in vaginal cultures of prepubescent girls with vulvovaginitis and in these cases treatment should include counseling on vulvovaginal hygiene.
4. Candida spp is a rare cause of vulvovaginitis in prepubescent girls in the absence of predisposing factors.

Abstract 5442

Improvement of blood cultures processing with full automation in microbiology

Bianca Osnaghi1, Laura Vismara1, Paola Mirri1, Massimo De Paschale1, Arianna Gatti1, Serena Cavallari1, Paolo Melloni1, Emanuela Vasconi1, Lucia Rodolfi1, Maria Cassani1, Alessandra Bortignon1, Monica Barzani1, Maria Cozzi1, Vania Accardo1, Cristian Zago*1, Pierangelo Clerici1

1UOC Microbiologia, A.S.S.T Ovest Milanese, Legnano, Italy

Background: Sepsis is associated with an in-hospital mortality greater than 10%, which increases up to 40% in case of septic shock. The early administration of appropriate antibiotics in patients with severe sepsis and septic shock improves mortality, reduces length of hospital stay, and limits the development of antibiotic resistance. Our objective was to evaluate the impact of fully automation (WASPLab™ COPAN) to reduce the manual work and the turnaround time (TAT) for the preparation of Gram smears and culture set up for all positive BC bottles (BCs).

Materials/methods: a total of 100 BCs bottles from patients with suspected bacteremia were inserted 24/24 h into the BD Bactec®. On positive BCs, using a vacuum tube [COPAN BC+™] an aliquot of 2.5 mL was transferred from positive BC bottle to the BC+™ tube. The BC+™ tube was uploaded on WASPLab™ and Gram smears and culture set up (4 agar plates) was performed. Automatic streaking was performed with 10 µl loop and 4 quadrant streaking patterns. Only for Gram-negative bacteria, a preliminary AST (Vitek 2 CARD) was performed collecting an aliquot of blood culture from BC+™ tube to prepare a 1.5 Mac-Farland dilution. On the same tube, Real Time PCR molecular assays [CRE and Colistin-R ELITe MGB® kit, ELITechGroup Molecular Diagnostics] were performed. For the manual method, two drops of blood culture were used to inoculate each agar plate and one drop of BC was used to prepare manual smears.

Results: to process one BC bottle, the TAT monitored for whole process was 4 min while for manual procedure was exactly the double (8 min). To fill in the BC+™ tube the technician took 20 sec while with the routine method 1 min and 20 sec. Plate seeded by WASP™ had well isolated colonies and usually did not require a subculture. Good agreement between Manual and Automated smears was observed.

Conclusions: the introduction of BCs on WASPLab™ has significantly reduced manual work, has improved the quality of BCs streaking, and reduced the time to reporting. An automated protocol has a clear impact on quality and traceability.

Emergence of mcr-1 among diverse multidrug-resistant Escherichia coli in gulls from a coastal city uncovers potentially underestimated transmission routes

Marisa Almeida*1,2, Patricia Antunes1,3, Sofia Pereira2, Joana Freitas Da Silva2,4, Sofia Ribeiro1, Svetlana Ugarcina Perovic1, Angela Novais1, Paulo Martins Da Costa2,4, Luisa Maria Vieira Peixe1

1UCIBIO/REQUIMTE. Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, Portugal, Porto, Portugal, 2Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Portugal, Porto, Portugal, 3Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Portugal, Porto, Portugal, 4CIIMAR-Centro Interdisciplinar de Investigação Marinha e Ambiental, Universidade do Porto, Portugal, Porto, Portugal

Background: The emergence and spread of multidrug-resistant (MDR) bacteria to last-resource antibiotics like colistin is a global and multi-factorial phenomenon transversal to human-animal-food-environmental sectors. Mobile colistin resistance (mcr) genes have been detected in diverse ecological niches, including foodstuffs (e.g. pigs/rabbits/turkey/poultry), hospitalized patients, and sewage/effluents. However, the role of migratory birds as a source of mcr genes is missing. Gulls are increasingly present in big coastal cities, like Oporto, living as opportunistic scavengers in high contact with humans, raising new opportunities for bacteria transmission. This study investigates the presence and genetic background of mcr-carrying E. coli among gulls.

Materials/methods: Gull faecal samples (n=14) obtained in Matosinhos beach, between September 2018 and February 2019, were analysed. Resuscitation of samples (25 g) were performed in Buffered-Peptone-Water-BPW (37°C/1 h) before spreading in TBX-agar+colistin-3 mg/L. The identification of selected colonies (1-5/sample) were performed with MALDI-TOF MS and E. coli were screened for mcr-(1-5) genes. Isolates’ relatedness was examined by phylogenetic groups (PhG) and FT-IR spectroscopy. Antibiotic susceptibility profiles of mcr-1-positive isolates were determined by disk-diffusion or reference broth microdilution method (colistin) (EUCAST/CLSI). Plasmid characterization and location was performed by PCR-PBRT and S1-PFGE-hybridization.

Results: The occurrence of mcr-1 in gull samples was 28% (n=5/14), with 9 colistin-resistant E. coli isolates (MIC=4mg/L) recovered. Those isolates were distinguished in 7 FT-IR-groups belonging to PhG A (n=1), A/C (n=4; 3 samples), B1 (n=1), B2 (n=2; 1 sample) or F (n=1). Three commonly described mcr-associated plasmids were identified: IncHI2 (n=7), IncX4 (n=1) and IncI2 (n=1). Seven isolates were MDR, including to other clinically-relevant antibiotics (e.g. extended-spectrum cephalosporins and fluoroquinolones).

Conclusions: Gulls are an underestimated reservoir of E. coli carrying mcr-1 gene and potential vehicles for their dispersal to other bacteria and ecological niches. Transmission of mcr-1 gene from gulls to humans through contamination of bathing water sources [e.g. beach sand and sea water], food-chain [e.g. fish market] and urban environments [e.g. public water supplies, sewage/effluents] should not be disregarded. Global re-assessment of colistin use in food-animal production, monitorization of mcr in sentinel species, sewage/effluent treatments and programs for control of gull population are urgently needed in a One Health context.

Comparison of Hospital Resource Utilisation (HRU) among patients who received either ceftolozane-tazobactam (C/T) or meropenem in ASPECT-NP: a randomised, controlled, double-blind study of adult patients with Ventilated Nosocomial Pneumonia (V-NP)

Laura Puzniak*, Thomas Lodise†, Joe Yang†, Ryan Dillon†, Marin Kollef‡

1Merck & Co., Inc., Kenilworth, United States, 2Albany College of Pharmacy, Albany, United States, 3Washington University School of Medicine, St Louis, United States

Background: In ASPECT-NP, C/T 3000 mg q8h was non-inferior to meropenem 1000mg q8h for both 28-day all-cause mortality and clinical cure for the treatment of patients with V-NP. Given the substantial economic burden associated with V-NP, assessments of HRU were prospectively incorporated in the trial. This analysis compares HRU measures in patients who received C/T or meropenem in ASPECT-NP.

Materials/methods: Patients in the microbiological intent to treat (mITT) population (received ≥1 dose of study drug and had ≥1 Gram-negative pathogen[s] isolated from the lower respiratory tract at baseline, susceptible to at least one of the study drugs) were included. HRU measures collected post-randomisation until day 28 were hospital length of stay (LOS), ICU LOS, duration of mechanical ventilation (MV), and discharge/extubation status. HRU comparisons by key baseline covariates were also performed; results reported % and mean days.

Results: 511 patients (C/T=264, meropenem=247) were included. At enrollment, 100% were receiving MV, 385 (75.3%) had ventilator-associated pneumonia, and 474 (92.8%) were in the ICU. Average hospital LOS was approximately a day longer for C/T-treated patients (C/T: 22.0 days vs. meropenem: 21.1 days). There were fewer deaths in C/T versus meropenem (20.1% vs. 24.3%). More C/T-treated patients were discharged from the ICU (C/T: 57.3% vs meropenem: 54.6%). Among ICU discharged patients, C/T-treated patients were discharged earlier (C/T: day 13.7 vs. meropenem: day 15.2). A higher proportion of C/T treated patients were extubated by day 28 (51.9% vs. 48.2%). Among those extubated, C/T treated patients were extubated earlier (C/T: day 8.5 vs. meropenem: day 9.8). Fewer C/T-treated were re-intubated during the 28-day study period (C/T: 7.5% vs. meropenem: 10.0%). Among VABP (n=385), C/T-treated patients had a shorter ICU LOS (C/T: 16.5 days vs. meropenem: 18.1 days) and MV duration (C/T: 15.1 days vs. meropenem: 16.8 days). Among patients with Pseudomonas sp. (n=128), C/T treated patients had a shorter ICU LOS (C/T: 15.7 vs. meropenem: 18.5) days and MV duration (C/T: 13.3 vs. meropenem: 15.2) days.

Conclusions: Results suggest that C/T was associated with lower day 28 HRU relative to meropenem in the mITT population and among patients with VABP and Pseudomonas sp in ASPECT-NP.

Abstract 5448

Improvement of self efficacy and problem solving abilities in infection prevention staff, link nurses and physicians. Evaluation of a national workshop tour by the national hand hygiene campaign “AKTION SAUBERE HAENDE” in Germany

Karin Bunte1,2, Janine Walter1,2, Frank Schwab2,3, Alexander Gropmann2,3, Petra Gastmeier2,3, Tobias Kramer*1,2,3

1Charité Universitätsmedizin Berlin, national hand hygiene campaign „Aktion Saubere Hände”, Berlin, Germany, 2Charité Universitätsmedizin Berlin, Institute for hygiene and environmental medicine, Berlin, Germany, 3Charité Universitätsmedizin Berlin, National Reference Center for Surveillance of Nosocomial Infections, Berlin, Germany

Background: Effective sustainable implementation of infection prevention and control (IPC) often relies on designated link nurses and physicians. Those are usually healthcare workers (HCW) which are trained in a 40 hour course. We evaluated if a workshop primarily targeted at link staff performed on site could empower the target audience.

Materials/methods: We performed an anonymous online survey with a validated questionnaire consisting of 54 items in 31 German hospitals. The survey was sent to the local organizing committee for distribution to participants three months prior and after the date of the workshop. Only answers by HCW working either as IPC or in a link position were included into the analysis. In addition to structural parameters the questionnaire consisted mostly of closed questions with 5 step Likert scales. Those items were grouped into five different topics.

1. Knowledge on hand disinfection as an infection prevention measure
2. Capability to support HCW in improving their compliance to hand hygiene
3. Identifying risks for patient safety and providing adequate solution strategies
4. Persuasion that a constructive feedback culture is beneficial to patient safety
5. Awareness of the influence of communication on improvement of patient safety.

Scores for each topic were calculated and multivariate regression analyses were performed for each of the five topics to identify independent factors influencing scores.

Results: Of an approximate number of 918 participants, 389 answered prior to and 185 after the workshop. The majority of HCW chose the link position by themselves (69%) and was not select by superiors (70%). They identify with the link role (96%). While scores increased significantly for all five topics in the group after the workshop. Regression analysis identified timing of the survey after the workshop only to be independent factor for higher scores in topics 2-4. Being a link physician was independently associated with lower scores when compared to IPC staff.

Conclusions: The workshop was effective in empowering link HCW in areas. We identified that IPC staff in our sample were highly motivated and have chosen position on their own will. Link physicians were identified as a potential target group for future interventions.

Abstract 5449

**Duration of antibiotic prescription in the management of prosthetic joints infection in France: a national audit**

Marion Le Marechal*, Batailler Cecile1, Jean-François Gonzalez3, André Ferreira4, Anissa Belbachir5, Sebastien Lustig2, Tristan Ferry2, Johan Courjon1

1Hôpital l’Arche, CHU de Nice, Nice, France; 2CRIOAc de Lyon, Lyon, France; 3Hospital Pasteur, CHU de Nice, Nice, France; 4Société Française de la chirurgie de la hanche et du genou, Caluire, France; 5Anesthésistes Réanimateurs en Chirurgie Orthopédique et Traumatologique, Paris, France

**Background:** Prosthetic joint infections (PJI) are one of the most serious complication of arthroplasty. The management of PJI needs a multidisciplinary collaboration between, at least, orthopaedic surgeon, infectious disease specialist and microbiologist. The management of PJI in France is organized around reference centres named CRIOACs. Considering the heterogeneity of PJI and the global low level of evidence available, our main objective was to perform an audit through a questionnaire survey based on clinical case, to evaluate how French physicians manage in daily care PJI.

**Materials/methods:** Eligible participants were all physicians involved in care of patients presenting a PJI. Physicians could answer individually, or collectively during a multidisciplinary team meeting dedicated to PJI. The survey consisted as three questionnaires organized in a total of six clinical cases.

**Results:** Answers from the CRIOACs to the three questionnaires were 92%, 77%, and 53%. Respectively 65%, 58%, and 86% of respondents were answering as individuals.

After a 1-stage exchange surgery for a late *S. aureus* PJI, total antibiotic regimen duration was 4-6 weeks (16%), 6-8 weeks (49%), 8-12 weeks (33%), or six months (1%); and for a late *S. agalactia* PJI six weeks (37%), eight weeks (4%), or 12 weeks (59%).

After a 2-stage exchange surgery for a late *E. faecalis* PJI, total antibiotic regimen duration was eight weeks (six weeks between explantation and implantation, and two weeks after implantation) (45%), 10 weeks (5%), or 12 weeks (six weeks between explantation and implantation, and six weeks after implantation) (24%).
